For some reason not at first evident the greater portion of the manufacturing of the United States is carried on within an area bounded by lines connecting Portsmouth, N. H., Milwaukee, Wis., St. Louis, Mo., and Baltimore, Md. Since 1850 manufacturing investments in this territory have increased from a few hundred millions to more than twenty-five billions. The general reason for the growth in this limited area is the adaptability of the people to the climate and topography, with ample fuel and raw material supply. Intelligent white labor lives and thrives in a belt about two hundred miles north and south of the fiftieth isothermal degree from the Atlantic to the Mississippi River. Colored labor, Mexicans and the Japanese are available in the warmer sections of the country, so that it is possible to operate a plant irrespective of the latitude. Any town in the United States located on a railroad may have some natural product that can be manufactured into a useful material for home market or export.

Our climate varies from semi-tropical to cool-temperate. A business that requires much sunshine may be located in New Mexico, Arizona or California. For cotton manufacture, a high relative humidity is found along the Atlantic and Gulf coasts; if high altitude is essential this may be found in Salt Lake City, Denver and Cheyenne.

But natural elements are not all. The temper of a city is told by the spirit of its people. No prospective manufacturer wants to try to do business in a town which is itself antagonistic or indifferent. The founders of what has become a manufacturing business of national scope asked the leading men of a conservative Eastern city if they might locate a plant in that place. A negative answer was given, with the comment that "their town did not want the noise and smoke incident to the enterprise." It often occurs that the lives, happiness and well being of 10,000 people depend upon the main industry of the place.

A careful location study includes the foregoing and much more. Given the selection of a manufacturing site for a large industry, all good location areas should be investigated, and that one selected which seems to embody the greatest number of favorable factors.

WILLIAM MILLER BOOTH.

Syracuse, N. Y.

Report of Alien Property Custodian on the Metal Industry

CHAPTER III of the report recently made by the alien property custodian to the President contains a great many interesting revelations regarding the German domination of the metal markets of Europe, particularly those of zinc and lead. The intricate relationships existing between the numerous German-owned or controlled companies are shown graphically in the accompanying drawings.

While Germany has never been a great producer of metals, yielding only 3 per cent of the world's copper, 28 per cent of the refined zinc and 16 per cent of the lead, yet she has exercised almost complete control of the zinc and lead markets of the world outside the United States. The alien property custodian finds the secret of this power in the fact that the great German metal houses have acted in concert in the purchase of zinc and lead ores, control of smelters and refineries, and have been favored by unlimited credit from German banks.

The German metal triumvirate are the Metallgesellschaft of Frankfurt, Aron Hirsch & Sohn of Halberstadt, and Beer, Sondheimer & Co., of Frankfurt. These vast concerns developed out of very small ventures.

(1) *The Metallgesellschaft* is the largest of these concerns and is by far the most powerful metal concern in the world. It is a stock corporation with a capital of 18,000,000 marks. It is the outgrowth of the metal business founded by Philip Abram Cohn early in the nineteenth or late in the eighteenth century. In the early '60s of the last century, Henry Merton, whose real name was Moses and who was related to Philip Abram Cohn, founded a metal firm in London which later became the powerful house of Henry R. Merton & Co., Ltd. The Metallgesellschaft and the Merton firm worked hand in hand for the advancement of German domination of the metal markets of the world.

(2) *Aron Hirsch & Sohn*, a copartnership, is the business founded by Aron Hirsch and it has always been kept in the Hirsch family. This house has not confined itself strictly to metal trading but has also engaged in metal manufacturing. It has interests all over the world.

(3) *Beer, Sondheimer & Co.*, a copartnership, was founded in the latter part of the '70s by Messrs. Beer and Sondheimer, two salesmen of Metallgesellschaft, who broke away from the Metallgesellschaft and with the assistance of the Mitteldeutsche Credit Bank started in business for themselves under the name of Beer, Sondheimer & Co. This firm has confined its activities principally to the zinc smelting business.

The Zinc Syndicates

At the outbreak of the European war these three concerns controlled the zinc industry of the world with the exception of the United States. The control of the purchase of Australian ores was exercised by means of joint accounts resulting in the elimination of nearly all competition both in the purchase of ore and its allotment to European smelters.

This Australian zinc-ore purchase combine was followed by the formation of the German Zinc Syndicate, comprising all the large zinc concerns of Germany for the purpose of fixing prices in Germany. The formation of this syndicate was met by the formation of an English syndicate and a Belgian-French syndicate. The most important Belgian concern, however, the Société Vielle Montagne, which had extensive works throughout the world, was in a working agreement with the German Zinc Syndicate, so that the latter's preponderance over all the others was so great that they were forced to join the Germans in the formation of the International Zinc Syndicate in 1911. The purpose of the syndicate is stated as follows:

> A curtailment of production is to be effected whenever the stocks held by the various zinc smelters at the end of a quarter exceeds 50,000 tons; provided, however, that if the price of spelter in London should be £23 or more no curtailment of production is to take place.

Production and price were regulated and agreed upon from time to time according to the necessities of the market. The sale of the metal was placed in the hands of three principal German concerns which the alien property custodian designs as the triumvirate.

The Lead Syndicate

At the outbreak of the European war the lead output of the world was likewise centered in the hands of the Germans. The Metallgesellschaft had the exclusive sales agency of what was known as the international lead convention, which was formed in 1909 and continued thereafter for a number of years. It embraced the principal Australian lead producers, as well as most of the German, and most of the Spanish and Belgian lead mines. At least two American firms, to wit, the American Smelting & Refining Co. and American Metal Co., as far as their production of lead from ores imported in bond is concerned, and some of the Mexican mines, were likewise members of the syndicate which regulated output and fixed prices.

Copper

The situation in copper, however, was quite different, and the Germans were never able to get control of production. This was due largely to the fact that the United States output, which is more than 60 per cent of the world's total, could not be brought under German domination. Outside the United States, however, the Germans largely controlled the copper output. Germany also exercised a powerful influence over the price of the metal through the activities of the metal triumvirate, as well as because she was a large consumer.

The power which these concerns exercised in the market is believed to lie in the unlimited credit at their command for financing large purchases of copper for long periods of time, including periods of depression.

The German Metal Triumvirate in the United States

At the outbreak of the European war each member of this triumvirate had a branch of its business in the United States. The Metallgesellschaft had the American Metal Co., Aron Hirsch & Sohn had L. Vogelstein & Co., and Beer, Sondheimer & Co. had a branch under its own name. All these branches were located in New York City, and all developed vast and extensive interests in the United States, Mexico, and South America, including the control of mines, smelters, and refineries.

(*a*) *American Metal Co., Ltd.*—In or about the year 1887 Metallgesellschaft sent to the United States two of its representatives, to wit, Jacob Langeloth and Berthold Hochschild, to establish a branch of the Metallgesellschaft's business. At that time the present banking firm of Ladenburg, Thalmann & Co. were doing a metal business and had connections with the Metallgesellschaft. An arrangement was made resulting in the organization of a corporation called the American Metal Co., Ltd., under the laws of the State of New York, with a capital of $200,000, divided into 2,000 shares, to which corporation Ladenburg, Thalmann & Co. turned over their metal department. The stock of the corporation was issued as follows:

	Shares
Metallgesellschaft	600
Henry R. Merton & Co.	595
Ladenburg, Thalmann & Co.	710

The balance of the stock was allotted to various officers. It will be noted that from the very organization

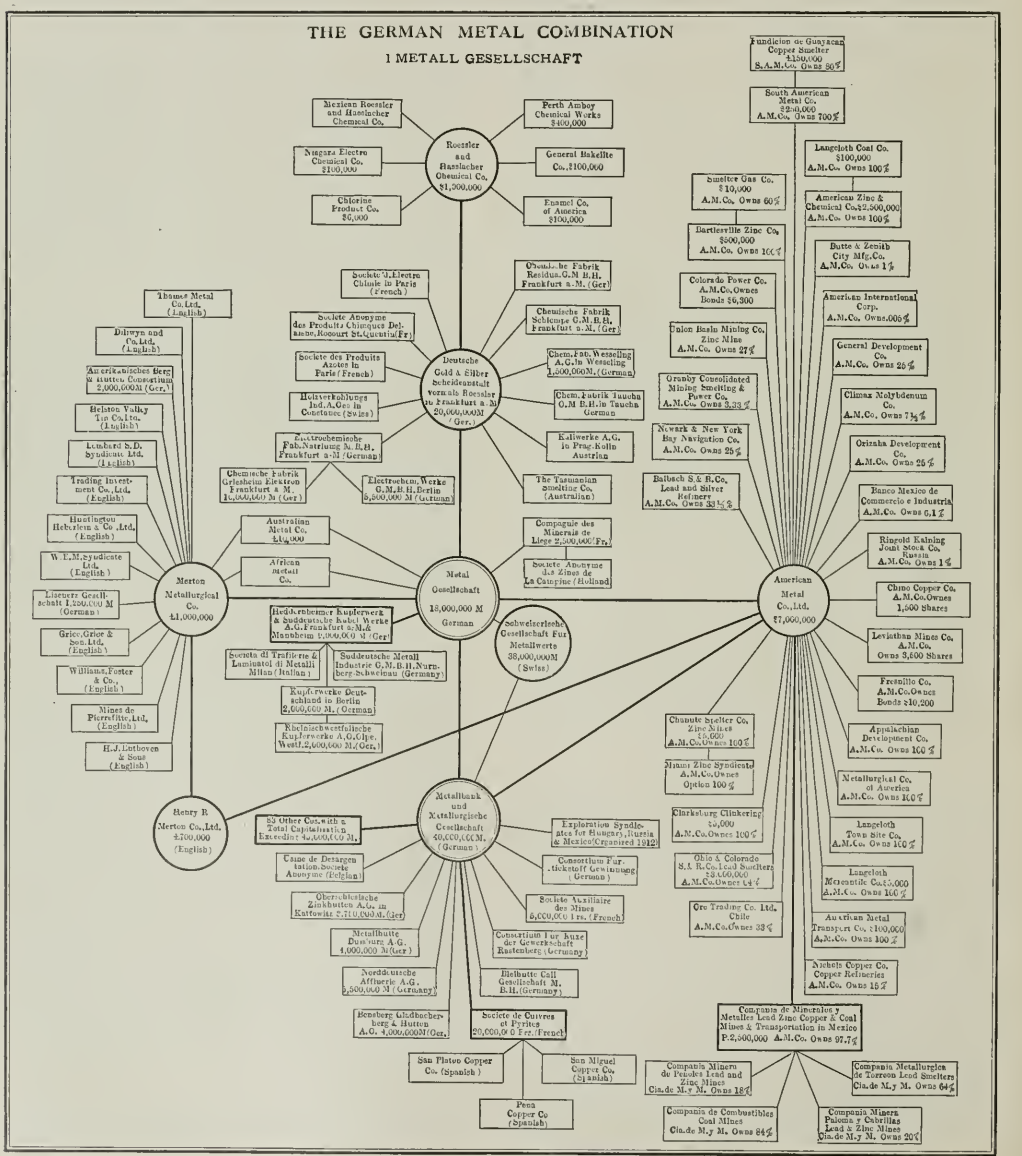
of the American Metal Co. the stock control thereof was in the hands of Henry R. Merton & Co. and the Metallgesellschaft. These German interests continued to retain that control through all the years of the development of the American Metal Co., and had the control at the outbreak of the European war. The capital stock of the American Metal Co. was increased from time to time until in 1917 it was $7,000,000.

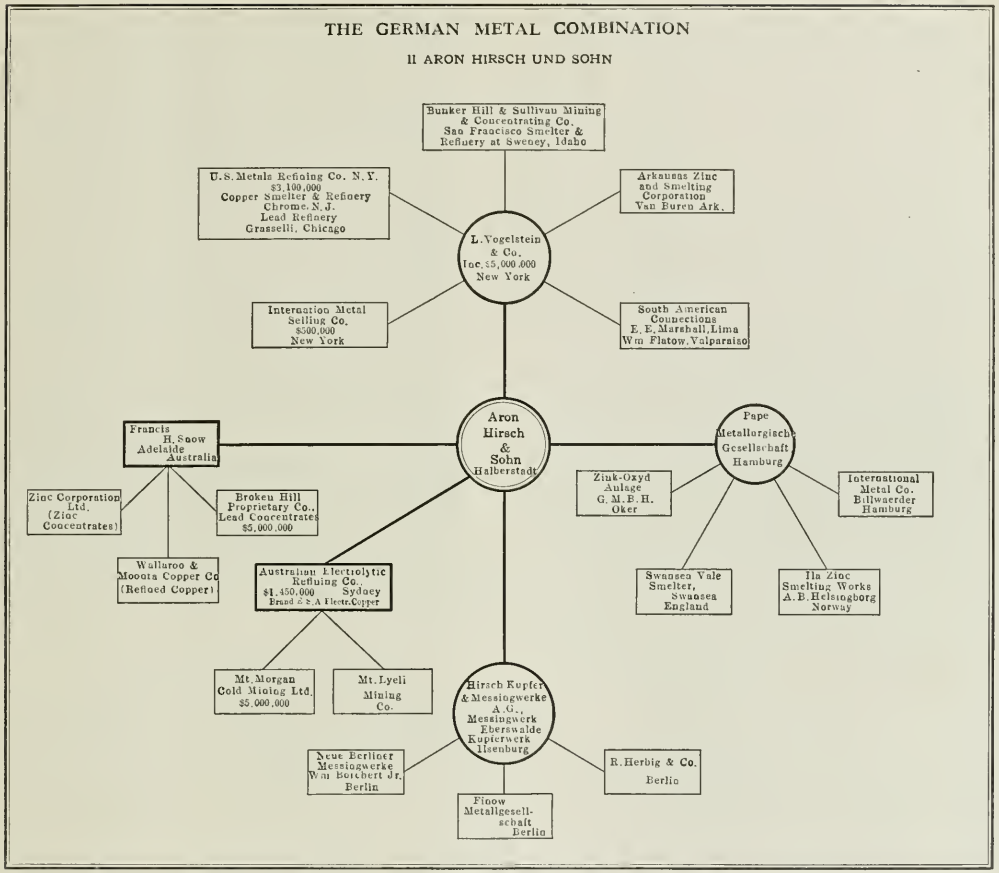
The entire turnover of the company in copper is about 250,000,000 lb. per annum, which is about 15 per cent of the country's total production of copper.

The report of the alien property custodian gives the following statements of average annual quantities of products of the American Metal Co.

Electrolytic copper	100/125,000,000 pounds
Zinc (spelter) all grades	75/100,000 tons
Bonded (Mexican) lead	50/75,000 "
Domestic lead	12/15,000 "
Sulphuric acid	80/100,000 "
White arsenic	4/6,000 "
Coal in Pennsylvania	350/400,000 "
Coal in Mexico	500/600,000 tons
Silver	12/15,000,000 ounces
Zinc oxide (Polar and Arctic brands)	7/10,000 tons
Zinc dust (American Extra Pure and Zenith brands)	3/4,000 "
Antimonial lead	1,000/1,500 "
Molybdenum concentrates	500/1,000 "

The zinc ores purchased by the American Metal Co. and treated by the smelters of its domestic subsidiaries for the two years ended June 30, 1917, amounted to approximately 1,700,000,000 lb. In addition to that





the company purchased spelter during those 2 years in the open market amounting approximately to 585,000,000 lb. The production of lead for 1917 was 168,000,000 pounds.

(*b*) *L. Vogelstein & Co., Inc.*—Aron Hirsch & Sohn was 10 years behind the Metallgesellschaft in establishing a branch in the United States. In 1897, Ludwig Vogelstein started an agency for Aron Hirsch & Sohn in New York. Soon thereafter Vogelstein formed the firm of L. Vogelstein & Co. and associated with himself one Ernest G. Hothorn. In the firm Aron Hirsch & Sohn had a direct interest. The business was conducted as a copartnership until the end of 1916, when the present corporation, L. Vogelstein & Co., Inc., was formed. During these 19 years the Vogelstein business was conducted purely as an agency of Aron Hirsch & Sohn. There were agreements between Vogelstein and the Hirsch concern for the division of profits upon the American business and upon some of the European business.

The more important activities of the Vogelstein concern comprised the erection of a copper refinery at Chrome, N. J., in co-operation with Capt. J. R. DeLamar; the organization of the International Metals Selling Co. to facilitate the sale of the refinery's product; and arrangement with the American Zinc, Lead & Smelting Co. for the sole sale agency of that concern; the organization of the Arkansas Zinc & Smelting Corp. and the erection of a zinc smelting plant; and contracts with other smelters and refineries for exclusive selling agencies.

The total annual turnover during the last five years was as follows:

Copper (870,931,737 lb.)	$207,196,741.36
Gold (578,138,191 oz.)	11,870,104.67
Silver (25,120,134.16 oz.)	17,166,113.45
Lead (323,099,014 lb.)	18,320,735.68
Spelter (397,740,356 lb.)	47,814,011.40
Tin (91,128,623 lb.)	37,035,647.83
Miscellaneous	3,134,834.31
	$342,538,188.70

(*c*) *Beer, Sondheimer & Co., Inc.*—Beer, Sondheimer & Co. of Frankfurt established a New York branch in 1906. Like the Metallgesellschaft, it sent over two young men, Benno Elkan and Otto Frohnknecht, who established the business here under the name of Beer, Sondheimer & Co., American Agency. The name was subsequently changed to Beer, Sondheimer & Co., American Branch, and the business was conducted under that name until August, 1915, when it was incorporated, under circumstances which will be hereinafter discussed. The New York business was owned at all times by the Frankfurt house, Elkan and Frohnknecht being only agents upon a salary and a profit-sharing basis. The ramifications of the company in the metal business are shown in the chart.

The following table shows copper, spelter and lead turnover of Beer, Sondheimer & Co. for several years:

TOTAL TURNOVER

	Lb.	Value
Spelter dealt in:		
1915	73,143,943	$8,118,004
1916	75,563,802	10,342,882
1917	57,459,556	5,330,090
1918	49,814,465	4,131,826
Total	255,981,766	$27,922,802
Lead dealt in:		
1915	6,210,758	278,716
1916	5,754,419	378,096
1917	6,230,411	527,232
1918	673,727	70,539
Total	18,869,315	$1,254,583
Copper dealt in:		
1915	17,071,632	2,559,490
1916	24,295,095	5,530,191
1917	27,056,933	7,326,273
1918	10,450,315	2,627,004
Total	78,873,975	$18,052,958

Minerals-Separation Agency

The history of Beer, Sondheimer & Co.'s activities in the United States would not be complete without mentioning its connection with the various minerals-separation companies.

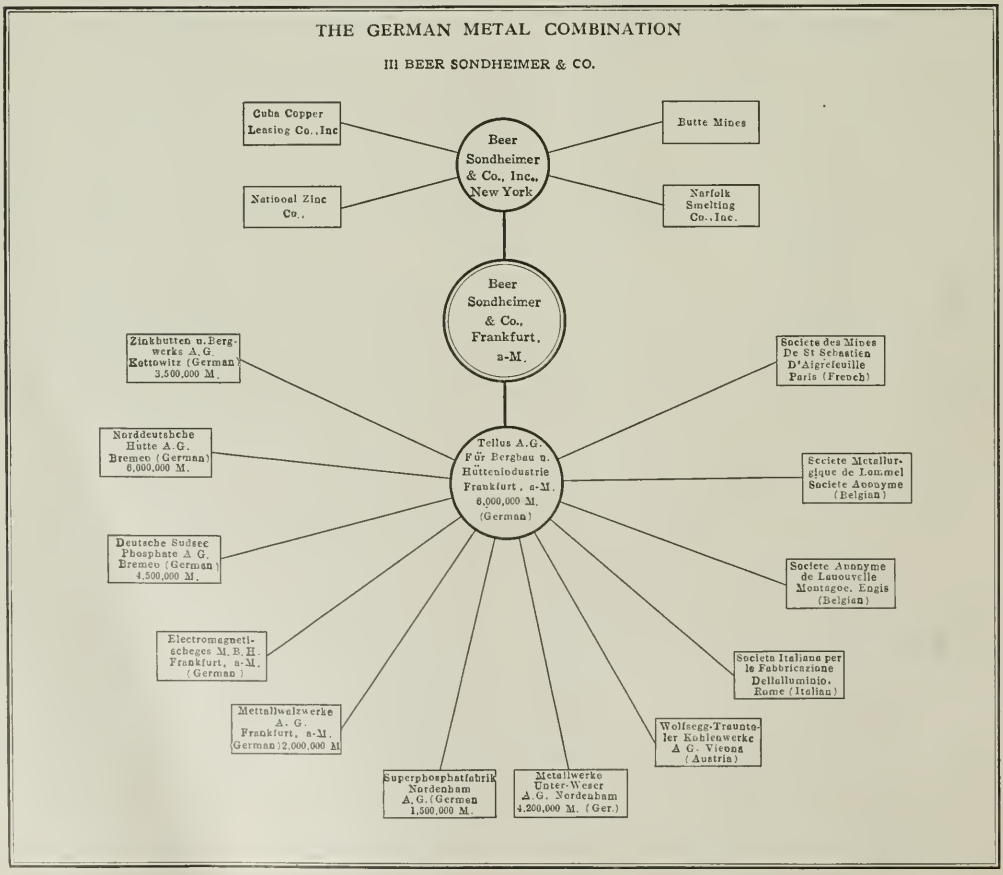
In 1906, Henry Livingstone Sulman, Hugh Fitzalis, Kirkpatrick Picard, and John Ballot, all of London, England, claiming to be the inventors of the new process, obtained a patent thereon in the United States. In 1910, Sulman and Henry Howard Greenway and Arthur Howard Higgins, all of London, obtained another patent in the United States, and in 1914, Greenway, then of Melbourne, Australia, obtained a third patent in the United States, the latter two patents involving the same process as the first one, but including improvements thereon. These patents run for a period of 17 years from their respective dates.

In 1905, and before the first United States patent was obtained, the patentees obtained a patent in England exactly similar to the first United States patent. The validity of the English patent was attacked in the English courts, but was sustained by the House of Lords. (Minerals Separation, Ltd. vs. British Ore Concentration Syndicate Ltd., 27 R. P. C., 33.)

In 1903, Minerals Separation, Ltd., which will be hereafter designated as the parent company, was formed under the English law. The three United States patents were assigned to this company.

In 1910, the parent company having acquired the United States patents, and similar patents obtained in Canada and Mexico, conveyed these patents to a corporation called Minerals Separation American Syndicate, Ltd., for the purpose of enabling the American syndicate to exploit these patents in America. This, too, was an English corporation.

In 1911 the American syndicate made a contract with Beer, Sondheimer & Co., whereby it gave to that firm the exclusive agency to represent the syndicate in America. For reasons which are unimportant to the present inquiry, this first American syndicate was soon dissolved and a new syndicate was formed, called Minerals Separation American Syndicate, 1913, Ltd. This, too, was a British company. The 1913 syndicate renewed the agency agreement of Beer, Sondheimer & Co., and appointed that firm sole agents to conduct all



of the syndicate's commercial affairs in the United States, Canada and Mexico, the agency to continue for a minimum period of 10 years with a provision for renewal for the rest of the life of the patents. Beer, Sondheimer & Co. were to receive a commission of 10 per cent of all gross royalties received for the use of the patents and 10 per cent on all profit-sharing business (the syndicate intending not only to give licenses, but also to buy up and treat ores), and also a percentage as a commission of the sale of products so treated by the syndicate.

When the agency agreement was made Beer, Sondheimer & Co. had an American branch of its business in New York City, which was in charge of Benno Elkan and Otto Frohnknecht, and was being conducted under the name of Beer, Sondheimer & Co., American Branch. The parties entered into the performance of the agreement, and inasmuch as most if not all of the business was done in the United States the agent's end of the business was conducted by the American branch of Beer, Sondheimer & Co.

In addition to having the exclusive agency, Beer, Sondheimer & Co. were also stockholders of the 1913 syndicate, owning 32,615 shares of said stock. In 1916 the property of the 1913 syndicate was conveyed to an American corporation called Minerals Separation North American Corporation, and each stockholder became entitled to two shares of the American corporation's stock for each share of the 1913 syndicate stock.

The importance of the control by this German-owned branch of Beer, Sondheimer & Co. of the minerals-separation process, and the power to grant or withhold from the United States metal-industry licenses to use the flotation process, can hardly be overestimated. The custodian, as will be pointed out later, has taken over all of the minerals-separation stock held by Beer, Sondheimer & Co., and the latter's control of the minerals-separation process in the United States has broken.

Disclosures by Investigations Conducted by Alien Property Custodian

After the passage of the trading with the enemy act in October, 1917, and the subsequent appointment of the alien property custodian, he caused investigations to be made of the American Metal Co., Vogelstein & Co., and Beer, Sondheimer & Co., as a result of which he took over the entire business of Vogelstein & Co. and of Beer, Sondheimer & Co. and 49 per cent of the stock of the American Metal Co. The investigations disclosed the following state of facts:

As to Beer, Sondheimer & Co. it was shown that legal subterfuges were adopted for the express purpose of making it impossible for the United States Government in case of war between the United States and Germany to exercise its belligerent rights and take control of enemy property in the United States. It was further disclosed that Messrs. Elkan and Frohnknecht were citizens of the United States; they did not become such until 1917. One of them became a citizen after Von Bernstoff got his passports and the other after we were at war with Germany. "There is evidence to indicate that their sudden desire to embrace our citizenship was only a 'war measure' after all and that they asked for and obtained the approval of the Frankfurt firm to their action."

As a result of his investigations the alien property custodian demanded and took over the entire business assets of Beer, Sondheimer and Co. as German property.

As to L. Vogelstein & Co., the alien property custodian has taken control of the business and is in possession of the entire capital stock, including the interest of Aron Hirsch & Sohn.

As to the American Metal Co., the alien property custodian demanded and received all of the 34,644 shares of stock owned by the Germans and appointed 5 out of the 15 directors of the company to represent him in the conduct of the affairs of the corporation.

As to Beer, Sondheimer & Co.—The business of Beer, Sondheimer & Co. is in process of liquidation. This includes not only the corporation Beer, Sondheimer & Co., Inc., but also its subsidiaries, the National Zinc Co., the Norfolk Smelting Co., and the Cuba Copper Leasing Co. It includes also the 100,000 shares of the stock of Minerals Separation North American Corporation out of a total issue of 500,000 shares. This stock will be disposed of by the custodian and will go into American hands.

As to Vogelstein & Co.—As in the case of Beer, Sondheimer & Co., when the custodian took over the business of L. Vogelstein & Co., Inc., he placed in control thereof a board of directors designated by him. Subsequent investigation by the custodian disclosed that Vogelstein, who was a naturalized American citizen, had a preponderating interest in the assets of the corporation, and inasmuch as it has as yet been impossible to obtain from Aron Hirsch & Sohn an accounting so as to determine that concern's exact interest in the assets of L. Vogelstein & Co., Inc., an arrangement has been perfected between the custodian and Vogelstein whereby all of the stock of the corporation has been put into a voting trust for a period of five years, the custodian naming two of the three voting trustees. Thus the control of the corporation for the next five years will be in the hands of trustees appointed by the alien property custodian. Vogelstein has agreed not to resume his relations with the Germans during this period of five years and to conduct the business of the corporation as a purely American concern. Vogelstein has agreed to pay to the custodian $1,668,671.49, being the amount of the apparent indebtedness from him to the Hirsches as of April 30, 1916, and has agreed to pay to the custodian all additional moneys that may be found to be due to the Hirsches upon a final accounting which is to be had within six months after the declaration of peace. Thus circumscribed and guarded, the control of the business has been turned back to Vogelstein, the custodian retaining two out of the five places on the board of directors as long as the custodian may have any interest in the business.

Stock Put in a Voting Trust

As to American Metal Co.—Soon after the trading-with-the-enemy act became a law, the Americans in control of the American Metal Co. not only promptly filed the report required by the act and disclosed therein the German ownership of about 49 per cent of the stock of the company, but offered to co-operate with the custodian in any direction looking to the elimination of the German interests. An investigation of the affairs of the company was courted and at the instance of the War Trade Board such an investigation was made and subsequently the alien property custodian likewise made an investigation of his own. The officers of the company heartily co-operated with the alien property custodian, which resulted in the first instance in the transfer to the custodian of the stock belonging to the Germans. The custodian was satisfied with the good faith of the management of the corporation and therefore designated but five out of the 15 directors of the company.

By agreement between the alien property custodian and the American stockholders, together controlling 53,264 shares (out of 70,000 shares outstanding) all of said stock has been placed in a voting trust for a period of five years. The alien property custodian is entitled to receive voting trust certificates representing the 34,644 shares of stock formerly held by enemy aliens. It is his purpose to offer these certificates for sale to the American public at public auction.

The policy of the alien property custodian to sell only to Americans will be strictly adhered to in this instance, and none of the voting trust certificates will be permitted to go into any but American ownership. The immediate result is that 76 per cent of the stock of the company will be owned by American citizens. The alien property custodian is in correspondence with the British authorities with a view to the deposit under the voting-trust agreement of the 16,736 shares held by Henry R. Merton & Co. and its allied interests. It is hoped that such action will be taken in the near future. When this has been done, the alien property custodian believes that all German ownership and influence will be effectually eliminated from the company.

Supreme Court Hears Minerals Separation vs. Butte & Superior

THE argument before the U. S. Supreme Court in the Minerals Separation vs. Butte & Superior infringement suit was heard on Wednesday, March 19. No extension of time was requested, as in the Hyde case, and there were no experimental demonstrations, as in that case. The plaintiff, Minerals Separation, divided its time into an opening and a closing, half an hour each; defendant, Butte & Superior, having the intervening hour.

In opening, counsel for Minerals Separation explained to the court that in the Hyde case the question before the Supreme Court had been as to the validity of the patent (835,120), the acts of infringement in that case having been clear. In the instant case, however, the Supreme Court having established the validity of the patent, the question before the court is as to the infringing nature of the defendant, who, previous to the Supreme Court decision, had been using about two-tenths of 1 per cent of pine oil, alone, as the flotation agent, but who immediately upon the Supreme Court's finding in favor of the validity of the patent, had, while continuing the use of the pine oil, to very little more than two-tenths previously used, added thereto eight-tenths of 1 per cent of petroleum oils, which the District Court, after a lengthy hearing, had found to be utterly useless as a frothing agent, and as the defendant had admitted was a wasteful use of oil.

Several of the Justices questioned counsel as to the limiting amount of the process, recalling to mind the colloquy which had taken place in the Hyde case, which colloquy was so prominently set forth in the opinion of the Court of Appeals in the present case. Counsel claimed that in that case counsel for plaintiff had been speaking of the use of oleic acid upon Broken Hill ore, and that the patent explained that for different ores and different oils, different proportions were required, and that the proper proportions in each case could only be ascertained by experiment. In argument, and in response to inquiry from the Justices, counsel for Minerals Separation insisted that these petroleum oils were absolutely useless as frothing agents and even actually harmful, so that the pine oil, which had previously done the work and was still doing the work, had to be slightly increased.

Counsel for the defendant, Butte & Superior, in opening stated that he came before the court with no intention whatever of questioning the court's decision in its sustaining the validity of this patent. He was anxious, he said, to assist the court in interpreting its decision, and with this end in view would recall the subject as it was presented to the court, going quite fully into the emphasis which had, in the Hyde case, been placed upon the "critical" proportions of oil, the minute, microscopic quantities, and showed that plaintiff's experts, as well as the patent itself, confined the process to these minute quantities; the plaintiff's own witnesses having testified that for all ores and all oils the world over, the proportions varied between 0.05 and 0.2 per cent. The colloquy of the Hyde case was also quite fully quoted.

The counsel for the defendant then took up the question as to the use of petroleum oil in flotation practice, showing the very general use of just such mixtures as defendant is now using, of mixtures of vegetable and mineral oils, and in the same relative proportions, by the licensees of Minerals Separation. He also quoted from the testimony of complainant's own witnesses as to the beneficial use of petroleum oils, and quoted the original English patent in which oleic acid and petrol are always specified together as absolutely equivalent. The first written report of the discovery also was quoted as showing the fact that petroleum oils were suitable oils.

The question as to the delay in filing a proper disclaimer of the three "small quantity" of oil claims was then taken up by counsel for defendant, who claimed that the disclaimer as filed was in fact no disclaimer whatever, but actually broadened the three claims in question by a tricky use of the wording of the Supreme Court decision in the Hyde case, in which the Supreme Court said: "The patent must be confined to the results obtained by the use of oil within the proportions often described as in the testimony and in the claims of the patent as 'critical proportions.'"

In the disclaimer they so repeated the words, "results obtained," as to make the disclaimer read that these claims are limited to a process in which the "results obtained are the results obtained by the use of" the critical proportions of oil. From this counsel argued that according to the statutes covering the question of disclaimer, the plaintiff, having up to this time in fact made no disclaimer, has no right to maintain a suit upon this patent.

In closing argument, counsel for plaintiff urged strongly the position that the use of petroleum in such manner did not conform to the prior art, as prior art was classified by the Supreme Court decision in the Hyde case. Oils, it was argued, have other necessary qualities than the "preferential affinity" referred to, as for example in Cuttermole process the additional property of forming granules. In this case the frothing quality was lacking for defendant's ore, citing an experiment before the District Court and claiming that defendant had never in its practice used petroleum oil alone. The gist of the Minerals Separation argument was that, when an oil will not effectuate, the process of the patent in suit, it is not an oil of the process. That appears to be that for one ore petroleum may be an oil of the process, while for another ore it may not be an oil of the process.

As to the disclaimer, the counsel for the plaintiff said that the "small quantity" claims 9, 10 and 11 were of a group different from all the other claims of the patent in that they were not limited, as the other claims of the patent, to a process which is obtained as the result of a froth formed by oil-coated mineral matters.

Arguments upon both sides were very able, and while one may question the advisability of attempting, in so limited a time, to cover so wide a subject as this case presents, it is perfectly clear that it was not possible even to touch upon many of its important features. The Justices were most attentive, showing an unusually keen interest from the very first word to the end of the arguments.

Civil Service Examinations

The United States Civil Service Commission announces open competitive examinations for junior metallurgist and junior mining engineer, for men only, April 15, 1919. Entrance salary, $1200 to $1500 a year. There are vacancies at Seattle, Wash., and Pittsburgh, Pa.

New General Import License

The necessity of obtaining individual licenses for the importation of unrestricted commodities from the United Kingdom, France, Italy or Belgium, or any of their possessions, may be avoided by using the general import license PBF 34, issued by the War Trade Board on March 6.

The following restricted commodities are expressly excluded from the terms of this license: Pig tin, tin ore, tin concentrates, all metal alloys containing more than 20 per cent tin, spiegeleisen, ferromanganese, emery, except that produced in Canada; salvarsan, neosalvarsan, arsephenamine, and all substitutes therefor and equivalents thereof; nitrate of soda, sugar.

Manganese and Chromium in California

Owing to the increased interest in manganese and chromium during the period of the war, all known deposits in California were visited and examined by members of the field staff of the State Mining Bureau. The results of these investigations are embodied in Bulletin No. 76, which may be obtained for 50c. postpaid, from the State Mining Bureau, Ferry Building, San Francisco.

As this is the only recent publication giving detailed data on the manganese and chromium resources of the entire State, it is still of value, in spite of the fact that the situation which led to the investigations no longer exists.

Waste Paper-Mill Bark as a Source of Tannin

The feasibility of using waste hemlock bark from paper-mill operations for tanning purposes has been further demonstrated in recent tests made by the Forest Products Laboratory. Results obtained first in an experimental way were so encouraging that the investigation was finally carried out on a semi-commercial scale in co-operation with a paper mill, a tannery and a manufacturer of drying equipment.

The conclusions reached are : (1) no great technical difficulties stand in the way of utilizing paper-mill bark for such purposes; (2) the product is satisfactory from the tanner's standpoint; (3) it can be prepared at a cost which will allow it to compete with leaf bark.

The use of paper-mill bark for tannin would mean a source of income for the paper mill from a material which is now of little or no value. In many cases it would also be the solution of a serious problem of stream pollution. The tanner would be assured of a constant supply of dried bark which would allow him to keep much less material in stock, to reduce his fire hazard and to wipe out the depreciation and interest charges which must be carried against a yard full of leaf bark. The lumberman would avoid increasing difficulties of obtaining satisfactory labor for bark peeling and would do away with the fire hazard and expense incidental to the peeling and seasoning operations, all of which combine to make the production of leaf bark an unsatisfactory business, even at the present market price.

It is believed, therefore, that utilization of waste paper-mill bark for tannin is a conservation measure which from every standpoint is worthy of being put into immediate practice.

Exhibit on Method of Classification of Personnel

Employers and others interested in personnel work will have an opportunity to examine the methods developed by the Committee on Classification of Personnel in the Army at an exhibit to be shown on the third floor of the Engineering Societies Building, 29 West 39th Street, New York City, April 1 to 12. The exhibit consists of a collection of wall charts, forms, photographs and models showing how the Army finds out what men can do best and how it uses that information; how soldiers are trade-tested, and how officers are rated and fitted into place; how the work is checked and supervised, and its results in the war. The collection is being shown under the auspices of the National Association of Corporation Schools and the United Engineering Society.

Opportunities for Disabled Men

The Federal Board for Vocational Education has suggested the positions of safety engineer and safety inspector as being suitable for men who have lost one eye or one arm but who still retain fair hearing and the use of both legs. Opportunities for work are numerous, as insurance companies, large industrial concerns, the Interstate Commerce Commission and various State and municipal departments offer good positions of this sort. The salary of the safety inspector will range from $1200 to $2000 a year and the course of training should be not less than three months, while those wishing to qualify as safety engineers, with a salary range from $1800 to $3000 per year, should continue their studies for at least six months.

Surplus Acid in the War Department

The Director of Sales, War Department, states that approximate quantities of surplus acid held by the Department on March 13 were as follows:

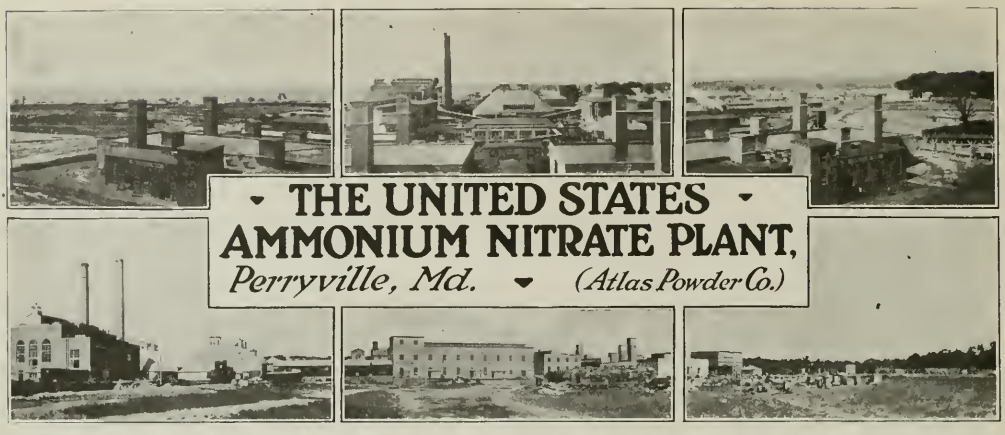
Sulphuric acid	4400 tons
Oleum	300 tons
Nitric acid	1000 tons
Mixed acid	2600 tons
Spent acid	700 tons

These quantities are very small compared with the total production and consumption of the country, nevertheless the Government will not dispose of it in such a way as to affect the market seriously.

Expansion of Japan's Trade During the War

A detailed trade study of Japan for the years 1913 to 1917 just issued by the United States Tariff Commission indicates striking changes in the commerce, industry and financial position of that country during the war period. Japan's total trade rose from $680,500,000 in 1913, to $1,319,000,000 in 1917, an increase of 94 per cent.

A special section of the report is devoted to the trade between Japan and the United States, from which it appears that at present the United States supplies a little over one-third of Japanese imports and takes nearly 30 per cent of Japan's exports. The sales to Japan consist mainly of ginned cotton, iron and steel, construction materials, machines and engines, and petroleum, while the purchases from Japan are made up principally of raw silk, silk tissues, tea, hemp and straw braids for making hats, champhor, beans and peas, porcelain, starch, buttons, surgical instruments and matches.



A Description of the Manufacture of Ammonium Nitrate by the Double Decomposition of Chilean Saltpeter and Ammonium Sulphate—Phases, Their Control and Application—Plant Operations

UP TO the present there have been military reasons for close secrecy about the Government ammonium nitrate plant at Perryville, Md., which was speedily constructed last spring. It was put into operation on July 20, replacing in about 100 days, with an enormous plant built of concrete, tile and steel, the green fields of a plantation famed since Colonial days for its fine view of the wide waters to the south, where Chesapeake Bay suddenly tapers into the gigantic Susquehanna River. The site was chosen because it offered most ample facilities for receiving great quantities of raw materials such as Chilean saltpeter at port, sulphate of ammonia from the coke-oven region by rail through the uncongested Susquehanna Valley route of the Pennsylvania R.R., coal and abundance of fresh water. Oil of vitriol, the so-called universal chemical manufacturing reagent, has not been listed, because no such intermediary is required for performing the direct cyclic process used in this operation and which was devised by Freeth and Cocksedge,[1] so that the following simple equilibrium is forced to the right, giving sufficiently pure needle ammonium nitrate by the double decomposition of the reciprocal salt-pairs. The common ammonium and nitrate salts of commerce are utilized without making any intermediates such as nitric acid or ammonium hydroxide.

$$2NaNO_3 + (NH_4)_2SO_4 \rightleftarrows Na_2SO_4 + 2NH_4NO_3.$$

Another process[2] somewhat similar has been described as operated in France, making use of the Solvay ammonium chloride liquor obtained from the familiar salt-ammonia-carbonate process for making sodium bicarbonate according to the reactions:

$$NaCl + NH_4OH + CO_2 \rightleftarrows NaHCO_3 + NH_4Cl,$$
$$NH_4Cl + NaNO_3 \rightleftarrows NaCl + NH_4NO_3.$$

[1]U. S. Pat. 1,051,097—1913. British Pats. 16,454—1910; 12,401—1915.

[2]Etude d'une Double Decomposition Saline Reversible. Par E. Rengade. Revue général des Sciences pures et appliquées. No. 17-18, Page 489-503, Sept. 1917.

The Germans are reported to have substituted the sodium chloride in the Solvay reaction with sodium nitrate and obtained ammonium nitrate liquor[3] directly, but this process could not have become of great importance with them, because of their shortage of crude Chilean nitrate salts. It was thought that the cost of carbon dioxide and lime, together with the manufacture of the accompanying complicated equipment necessary for the performance of the process, rendered this reaction of little use in such an emergency as existed during the days when the U. S. Ordnance Department had to create a munition industry with the greatest speed possible. Furthermore, the bicarbonate crystallized out is contaminated with several other salts and cannot be marketed directly as obtained.

The solubility curves in Fig. 1 indicate the ratio of each of the four salts involved in the equilibrium to 100 parts of water in single solution from 0 to 100 deg. C. In the case of the mixed-salts solutions, the saturation solubilities fall below the respective single solute curves in accordance with the law of the solubility-products of the constituent ions: NH_4, Na, NO_3 and SO_4. Groups 0 and 3 are examples of saturated concentrations which clearly indicate the depression of the ions by the drop in the points 0 and 3, (—, b and c) below the respective curves, Fig. 1, in the NH_4NO_3 — $NaNO_3$ — Na_2SO_4 salt system as actually used in the cycle operation of the sulphate-nitrate process of Freeth and Cocksedge. Besides the three well-known anhydrous, hepta- and deca-hydrous phases of sodium sulphate and the five enantiotropic crystalline phases of ammonium nitrate, the following four double salts exist to complicate matters and give impure yields:

$$Na_2SO_4 \cdot NaNO_3 \cdot H_2O,$$
$$Na_2SO_4 \cdot (NH_4)_2SO_4 \cdot 4H_2O,$$
$$(NH_4)_2SO_4 \cdot 2NH_4NO_3,$$
$$(NH_4)_2SO_4 \cdot 3NH_4NO_3.$$

WASTE SULPHATE CONVEYOR WITH TRUCK LOADING ARRANGEMENTS

In the absence of a temperature-concentration chart showing the stability areas and equilibrium loci of this very complicated polyphase system only a brief account of the five forms of ammonium nitrate and their application in the manufacture of the explosive trinitrotoluene mixture called amatol will be given. A description of the plant equipment and operation will follow. The feature of the plant, the control of the temperature of the crystallizing liquors, will be completely treated in a separate article in a following issue.

Phases of Ammonium Nitrate

The four transition points of the five crystalline phases of ammonium nitrate are at —16, 32, 84 and 125 deg. C. The form existing below —16 deg. C. has no practical application and need not be described in this paper. The needle crystalline form, scientifically named beta-rhombic, is the usual and important salt, being stable from —16 to 32 deg. C. Its density as determined by flotation is 1.725 at 25 deg. C. Needle crystals have the exclusive commercial advantage of not caking into hard masses when stored and can be conveniently handled when the salt has not been allowed to become saturated with hygroscopic moisture. When heated through 33 deg. C., beta-rhombic crystals are immediately converted into alpha-rhombic crystals, a pseudomorph, that is, an aggregate of fine crystal particles of a new individual form but which retain the general external facial appearance of the original needle crystals. If the needles are stirred during heating, they break down into a very fine powder and when stored in the presence of moisture, harden together into a white opaque stone-like mass. The change in form is accompanied by about 3 per cent expansion, the density of the alpha crystals being 1.66. If a block of needle ammonium nitrate is heated and cooled through the transition temperatures (33-31 deg. C.), the permanent expansion sets up voids so that the block becomes spongy. After repeated heating and cooling the block will disintegrate. Because of the tendency to cake into a hardened mass in the presence of moisture, alpha-rhombic crystals are an undesirable commercial form. When a large amount of alpha crystals are allowed to cool, the temperature can be observed to stand at 31 deg. C. for a considerable period. The latent heat of the change from alpha- to beta-rhombic crystals has been determined to be 5 calories per gram, which is a considerable heat quantity in comparison to the low specific heat of such salts.

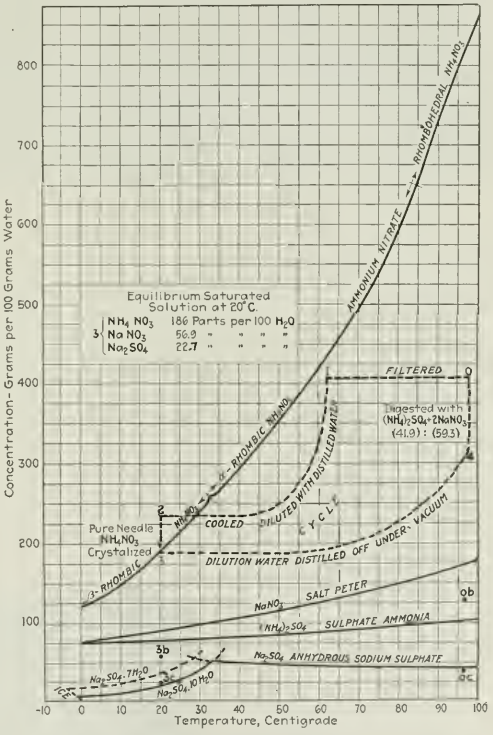

FIG. 1. SOLUBILITY CURVES AND PROCESS CYCLE

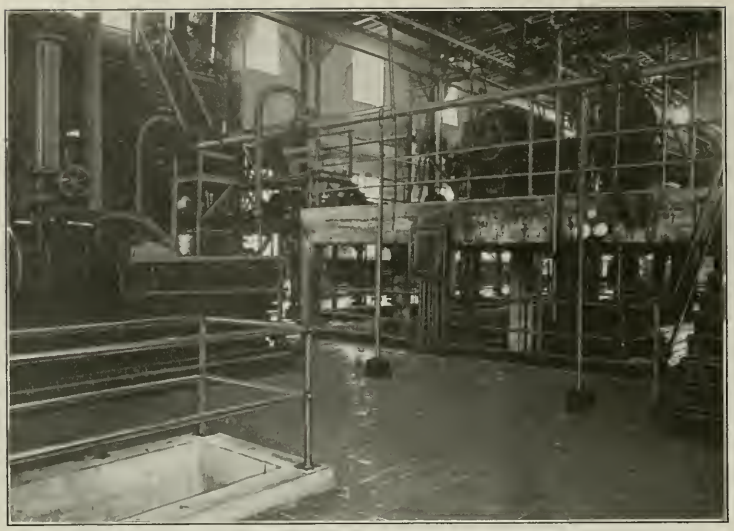
The transition to the rhombohedral form takes place at 84.2 deg. C. This change is abrupt, not showing a lag as in the previous case from 31 to 33 degrees; furthermore, the transition is not indicated by a distinct change in the solubility curve slope[4] as is shown at 32 degrees in the ammonium-nitrate curve of Fig. 1. When the salt is heated above its melting point, 169 deg. C., and cooled rapidly to atmospheric temperature, it passes directly to the needle phase showing no indication of the existence of or transition through the

CRUDE SALTS UNLOADING SHED AND STORAGE HOUSES

[4] W. Müller and P. Kaufmann, Zeitschr. physikal. Chem. 42,497. 1903.



VACUUM FILTRATION DEPARTMENT—ROTARY FILTERS ON PLATFORMS

intermediate phases. The transition at 84 deg. C. is accompanied by a slight contraction in volume and an absorption of heat, the density becoming 1.69 and the latent heat amounting to 5.33 calories per gram. The rhombohedral and alpha-rhombic states of ammonium nitrate with their accompanying physical properties are very important in the manufacture of the explosive amatol (80 per cent NH_4NO_3, 20 per cent TNT). The latent heat of 4-grams of ammonium nitrate is 21.53, while the latent heat of fusion of trinitrotoluene is slightly less, 21.4 calories. Direct application is found for these balanced latent heats in shell loading, the amatol being heated to above 84 deg. C., and because of its reserve in latent heat of transition the temperature of the mass does not cool to below 84 deg. and during the lag period of transition the amatol remains in a plastic condition[5] long enough to be loaded into the shell. The fine powdery alpha phase prevents segregation and assures a disseminated and thorough mix with the trinitrotoluol, producing a homogeneous amatol. When heated through 125 deg. C. the cubic system appears, the fine particles of which cling together in an almost collodial glue-like mass. This phase is one to be strictly avoided in ammunition work and prohibits the use of steam coils in contact with the salt. One per cent of water will lower the melting point of the salt from 169 to 159 deg. C., while 20 per cent of sodium nitrate with the salt gives a product melting at 120 deg. C. Thus it will be seen that in the presence of these materials, low temperature molten salts fusions are characteristic. Ammonium sulphate usually contains fixed coal-tar bases such as pyridene as well as from 1 to ½ per cent free sulphuric acid. The organic base is an undesirable impurity in amatol and the acid augments the very corrosive action of the concentrated nitrate salts on the equipment. Therefore sufficient soda ash to give a slight alkaline reaction is added so that both the pyridene is free to be volatized during the heating in the digestors and the liquor has as weak an acidic action as is possible with such a weak base as ammonium. No average analysis of Chilean saltpeter can represent the commercial conditions found in practice, for the caliche beds vary among themselves considerably as well as the methods of leaching them and crystallizing the more or less refined salts. The principal sodium salt impurities are chlorides, sulphates, borates and iodides. Potassium is the most important as well as variable foreign base present, good caliche earth often analyzing from 25 to 30 per cent $NaNO_3$ and from 3 to 5 and even 10 per cent KNO_3, with a result that extracted salts are found with minimums around 2 per cent KNO_3 and maximums up to 8. Ordinarily the percentage of sodium nitrate in Chilean saltpeter is in the lower nineties. Before the crude saltpeter can be used in the double decomposition process, it

CARRIER AIR CONDITIONING DEPARTMENT—COMPRESSORS AND COOLERS

must be thoroughly refined so as to prevent as far as possible the accumulation of foreign salts in the nucleus solution and especially remove the potassium salts, which have the property of crystallizing out with the needle ammonium nitrate, forming a highly undesirable impurity in amatol. Any alkaline earths that may be present will be precipitated as carbonates by the initial addition of soda ash and will pass out of the nucleus solution at the filters with the anhydrous sodium sulphate precipitate and other foreign solids. The halogen impurities are of minor importance, and so do not seriously affect the reaction. Next to potassium, the most trouble was found in keeping the solution cleared from pieces of bags, cordage, etc., which clogged the pump inlets.

Organization of Plant

The Atlas Powder Co. acted as agent for the Ordnance Department and installed an experimental plant where the details regarding apparatus, capacities and design ratios for carrying out the process were determined as well as possible. This was of prime importance in securing and training an experienced staff during the period in which the plant was being constructed so that no time would be lost in starting the works as soon as completed.

The process was operated continuously in three 8-hour shifts. A total of one hundred executives and technical men and 1800 mechanics and laborers were required in the operation. Mr. Frank S. Pollock, plant manager, was in charge of manufacture and plant. Among the personnel, the following should be mentioned:

Major A. S. Sinclair, contracting officer, U. S. O. D.
Mr. E. E. Bard, assistant plant manager.
Mr. J. T. Power, in charge of construction.
Dr. Guy C. Given, chemical research.
Dr. Frederick Bonnet, chief chemist.

Power and Water Plant

The Fred T. Ley Co. of Springfield, Mass., built the entire plant and are to be commended for their speedy and excellent construction, especially of the twelve 830-hp. boiler power plant in the record breaking speed of 64 days. A 10,000-hp. B. & W. Stirling boiler installation equipped with Westinghouse electric stokers, 4500-ton capacity overhead coal bunkers, two 210-ft. hollow tile stacks, steel derricks with clamshell coal buckets and three 1000-kw. condensing turbo alternators, together with forty miles of steam and water pipe lines from 30-in. diameter down make a million-dollar job alone, and in ordinary times might be considered as a large undertaking. However, compared to the expenditures for the entire plant, the power department cost about 7 per cent.

Water was obtained from the Susquehanna River by a main pump house having a capacity of 30,000,000 gal. per 24 hours. A special sluiceway had to be sheet piled and excavated to deep water so as to obtain a clear flow to the pump. Ninety-five per cent of the water was used direct for cooling purposes in the plant and was exhausted into Chesapeake Bay through the sewerage system, while the remaining million gallons was refined by the usual alum filtration and liquid chlorine process and used in supplying the boilers and potable mains throughout the plant and village. About 80 per cent of the boiler steam was consumed directly in heating the digestors and evaporators and 10 per cent each in the water pumping station and in the electric power house, which supplied the lighting system and the motors throughout the plant used in driving pumps, agitators, belt and bucket conveyors, compressors, fans, rotary filters, etc.

Chemical Plant Layout

The chemical plant consists of two similar independent units of equal capacity, with the soda purification, distilled water and liquor storage, centrifugal and finished product houses in common. The solid materials were transported on belt conveyors through tunnels. Stationary and portable bucket conveyors were used for elevating the materials to the crude storage piles and charging the belts and weighing machines. The buildings were constructed of hollow tile and concrete so as to reduce fire risks and furnish heat insulation for the process. As ammonium nitrate has a disintegrating action on concrete, all floors likely to come in contact with this material are tiled, especially those in the liquor filtering and pumping departments. The buildings were roofed with 3-ply everlastic laid on a yellow pine deck attached to steel beams.

A standard gage railroad track makes a complete loop around the plant, double tracks passing on both sides of the raw material stores and under the finished product bins, allowing ample unloading and loading space, and, with the sidings, giving a 5½-mile yard within the works.

The production capacity of finished ammonium nitrate of 94 per cent purity and 2 per cent moisture content was close to 300 long tons per 24 hours. This required the handling of 350 tons of sodium nitrate, 300 tons ammonium sulphate and 4½ tons of soda ash per day.

Crude Storage Houses

As one enters the gates, the odd ten-sided structures conforming to the outlines of piled materials, with incline conveyors climbing up their pyramidal roofs, first excite one's curiosity. The two largest, with "Crude Soda" painted on their concrete walls between the bracings, hold around 1000 carloads of saltpeter when full. The smaller octagon-shaped stores marked "Sulphate" have much less capacity because ammonia is a domestic material and need not be carried in such large stocks. The storage spaces for soda ash and refined soda are also of modest size and for evident reasons, the latter being a governor on the soda refinery and carrying sufficient supplies to tide over minor interruptions in the previous operations.

The empty nitrate sacks are sent to the bag washing department, where they are mechanically freed from as much soda as possible in a tumbling reel and then conveyed counter-currently through a simple rectangular box washer, passed through a wringer and dried in a hurricane Philadelphia drying machine. The feed water is so adjusted as to furnish a saturated solution of nitrate which is piped to the saltpeter purification department storage liquor tank.

The crude sodium nitrate crystals were fed directly into a Dorr six-deck washing classifier set at a 2½-in. pitch, which agitated and conveyed the crystals up through the down-coming saturated nitrate solution from the bag washing department. A sufficient extraction of the potash and chloride content was obtained with the exhausted wash liquor carrying about 34 per cent $NaNO_3$ and 28 per cent KNO_3. While quite successful in the operation, two important difficulties were experienced, of which the accumulation of fines at the base of the classifier was very serious, overloading the mechanical parts of the machine and making it necessary to reinforce points that were over-stressed. This was counteracted by discharging the fines at the base at intervals. The other difficulty was to free the crystals from sufficient mother liquor to break their coherence. This was accomplished by riveting a three-foot apron of eighty-mesh punched sheet iron at the crystal discharge end and extending the rake sufficiently to convey the material over the screen. It was intended to apply suction and thus pull the adhering wash liquor off. An Oliver sand filter was used successfully during the operation of the plant for preparing the crystals for conveying to and storage in the "Pure Soda" building.

The wash liquor was concentrated in two large Buflovak vacuum evaporators and the several salts crystallized in fractions. This department was being developed by the research department and had not reached a permanent manufacturing basis, but undoubtedly pure potash salts would have ultimately been made on a large scale[6].

Digestion Departments

The two batteries of 900-cu.ft. Buflokast iron horizontal cylindrical digestors are housed in separate buildings between which the mother liquor storage tank house intervenes. Each battery was installed with eight digestors, the combined contents of which was 450 tons of solution per unit, the flow of which was obtained by an eighteen-inch drop in level between digestors. During the operation it was found that numbers five, six and seven could be dispensed with. The digestors were connected by both overflow open conductors and underfeed pipes. The materials were added continuously to number one at a normal rate of 500 pounds per minute through automatic weighing machines. The salts are thoroughly agitated with the hot nucleus solution. Steam is blown in directly to obtain rapid fusion. Samples are taken constantly and the end of the reaction is determined by the absence of sulphate in the sublimate obtained from volatilized ammonia salt vapors upon fusing the dehydrated liquor.

MOTHER LIQUOR CONCENTRATION DEPARTMENT NO. 1—VACUUM EVAPORATOR AND MIXING TANKS

[6]Process for Separating $NaNO_3$-KNO_3, Given and Barteaux, U. S. P. 1,294,788.

Great care must be taken in preventing the pipe lines from becoming frozen or blocked with solidified salts, and when a pump is stopped for repairs the line must be blown with air or steam immediately and flushed with hot water to remove any accumulated solid crusts. The greatest trouble experienced in the operation of the plant was with the pumping equipment. The hot concentrated nitrate salts probably enjoy the record for corrosive efficiency, often demonstrating this by putting a new pump out of business in a few hours of use. The pump packing found most successful was asbestos graphited braid which had been slightly lubricated with soap, which probably reacted with the liquor, giving a modification of the so-called nitrated-oil rubber. As more or less bagging, rags and rubbish seemed to get into the liquor in spite of many precautions, it was not thought safe to use silicon iron, which is very brittle and apt to break when jammed suddenly. However, a screen trap could have supplied a cure for this trouble and undoubtedly chemical iron ware would have been a boon to the pump man.

The liquor pumps did not enjoy a monopoly of the pump troubles, for the vacuum apparatus pulled a fine liquor spray into its headers which solidified and acted most effectively, making frequent clean-outs necessary which were humorously referred to by the men with some thought of their rival at Muscle Shoals as their "Air Nitrate Plant." This trouble was eventually overcome by greatly enlarging the size of the exhaust mains with a consequent decrease in the gas velocity to a point where no spray was carried to the cold zones.

The liquor was filtered with Oliver continuous vacuum rotary filters. Extra ports were added so as better to distribute the suction and clearing steam back pressure. Cotton, monel metal and wool fabric were used, the former being immediately destroyed, the second lasting about two weeks at a cost of $400 per filter and the third giving the cheapest service, lasting one week at a cost of $67 per machine. A quarter-inch mesh aluminium-wire screen was applied to the cylinder, the wool placed over it and wound spirally with heavy monel wire, six revolutions to the inch. Both the aluminium and monel metal had given permanent service without replacement. As about twenty Olivers were in operation, the filter fabric was an important cost. The support received by the wool determined its life, for as soon as bulges were formed between the monel spiral, the friction of the scraper soon wore a hole through the fabric and made its immediate removal necessary. The anhydrous sodium sulphate crystals removed from the filters were mixed with distilled water, refiltered and dumped to the waste belt conveyor. As the hydrous phases begin to form at temperatures below 33 deg. C., considerable trouble was experienced with rebuilding crystals, which grew tenaciously to the idler rolls, the belt and everything with which they came in contact, somewhat after the manner of freezing water. While the most excellent service was obtained from the nitrate, sulphate and carbonate conveyor systems in the other parts of the operation, dump cars or even hydraulic conveying perhaps would have been more suited to this department. At the end of November, the sulphate dump contained about five hundred carloads of salt, which carried a small content of nitrates. Among the illustrations a view is given of the waste conveyor and trestel incline, which is designed so that the salt coming from the main cross-tunnel belt conveyor serving the two digestor liquor filter departments could be either dumped into trucks or carried to the storage pile.

Upon consulting the cycle graphically charted in Fig. 1, it will be seen that the filtrate, if simply cooled to 20 deg. C., would be supersaturated with all three salts. In European practice, several methods of separation have been worked. Roth[7] claims to get good yields by fractional fusions of the anhydrous salts. Lennox[8] sublimates under vacuum and Craig[9] carries over the ammonium nitrate vapor with ammonium gas. As there is a wide variation in solubilities, fractional crystallization commends itself. However, where efficient vacuum evaporating apparatus is used, the best method of refining is believed to be had by simply adding sufficient water to the liquor to bring the sodium nitrate down to 3b and the sulphate to 3c as shown in Fig. 1. The cycle shown illustrates the character of the process outlined, but does not represent the actual practice. Since

[7]D. R. Pat. 48,705, 53,364 and 55,155.

CRYSTAL DRYING DEPARTMENT—FOUR BATTERIES OF TOLHURST CENTRIFUGALS

the initial hydration of anhydrous sodium sulphate produces the heptahydrate[10] the point 3c will be located between the hepta and deca curves. However, dilution is always based on the ordinate 3b — 0b, since the sodium nitrate solubility increases with higher temperature and the sulphate decreases. The NO_3 ion of the very soluble ammonium nitrate depresses the solubility of the saltpeter to 0b, while the Na ion of the nitrate depresses the sulphate down to 0c. In determining the required amount of water for dilution, crystal tests were run for the sodium salts at the mixing tank, which were continuous, the ratio of the two liquid feeds being gaged by calibrated Pelton nozzle orifices.[11]

Crystallization Departments

The crystallizing building of each of the plant units was divided into four sections, each of which was equipped with fifteen rows of eight-deck 40-cu.ft. iron pans. As about 120 pans were filled per hour, all the parts took care of the production of an 8-hr. shift. In order to prevent the temperature from falling below 20 deg. C., where the sodium salts would be crystallized out, and yet obtain a maximum yield of ammonium nitrate needle crystals, it was necessary to install an air conditioning plant with each of the pan rooms. Four Carrier automatic temperature and humidity regulating systems were installed, where the crystallization was carried out under controlled conditions at 20 deg. C. Full treatment will be given to this operation in an early issue.

When the ammonium nitrate content of the mother liquor in the crystal pans is sufficiently low, the plug is pulled and the liquor allowed to drain off into a pipe line leading to the mother liquor storage building, located between the digestor buildings, where it is pumped into one of the sixteen 3000-cu.ft. tanks located there. Three 900-cu.ft. Buflovak vacuum evaporators are in each digestor building, by which the spent mother liquor is concentrated to nucleus liquor concentration to be returned to the next cycle. At the same time, the condensed vapors furnish distilled water for subsequent diluting and washing.

The drained crystals are raked from the pans to a belt conveyor, which charges them into Tolhurst centrifugals. The moisture content is quickly reduced to the 3 per cent maximum and the finished product discharged from the bottom to a belt conveyor, which carries it to elevated storage bins to be loaded into box cars by gravity upon shipment. Thirty-two centrifugals are used, eight to the crystallizing room, or one to each fifteen pans.

Due to the sudden cessation of the manufacture of explosives, this plant was closed after almost as brief an operating period as it took to construct it. However, it met in excess all the demands made upon it and is a far better investment than commonly can be made by the War Department. It cost less than half the usual expenditure for a battleship and is capable of abundantly rendering more than its equitable share in the national business of war. Furthermore, should war go out of style, this plant can be readily converted to peace-time pursuits.

[10]Loewel, Ann. Chem. Phys. 49, p. 50, 1875.
[11]The formula is: $Q = 99d^{1.93}H$, Q = quantity lb., d = diameter orifice, H = heat in feet

Reclaiming Steel Works and Industrial Wastes

By Francis Hall

FUNDAMENTALLY wastes may be divided into two classes—waste of materials and waste of effort. In what follows, material wastes only are to be treated.

The principle of saving of wastes is almost as old as the hills. It was dwelt upon at length in the Holy Scriptures and was practiced in ancient times. No doubt, owing to the greater simplicity of life and industry in earlier times, more stress was laid upon savings and the control of wastes was easier. In any event, the salvage and control of wastes are anything but a simple matter at present, whether they be household, governmental or industrial.

As the volume of business and the magnitude of individual undertakings have increased, the facilities and the means of every kind have increased in size and complexity. Higher grade products and higher efficiency of production have frequently increased rather than lessened the amount of material classified as primary wastes. At all times, in America particularly, the general slogan has been "production," "get out the product." With works' executives, superintendents, foremen and leaders all constantly absorbed in getting greater production, it is not strange that the humble but highly profitable task of utilizing any accruing wastes to the same degree of efficiency should be neglected.

Importance of Saving in Peace Time

Fundamentally, America is not a saving country. As practiced by the French, saving and reclaiming almost every available bit of waste, as well as money, are generally unknown here. If saving is important in war times as a national necessity, it is doubly important in peace in order to preserve the national ease, comfort and standard of living at times when the lowest-priced good products command the market. In steel, munition, engineering, chemical, mining, and in general in all other industries, the fundamental ability of a plant to get the most out of its materials is largely dependent upon a personal equation—not of its executives, but of its workmen, down to the lowest rank. Most executives realize this, but somehow it has seemed difficult to compass effective salvage of materials when men and leaders devote unstintedly their time and effort to attaining a splendid volume of production. Moreover, neither the executive, foremen nor workmen have, as a rule, any clear personal idea of what it means to save their own, much less save somebody else's (their employer's) waste material. It is all waste or junk to them, fit for the dump or ash heap and therefore not worth bothering their heads about, so long as it is gotten out of the way promptly.

Most Americans are familiar with the slogan of the great packing industry, who claim to be saving and utilizing the entire pig, beyond the squeal. This seems literally true, and in fact is forcibly brought out by the recently issued report of one of the large packing concerns showing their entire yearly profit to have been made by utilizing to the last degree the by-products formerly wasted.

It is unfortunate that the same may not be said of the majority of other American industries. The surest sign of the lack of waste-salvage is the scrap pile, and this applies, paradoxically though it may seem, to the steel industry. For while scrap enters largely into the manufacture of steel, the character and makeup of the scrap stock-piles of a steel plant provide a sure indication of the degree of wastage occurring in the department or outside industry where it originated.

The most complicated problem of salvage so far undertaken is presented by the modern fully-integrated steel works with production from mine and scrap to finished product, be it principally armor plate, armor piercing projectile, shrapnel, high powered ordnance, turbine elements, car wheels, forgings, shafting, sheet, ships, bars, plates, rolls—all finished or green materials. Why this is true may be easily explained when it is understood that the large combined steel and ordnance works require nearly every branch of modern engineering and technical skill, together with the accompanying vast flow of both raw and finished material and innumerable kinds and classes of standard and special equipment and tools. In addition to the primary or producing departments, such as blast furnace, open-hearth, blooming mills, rolling mills, bar mills, sheet mills, rail mills, tire mills, steel foundry, forge shops, press plants, annealing plants, oil tempering plant, armor tempering plant, projectile plant and ordnance plant, consider that there may be necessary from 30 to 75 separate and distinct auxiliary departmental organizations, each demanding a constant flow of more or less specialized material and equipment and a consequently inevitable outgo of used, partly used, good, new, worthless and indifferent scrap, waste material and equipment.

Money in the Junk Pile

Consider this and the multitude of real facts about such a plant one can find by tedious, persevering and painstaking watchfulness and personal investigation, and the most recalcitrant doubter will become convinced that there must be something in that specialized industry that maintains and waxes rich a junk man in every little town. He will find that rubber is rubber, burlap is burlap, leather is leather, and lumber, asbestos, pipe fittings, electrical parts, pulleys, blanks, gears, bushings and so on almost to infinity are each what they are —scrap, good or fair, and each item capable of yielding dollars like finding the money by a simple common-sense treatment. He will also realize that by reducing the handling of current waste material by regularly and systematically collecting, disposing and utilizing it at some other place in the works as far as possible he can cut his costs of operation to where a low-priced contract can be taken now and then that will "keep the wheels rolling." He will find that those short (but otherwise good) bars, tubes, plates, rolls, castings, forgings, ingots, tool steel or merchant bar are just what some engineering, shipbuilding, railroad, electrical or machine works may be dying to get and would pay a round price for—a price that will make melting-up and thereby destroying the real value look more than criminal, besides adding a nice fat look to the profit side of the balance sheet.

He will, at length, learn the simple maxim that "a penny saved is a penny earned" just the same in a steel plant or aircraft or metallurgical works as in his own personal affairs.

It is not only patriotic, it is common sense, to save and utilize, to reclaim all available material of every kind, to dispose of it regularly and profitably, to eliminate entirely in America for all time the costly hideous miscellaneous scrap piles. It is the highest type of war preparedness or industrial peace preparedness that spells the real quality of invincibility. In extenuation of the lamentable condition as to nation-wide wastes in which the United States has by this war discovered herself may be advanced the freedom from real want and the universal easy-living conditions so long continued as to dull the usual sense of caution.

It may be safely said that no modern specialist is required to be as versatile and widely technically informed as in the new vocation of industrial reclamation engineering. Initiative, imagination, decision, resource and ingenuity must be available to the last degree in making the big and profitable undertaking such work will become in almost any American works. The general principles involved in the handling of scrap and wastes profitably on a large scale and in the variety found in a large steel or industrial plant are simple enough. Getting the business going promptly and in a way to pay for itself from the start is a task which will take all any normal being has in him.

Philadelphia, Penn.

Commission to Settle Losses on War Minerals

Former Senator J. F. Shafroth of Colorado, Philip N. Moore of St. Louis, Mo., and former Representative M. D. Foster of Illinois have been appointed by Secretary of the Interior Lane as members of the commission that will have charge of the payment of the losses incurred by mining men in the production of manganese, chrome, pyrites and tungsten for war purposes.

During the war the Interior Department, the Emergency Fleet Corporation and the War Industries, War Trade and Shipping Boards insistently urged the mining men to produce these materials to supply the urgent needs of the nation for war purposes. When the armistice came, these mineral producers, as a result of their response to the demands of the Government, had on hand ready for delivery quantities of these materials, for which there was no peace-time market.

Congress set aside $8,500,000 to meet claims for these losses, which must be filed within three months after the passage of the act. The law provides that the claims must have been incurred between April 6, 1917, when the United States went to war, and Nov. 12, 1918, when the armistice was signed. The Secretary of the Interior is charged in the act with taking into consideration and charging to the claimant the market value of the minerals on hand Nov. 12, 1918, and also the salvage or usable value of the machinery that was installed to produce these war minerals.

Mr. Moore is a former president of the American Institute of Mining Engineers and a well known engineer.

Mr. Shafroth was a member of the Senate Committee on Mines and Mining of the Sixty-fifth Congress and Mr. Foster was chairman of the House Committee on Mines and Mining.

Practical Considerations in Ammonia Leaching of Copper-Bearing Ores

Description of Plant Installation and Operation—Leaching Tanks: Plate Joinings, Filters and Inlets—Piping and Pumps—Evaporators—Details of Operation: Charging and Extracting Ore, Chemical Control—Cost of Leaching: Labor, Power and Ammonia

By LAWRENCE EDDY
Formerly Mill Superintendent, Kennecott Copper Corp., Kennecott, Alaska

THE engineering profession is already acquainted with the successful extraction of copper from its ores by an ammoniacal solution. In the year just past a number of improvements, mostly of a mechanical nature, have been worked out at the plant of the Kennecott Copper Corporation at Kennecott, Alaska. These developments are presented here, with some other points of interest to practical metallurgists.

The leaching plant at Kennecott is designed to treat the tailings from a "wet" concentrating mill, and has handled 450 tons of mill tailings per 24 hours, average of one month's run. The maximum capacity, however, with the equipment as herein described, is over 600 tons per day. Scarcity of ammonia and other abnormal conditions have reduced the tonnage to the lower figure.

The ore as mined contains copper in the form of sulphides, mostly chalcocite with some covellite, and also oxidized copper in the form of the carbonate malachite. The gangue is limestone. There is no native copper metal present. Treatment of the ore on concentrating jigs and tables gives a very good recovery of the heavy sulphides, but the malachite is inclined to be porous and flaky, and is of nearly the same specific gravity as the limestone, hence 40 per cent of this copper escapes from the jigs into their tailings. The ordinary acid leach is not suitable to recover this copper because it also attacks the limestone. Flotation would entail more grinding and the dubious problem of sulphidizing.

Under these circumstances ammonia leaching was adopted, and the process has now been cheapened so as to permit its application to a wide range of ores. Ammonia will not recover any gold or silver values, or any copper sulphides unless roasting is resorted to. With oxidized copper having the general form $CuCO_3 \cdot Cu(OH)_2$ a dark blue solution is formed which on heating gives off NH_3 vapor, CO_2 gas, and deposits a heavy black powder consisting mostly of CuO. The writer is not prepared to give the chemical formula of the blue copper-ammonia solution; he believes it to be a mixture of cuprous and cupric combinations, and that the proportions differ under different conditions. Table I shows the character of the mill tailings as they reach the leaching plant. Copper sulphides are also present in addition to the oxidized minerals to the extent of 0.20 per cent, but, being inactive in the leach, they are considered as part of the gangue. Roasting would not pay as so small a quantity of sulphides would be recovered.

Brief Comment on Flow Diagram

Item 1. Mill tailings are leached just as they come from the jigs and tables without any further crushing. They must be deslimed, however, because the slimes have the bad effect of cementing the ore together in the leaching tanks, forming a hard mass that is not easily penetrated by the leaching solution or the steam wash. It is also much harder to excavate the leached tails unless they are cleaned of material finer than 200 mesh. Desliming apparatus consists of two esperanzas 5 ft. wide and 30 ft. long. One only is in use at a time, the other being a spare. Table II shows the character of the deslimed ore. Most of the minus 200 mesh material has been removed, but all the fine sands are left in the ore. At present these slimes are run to waste, pending further developments in a process for their treatment. An extraction of 80 per cent can be obtained from the deslimed ore. Screen tests show that the best results are had with finer sizes, plus 60 mesh material giving the best extraction. However, the recovery from the coarser sizes does not drop enough to warrant putting

in a crushing plant, especially since it would entail a still greater slime loss.

Item 2. A 300-ton storage bin is installed to permit of short shut-downs in either mill or leaching plant without inconvenience to the other.

Item 3. The ore is fed from bin gate to an elevator by a 32-in. "apron" feeder; it is elevated to the top of leaching tanks and conveyed by a chain-scraper to the charging doors on the tops of the leaching tanks, into which it drops by gravity. The resulting cone of ore is leveled off inside the tanks by revolving the excavator mechanism backward, and by hand shoveling. Rate of charging tanks is about 600 tons per 24 hours.

Item 4. It is to be understood that processes 4 to 10 are applied to the ore without transferring it from one tank to another. The order in which each step of the process occurs is from top to bottom of the chart. There are eight steel leaching tanks constructed as shown in Fig. 2 which are charged and put through these proc-

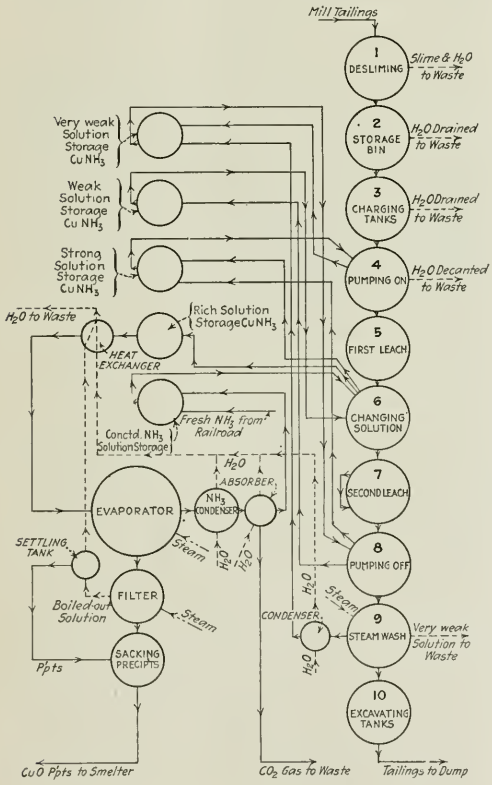

FIG. 1. FLOW DIAGRAM

esses in rotation. Process 4 requires about eight hours, during which the lixivant is pumped into the bottom of the tank and rises up through it. This displaces the moisture contained in the ore upward to the top of the tank, which is still approximately 5 per cent of the dry weight. Part of this can be decanted off the top of the charge to waste as it rises above the incoming ammonia solution, while part becomes mixed with ammonia and is decanted into the weak-solution tank. The remainder is left in the ore, where it dilutes the leaching solution.

Item 5. The ammonia solution is allowed to stand on the ore for 12 hours, without any agitation.

Item 6. A portion of the first leaching solution, approximately saturated with copper, is pumped from the bottom of the leaching tank; at the same time an equal volume of concentrated ammonia, together with some weak copper-ammonia solution, is pumped on the top of the charge.

Item 7. For 30 hours the leaching solution is circulated through the charge by a centrifugal pump which draws the solution from the bottom and discharges it on the top of the charge.

Item 8. Having dissolved all the copper that will go into solution in 30 hours, the leach is now drawn off from the bottom of the charge and transferred to the storage tank for strong copper-ammonia solution; at the same time 20 or 30 tons of weak solution or "wash" are pumped to the top of the charge and allowed to trickle down through it so as to wash out the strong leaching solution.

Item 9. Steam is turned into the top of the tank for about 12 hours, so that it heats the entire charge. This vaporizes any ammonia left in the ore, the weak ammonia vapor passing out of the tank through the drain pipes in the bottom and being recovered in a special condenser, from which it is transferred to the weak-solution storage tank. When the ammonia content of this condensate has fallen to 0.45 per cent, the wash is considered finished and the steam turned off.

Item 10. The doors in the bottom of the tank are opened, which allows the tailings to run out on a conveyor belt and thence to the tailings dump. Less than half of the charge runs out by gravity; the rest is excavated by means of a number of scrapers that revolve about a central shaft and are fed down through the tank by means of an automatic feed screw. Some of the tanks are not yet equipped with this excavating mechanism, and in them a light "slip scraper" is used, guided by hand and pulled by a small hoisting cable working through the top door of the tank. This device is unsatisfactory because a great deal of time and valuable cooling water must be expended before a man can get into the tank to guide the slip. Formerly all tanks were excavated by hand shoveling at a cost of about 11c. per ton.

The Leaching Tanks

More particular comment will now be made on the special appliances used. Fig. 2 is a sectional view of one of the leaching tanks, of which there are eight. The incoming ore was formerly distributed over the tank by means of a rotary feeder in order to prevent segregation of the finer particles. Recently this has been found unnecessary and now the ore is simply dumped into the tank through one of the top doors and leveled off. This method of charging gives a light porous bed of ore which is easily penetrated by the solutions. It is advisable to level off each charge carefully to exactly the same depth so that identical volumes of leaching solution will always just submerge the ore. Otherwise costly irregularities in the operation of the plant will ensue, and the capacity of the storage tanks will be taxed by a large amount of idle solution.

While the tank is being charged and during the interval between charging and the application of the first leaching solution, a considerable quantity of water seeps

out of the ore and is allowed to escape by unscrewing drain plugs in the bottom of the tank. If this water were left in the ore it would dilute the leaching solution, and eventually would have to be boiled out of the system in the evaporators at a considerable expense for steam. Therefore this drainage is important, and should be encouraged as much as possible by hurrying other processes to allow a maximum interval for drainage. Plugs are used here because no valve or cock has been found that will remain tight more than a few weeks. Where lines run from one tank to another a little leakage through the valve will cause no loss of solution, and an ordinary all-iron gate valve is perfectly satisfactory, but all pipe ends that lead from the system must be protected by plugs.

The tanks themselves are made of single-lap riveted steel plate about $\frac{5}{16}$ in. thick. It is well to construct the dome top with a short radius so as to furnish added strength against suction, since at times during the steam wash, a vacuum is induced, due to too rapid condensation of the steam, that will buckle a weak top with disastrous results. The same thing occurs when a careless operator pumps solution out of the tank without opening a relief valve on top of the tank. In opposite effect, too much steam builds up a pressure that will cause the flat bottom to bulge and leak badly at about 5-lb. gage. All these difficulties can be obviated by a good safety valve set for small differences both of pressure and vacuum. Such a device, made entirely of iron for ammonia service, has not been found on the market and must be made to order. Vapor pressures as mentioned above are all measured by a mercury manometer.

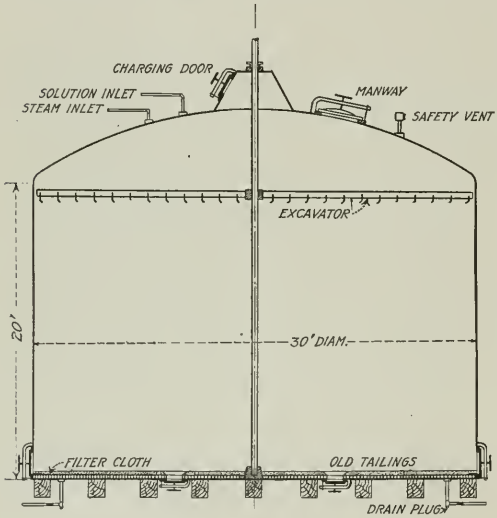

FIG. 2. SECTIONAL VIEW OF LEACHING TANK

Leaks in Tanks a Large Expense

Due to alternate heating and cooling, and to accidental deformations due to excessive pressures, these leaching tanks soon leak at the seams, especially around the bottom, where the pressure is greatest. Recaulking is only a temporary relief, and often leaks come at points of support or at other inaccessible places. These leaks are one of the largest sources of expense in the plant. Constant vigilance must be exercised to detect new leaks and if they are beyond remedy to arrange receptacles to catch as much of the solution as possible. One of the routine duties of the operator must be to collect and empty these drippings. A concrete floor has been placed under each tank to catch leaks, but it fails in its purpose because so much water gets into it in one way or another that any ammonia solution is diluted to a point where it does not pay to save it. The writer believes all this difficulty can be eliminated by electrically welding the tanks when they are first installed. It is doubted whether this would prove successful on tanks which have been long in service and whose seams are coated with silt and scale.

Gage glasses on leaching tanks are unnecessary. If used they must have all-iron fittings which are expensive and hard to get. One should guard against running up the cost of installation with such accessories, which may be convenient, but can be dispensed with.

Filters

The entire bottom of the leaching tank is covered with a filter bed adapted from cyanide practice with practically no change. One thickness of heavy duck makes a satisfactory filter and can be purchased already sewed and cut to fit the tank. To protect this cloth from mechanical wear a cover of "cocoa matting" is placed over it. Both cloth and cover are cut 6 to 10 in. larger than the bottom of the tank, and this flap is calked into a recess left between the tank wall and the wooden grid which supports the cloth. A piece of manila rope calked into the trough holds the cloth firmly in place, and as an added precaution strips of wood are nailed around the circumference on top of the filter and its cover. The grid to support the cloth can be made of fir strips 2 in. high and 1 in. wide nailed together so as to leave a 1-in. space between each two strips. They must be notched on the under side to permit free drainage of the filtrate along the bottom of the tank to the outlets. They must not be fastened with metal clips or strips, because these soon disintegrate in the leaching solution, and lodge in valve seats, pump impellers and other unfortunate places all over the system. After from 18 to 24 months' service the grid becomes soft and pulpy and must be replaced. The life of a filter can be greatly extended by always leaving 6 in. of tailings on top of it when excavating the tank. Under such circumstances filter cloths and covers ought to last 12 months. This natural filter bed must be changed every few months when it becomes saturated with slime. This bed forms a dead space in the tank that will not impart any copper to the leaching solution which occupies it; hence the first few tons of solution drawn off the tank after the first leaching period will be low in copper, and should be run into the weak solution tank to avoid diluting the main part of the rich solution.

Doors

All doors and frames are of cast steel, with finished surfaces where they meet. They can be forced shut on a gasket by means of a screw clamp. The most satisfactory cheap gasket for everyday use on 12 x 12-in. and 12 x 16-in. doors consists of several thicknesses of building paper well smeared with some sticky substance such as paint—cold-water paint is good. This gasket can be used but once. Sheet rubber packing makes a

better but much more expensive gasket that can be used several times. Asbestos sheet and woven packing is yet more expensive and no better. Cotton wicking is always kept for emergencies; improperly packed doors in the bottom of the tank cannot be readjusted after the tank is full, but their leaks can be mitigated by calking with a bit of wicking around the outside.

Piping and Pumps

Under some conditions the ammonia solution has a chemical action on iron. A hot solution containing a little copper will corrode the iron walls of a pipe to such an extent that the pipe is eaten entirely away at the threaded connection after a few months, and has to be renewed. Metallic copper is left behind, and presumably the iron goes off as a hydroxide. After more than two years of continual service the leaching tanks, however, do not show any evidence of such action; it is thought that the solution has to be in rapid motion,

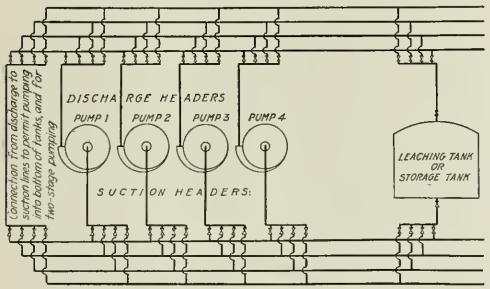

FIG. 3. PIPE AND PUMP DIAGRAM

as in flowing through a pipe, in order to promote corrosion.

It is possible to transfer all ammonia solutions needed in this process with six pumps. There are also a number of pumps required to handle cooling water for the condensers, water for use in excavating the leaching tanks, and other uses determined by local conditions. It is good practice to have not more than two sizes of pumps, make these a standard and have all pumps, both water and solution, in either one or the other of these sizes and of identical make and construction. This means that all-iron ammonia pumps will be used on ordinary water service, but the saving in the initial outlay for spare parts alone will cover the additional cost of the pump. When it comes to piping, a great saving in the money tied up in the warehouse can be effected by installing not more than two different sizes of pipe. For all ordinary work 2-in. piping is ample, both for suction and discharge pipes. By arranging the pumps on interconnected headers, as shown in Fig. 3, it is possible at times to allow two suction lines to discharge into the same pump so as to give ample suction-pipe capacity.

The most satisfactory small size pump which has been tried out is a centrifugal pump direct-connected to an electric motor. Such a pump with a 5-hp. motor and inclosed type impeller will deliver 125 gal. per min. against a 50-ft. head. The inclosed impeller is more efficient than the open type, but must be carefully watched to remove bits of wood and ore that lodge there and cut down the capacity of the pump and of the whole plant. In installing a pump it should be carefully gone over, because manufacturers of "all-iron" pumps obstinately insist on fitting them out with brass petcocks, screws, etc., which must all be taken off before using.

Small reciprocating steam pumps are troublesome affairs to pack and oil, in comparison with centrifugals, and are not very economical unless their exhaust can be utilized. There is an excess of waste heat about a leaching plant as it is, so that ordinarily no use can be found for any such exhaust steam.

Air lifts, where the compressed air comes in contact with the solution, are not favored, because a certain amount of ammonia would be carried off with the exhaust air in the form of vapor. A steam injector might prove very feasible for the purpose of charging the rich solution into the evaporators, where the heating of the solution would be a desirable feature. An all-iron injector for this purpose has been under consideration for some time. At present the evaporators are charged by a 10-hp. 4-in. centrifugal pump, which is our large standard pump.

Filtrate From Evaporators Hard to Handle

The most difficult solution to handle is the filtrate from the evaporators, or "boiled-out solution," as it is called. It is hot and contains enough dissolved copper to act strongly on the iron valves and piping. Valve wedges and stems will be put out of commission after only a few weeks' service. There is also copper oxide present which has leaked through the filter cloths and is carried along in suspension. This acts like emery dust, quickly cutting the shaft and thrust-bearing surface of a pump. The most satisfactory method of handling this material has been to apply steam pressure to the filtering tanks, so as to force the liquid through the filter cloth and out to the settling tanks.

Operating a centrifugal pump is something of a fine art at best, and with ammonia solutions new symptoms develop which a novice would fail to diagnose. For instance, in pumping strong ammonia solution, the reduction of pressure in the suction pipe causes some ammonia to vaporize and spoil the priming of the pump. By placing an ammeter on the pump motor it is possible to locate many troubles accurately; it shows whether a gland is too tight, or so loose as to let air suck into the pump (a very common trouble); it detects a plugged pipe line or a valve accidentally left closed. By suitable switch connections one ammeter on the switchboard can be connected to any pump motor at will.

There will always be some leakage about the pump glands; solution pumps should therefore be placed in concrete basins which will save this drip and allow it to drain into a sump. A very important feature about saving these drippings is to prevent them from becoming so diluted with surface water that it will not pay to save them.

It is a great help in "breaking in" new operators to paint the various solution lines with distinctive colors. In fact, if the operator-elect paints these over himself so much the better; assignment to this duty in our plant has now come to mean that a man is "on deck" for an operator's job. Solution pipes should never be buried, but should be left out in the open for easy inspection and repair. Lines carrying hot solution will have to be frequently replaced, both pipe and valves, so a lavish use of unions is good economy.

As for valves, standard all-iron "clip" gate valves are very satisfactory and are standard practice at Kennecott. They usually cannot be relied upon to seat absolutely tight after a little wear. Plug cocks may be used, but in the 2-in. size are very hard to manipulate. Special ammonia valves and fittings, such as refrigerating plants use, are absolutely unnecessary and very expensive. A permanent pipe fitter's bench fitted out with vise, cutters, taps, dies, etc., is a very essential part of the plant.

The Evaporators

The evaporator is the real heart of the plant. It has a twofold purpose: first, to remove the dissolved copper from the system at the rate it enters into solution from the ore, so as to maintain the dissolved copper in a state of equilibrium; and secondly, to remove water from the system as fast as it is introduced from the moisture in the ore and from the steam that enters the system, so as to maintain the volume of solution nearly constant at all times. From the standpoint of economy it is very important to minimize the quantity of water entering the system so as to save steam in the evaporators; in other words, it is better to evaporate a small quantity of solution, rich in copper, than a large quantity of weak solution.

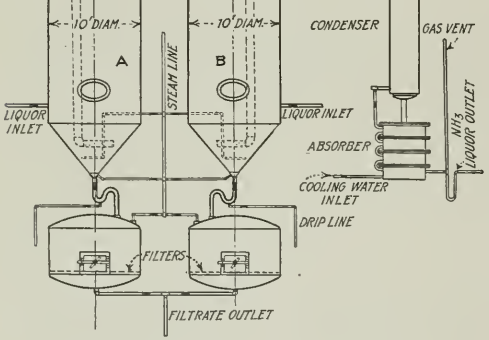

FIG. 4. DIAGRAM OF EVAPORATORS

Fig. 4 shows one of the duplicate units that have been evolved for our use after expensive large-scale experiments with various types of evaporators. While it will no doubt be further modified from time to time, this is by far the most satisfactory type put in operation up to the present.

The great difficulty in evaporator construction and operation has been the hard scale of copper oxide that tends to form over the interior surfaces both of the evaporator itself and also any steam coils or other heating surfaces. This renders the ordinary continuous distilling column with its complicated passages and trays absolutely useless after a few hours' operation. The higher the copper content the more this trouble is aggravated. However, scale will not be deposited on vertical surfaces, or on steep surfaces making an angle of 40 deg. or less with the vertical. Hence the evaporators of Fig. 4 have eliminated all this scale trouble and will run for months without cleaning. There are no heating surfaces to crust, because steam is admitted directly to the solution from a perforated pipe. It is also very essential to admit a jet of steam to the tip of the cone to keep the precipitated copper agitated—if allowed to settle it forms a dead space that would remain saturated with ammonia, and this ammonia would be lost when the precipitates are dumped into the filtering tank. Moreover, settled precipitates are liable to form a cake that will not readily pass through the discharge cock. It is sometimes necessary to start the discharge by means of a long poker worked through the vent in the top.

Details of Operation

At the start of operation both *A* and *B* are filled half-full of rich copper-ammonia solution. In practice this will test 5 per cent copper and 7.5 per cent ammonia. Steam is then turned into *A* only, and the valves in the vapor line set so that the resulting vapors will pass from *A* into the solution in *B*, and serve to heat *B*. The vapors from *B* are passed through the condenser, which reduces the ammonia and water to liquid form. This condensate, together with the noncondensible CO_2 gas, flows downward through the absorber or cooler, the gas bubbling through the liquid so as to scrub out all the ammonia. The liquid is then received in a storage tank and held ready for use again as a fresh leaching solution. The CO_2 escapes through another scrubber, where it is washed with water or a weak ammonia solution.

As the solutions in *A* and *B* commence to become warm the evolution of CO_2 becomes noticeable well before the boiling point is reached. No definite temperature can be set for this occurrence, because it depends on the composition of the solution, but usually the gas becomes noticeable at 130 deg. F., and very large volumes are given off before any ammonia vapor reaches the condenser. Between 160 and 170 deg. F. and under a pressure of 2 to 5 lb. gage in the evaporators, the solutions commence to boil and evolve ammonia vapor. Shortly after the ammonia starts, the evolution of CO_2 dies down and practically ceases. From this point to the end the evaporators show a bad foaming tendency, hence they are filled but half full at the start, and great caution is used in admitting the steam. A practiced operator, however, will easily control his evaporators so that only an occasional trace of copper solution will pass over into the condenser. The first ammonia vapors to go over into the condenser are, of course, very strong, but as the boiling continues they gradually become weaker, until at the end of the run they may be only 1 or 2 per cent ammonia, the rest being water. The average ammonia content of the condensate from a complete run will be about 16 per cent.

After five or six hours' boiling the ammonia content of the solution in *A* will have fallen to less than 5 per cent, and at this point copper begins to precipitate. It first comes down as a green copper carbonate, and would stay in this form unless steps were taken to prevent it. By raising the pressure in the evaporator to over 10-lb. gage, and by keeping the precipitates agitated with the jet of steam in the tip of the cone, the carbonate is changed to the black copper oxide. This latter is a more desirable shipping product, because it will contain more than 75 per cent copper, as against 60 per cent for the green carbonate. However, if the market should develop, a very good grade of copper carbonate could be produced.

Steam is kept on *A* until all but a trace of the copper has been precipitated and the ammonia content of the solution has been reduced to 0.03 per cent. This should require 10 to 12 hours. At the same time the solution in *B* will have been reduced to about 2.5 per cent ammonia, and the copper partly precipitated. Steam is now turned off *A*, the discharge cock opened, and the entire contents dumped into the filtering tank. Next a fresh charge of rich solution is pumped into *A*, steam turned on *B*, and the vapor valves reversed so that vapors from *B* pass into *A*, and from *A* into the condenser. *B* can now be boiled down to 0.03 per cent ammonia and dumped into its filter, and the procedure continued indefinitely.

While the evaporators are boiling, steam is turned into the filter tanks at about 15 lb. pressure, so as to force the "boiled-out" solution through the filter and leave the precipitated copper oxide on the cloth. The precipitate can be dried in this manner to less than 18 per cent moisture, in which condition it is sacked and shipped to the smelter. The filters consist of two layers of 8- to 10-oz. duck, protected by one cover of "hop cloth" and supported by a perforated metal screen. The cloths must be renewed about every four weeks, and the screens every four months. The filtrate should be passed through a series of settling tanks to save the small quantities of precipitate that always go through the cloth and the occasional large amount due to defective filters. The filtrate may also be passed over scrap iron, which will precipitate a small amount of cement copper from the last traces left in solution. If this is done, care must be taken not to allow the cement copper to cool while under the solution, because if it does the trace of ammonia present will redissolve it.

The discharge cocks on the evaporators are 4-in. all-iron asbestos-packed plug cocks, with easily replaceable packing. Every week the plug should be taken out, polished, well oiled, and a new packing inserted. Even with this care, at times the cocks will leak and allow rich solution to escape from the evaporators. However, such leakage may be trapped and saved as shown in Fig. 7.

The condensers are fitted with 2-in. boiler tubes of charcoal iron 12 ft. long, which have to be renewed about every eight months. At least 65 gal. per min. of cooling water must be available for each condenser, although they may not need this quantity all the time.

Plant Control

The services of one chemist are employed on routine analysis of solutions, and experimental work. Analyses of the ore are made in the regular assay office by the mine assayer.

The following simple method of testing solutions for copper and ammonia was worked out by Mr. E. B. Hunn, plant chemist: 10 cc. of solution to be tested is titrated against a standard cyanide solution until it is colorless; the amount of cyanide used indicates the per cent copper in the solution. Another 10 cc. is titrated against a standard H_2SO_4 solution, using methyl orange indicator; the acid reacts with both copper and ammonia until the solution is neutralized, at which end point it takes on a pale green color. From the quantity of acid used, and from the previously determined copper content of the solution, a specially prepared chart enables one to find the per cent of ammonia in the solution. These are the only determinations ordinarily needed to control the plant.

It is part of the operator's duties to sample every batch of solution which is pumped. He takes the samples from the discharge side of the pump through a special cock into a sample-bottle, labels it and leaves it in a rack for the chemist. There is often a wide variation in ammonia and copper content in standing solutions at different depths in the same tank. Due to this stratification it is necessary to take the sample in several equal parts uniformly spaced over the entire time of pumping. The operator also keeps a daily log sheet, on which are entered the time, quantity and disposition of every batch of solution pumped. Once daily he reads the gage glasses on every storage tank and enters this in the log sheet. Most of these storage tanks are 16 ft. in diameter by 20 ft. high, and the scale is calibrated to read in tons of 2000 lb. of solution. This unusual unit of liquid measure is very convenient as to size, and saves a great deal of work when figuring in connection with quantities of ore, which of course are expressed in tons.

It is to be noted that all these measurements, and the titrations for copper and ammonia, are really volumetric, and are accurate measures of weight only when the solution has a specific gravity of unity. This is seldom the case in practice, various solutions ranging from 1.06 to 0.97 gravity, so that for special purposes these differences must be taken into account.

Costs

To say that our leaching expense amounts to $1 per ton of ore treated is misleading. There are some very unusual conditions in Alaska; there is no standard method of keeping mining costs, and the cost of treatment is greater for rich ore than for lean ore. Therefore the following example has been worked out, using the same quantities of labor, steam and ammonia which

EXPENSE OF LEACHING 450 TONS OF CRUSHED AND DESLIMED MILL TAILINGS PER 24 HOURS

Copper (oxidized) content of ore leached..... 0.85 per cent
Copper (oxidized) content of ore tailings..... 0.17 per cent

Gross extraction is 13.6 lb. copper per ton leached. Of this about 1 per cent, or 0.1 lb., must be deducted as dissolved copper lost in the leaching process, leaving 13.5 lb. per ton to ship to the smelter. This is shipped in the form of copper oxide containing 75 per cent copper and 18 per cent of total weight as moisture (per cent copper figured on dry weight). Smelter deductions will amount to 0.2 lb., so that the net copper sold will come to 13.3 lb. per ton leached, or 5985 lb. per day.

Leaching Expense for		Total Per Day	Per Ton	Per Lb. Cu Sold
Direct Labor:				
1 Foreman at	$6 00	$6 00		
1 Chemist	5 00	5 00		
3 Shift bosses	4 50	13 50		
3 Operators	4 00	12 00		
9 Laborers	3 50	31 50		
1 Repair man	4 50	4 50		
Total		$72 50	$72.50	$0.161	$0.0121
Power and Lights:				
630 kw. at 2.5c. per kw. (1.4 kw. per ton)		15 75	.035	.0026
Ammonia:				
0.25 lb. per ton loss in leaching	$0 25			
0.02 lb. per lb. Cu loss in evaporators. 13.5 × 0.02	.26			
Total loss per ton	$0 51			
Cost, at $0.50 per lb. NH_3		114.75	.255	.0192
Steam:				
94 lb. per ton for steam wash	.94			
16 lb. per lb. Cu for evaporation 13.5 × 16	216			
Total steam per ton	310			
Cost at $0.001 per lb.		139 50	310	0234
Maintenance and Repairs: Includes cost of all maintenance of machinery and buildings, both materials and extra labor necessary		25 00	055	.0042
Operating Supplies: Sacks, oil and waste, packing, etc.		15 00	.033	.0025
Total leaching expense		$382 50	$0.849	$0 0640

have been found necessary at Kennecott, but changing the rates somewhat to conform with more usual conditions.

It should be especially noted that the above is the leaching expense only. No charges are included for overhead, mining and crushing the ore, tailings disposal, freight to smelter and smelting charges, or selling expense. Little if any profit could be shown in leaching such a lean ore, if all these charges had to be borne by the leaching plant. But in the case of treating tailings from a primary concentrator, as at Kennecott, it is perfectly proper to charge the mining, crushing and tailings disposal to the main plant, which would have to bear this expense if the tailings were not treated, and under these circumstances it is possible to show a profit with very lean ores. In this connection it should be noted that ammonia and steam expense, which are the two largest items, vary not only in proportion to the tons of ore but also in proportion to the copper extracted. Hence it is not so expensive to treat lean ores. Power, maintenance and supplies will vary as the tonnage, while labor is constant and not affected by either tonnage or production.

As for first cost, construction expenses vary a great deal with local conditions. In the light of past experience, and under normal conditions, it is thought that $300 per ton of ore-treating capacity per day would be a reasonable estimate of the first cost of a small plant as herein described. One large item that must not be overlooked is the initial supply of ammonia. Some 275,000 lb. of 26 deg. aqua ammonia or equivalent must be accumulated, and this may easily cost more than $30,000. Unless skill and foresight are used in manipulating the plant operations, "peak" demands for ammonia will at times call for a much greater supply. The foreman must aim to keep all his ammonia at work all the time, for idle solution represents not only an idle investment in itself, but calls for additional storage tanks, and is a positive loss from leaks and evaporation.

Canaan, Conn.

Semi-Annual Meeting of American Institute of Chemical Engineers

Dr. John C. Olsen, secretary, has announced that the summer meeting of the American Institute of Chemical Engineers will be held at Boston, June 18 to 21, inclusive. A symposium on Electric Furnaces is being prepared. Further details regarding the program will be given in an early issue.

New Jersey Chemical Society

Colonel F. M. Dorsey of Cleveland, Ohio, Chief of the Development Division of the Chemical Warfare Service, will give an illustrated lecture before the New Jersey Chemical Society on Monday evening, April 7. The lecture is entitled "Activities of the Development Division of the Chemical Warfare Service," and will deal particularly with the development of manufacturing methods for mustard gas and for dorsite, or activated charcoal, with which Colonel Dorsey has had considerable to do.

Another item of present interest is a general discussion on "Permanent Results From Wartime Necessities" led by Professor R. G. Wright, of Rutgers College.

Dinner will be served at Stetter's Restaurant, Newark, at 6:30.

Imports and Exports

The Bureau of Foreign and Domestic Commerce of the Department of Commerce gives out the following statistics of imports and exports for January, 1919:

IMPORTS AND EXPORTS OF COPPER, BY CLASSES

Imports

	Gross Tons	Copper Content, Lb.	Value
Ore	11,697	2,919,767	$643,777
Concentrates	9,379	2,505,000	647,600
Matte and regulus	4,341	4,501,623	894,623
Unrefined, etc., in bars		5,065,683	1,256,250
Refined, in bars, plates, etc		4,019,469	983,753
Old, etc., for remanufacture		1,676,525	258,446
Composition metal		3,141	565
Copper manufactures			

Exports

	Gross Tons	Copper Content, Lb.	Value
Ore	1,530	318,946	$65,303
Concentrates			
Unrefined, etc., in bars			
Refined, in bars		72,757,340	18,381,796
Composition metal		8,882	3,238
Old and scrap		25,040	4,518
Pipes and tubes		356,340	137,861
Plates and sheets		3,130,974	884,669
Wire, except insulated		3,289,411	963,793
All other manufactures			526,138

IMPORTS AND EXPORTS OF GLYCERINE, BY COUNTRIES

	Lb.	Value
Imports (total)	15,807	$4,741

Exports

Country	Lb.	Value
Azores and Madeira Is.	163	$30
Norway	4,000	4,000
England	100	35
Bermuda	25	18
British Honduras	14	9
Canada	72,474	40,157

Future of Industrial Organic Chemistry

Brief Review of the Several Groups of Industries Depending on Organic Chemical Development, Such as Food, Clothing, Fuel, Drugs and Arts—The One-Plane Basis of Studying Organic Reactions Should Be Abandoned for the Spatial Energy Theory Advanced by Michael

By HAROLD HIBBERT

WITH regard to the late war it may be accepted as a truism that the peace and safety of the whole world rested on a far-reaching knowledge of the underlying principles of scientific and technical chemistry.

A review of our chemical knowledge, both scientific and applied, shows that prior to 1914 the chemistry of the aromatic compounds had been moderately well developed in this country, while that of the aliphatic had been more or less neglected. The reason for this is probably traceable to the influence of the German school of thought. Inasmuch as there existed in Germany large supplies of the raw materials necessary for the production of aromatic derivatives such as toluene, benzene and naphthalene, from which dyestuffs and pharmaceutical products are manufactured, it was natural, in view of the world markets obtainable for these finished materials, that this field should have been developed much more intensively than that of the aliphatic compounds such as the products from wood distillation, grain alcohol, fats, oils, gasoline, etc., all of which were imported products. Not only this, but the dyestuff industry forms, more than any other, the pivot around which so many different manufactures revolve.

In addition, it has always been tacitly assumed that the aliphatic compounds, especially those of saturated character such as the hydrocarbons (gasoline, etc.), are relatively inert materials, and consequently much less "plastic" than the aromatic derivatives; in other words, less capable of being transformed commercially into other products of industrial importance.

Four Main Divisions of War Requirements for Chemists

If we review the war requirements, we find that they may be divided, in so far as the chemist is concerned, into four main divisions:

1. Foods and food products
2. Medical and pharmaceutical supplies
3. Explosives and their intermediate derivatives
4. Poison gases.

A consideration of these shows that the aliphatic chemical compounds have played a rôle equal, if not superior, to the aromatic derivatives. In consequence, university professors, graduate students and technical chemists have, in many cases for the first time, been able to acquire a deep and far-reaching knowledge of the properties of aliphatic substances. If during the last forty years we have specialized on the technical application of the aromatic bodies, it is because it "paid to imitate Germany," but the prediction may now be made with safety that the industrial progress of the next half century will be intimately associated with the development of the chemistry of the aliphatic products.

A consideration of the subject will show that our necessities, comforts and luxuries are all closely related to products of the former class. This is clearly proved among other things from a consideration of the immense capital tied up in the manufacture of products of an aliphatic character. Thus with regard to foodstuffs, we have the vast industry of the edible oils, palm, cocoanut, cottonseed, soya bean, peanut, fish oil, etc.; and closely allied to this, the cyanamide fertilizer industry.

For our heat and light, we require gasoline and candles. Our clothing is derived from cellulose, either in the form of cotton or as artificial silk. Of our medical supplies, it is only necessary to mention such materials as glycerine, methyl and ethyl alcohols, formaldehyde, paraldehyde, chloral, etc. In the matter of luxuries, the moving-picture industry depends on a supply of cellulose derivatives either in the form of nitrate or acetate, while in the late war the most deadly of the various toxic gases employed was the so-called "mustard gas," which in addition to the products already mentioned is also a representative of the aliphatic series.

Value of Aliphatic Materials

Some idea of the value of these materials may be obtained from the following figures:

Value of cotton crop (1918)[1]	$1,616,207,000
Value of natural gas (1917)[2]	142,089,334
Value of products of wood distillation (1914)[3]	10,236,332
Domestic production of vegetable oils (1917) lb.	2,159,335,000
Domestic production of animal and fish oils (1917)[4] lb.	1,636,451,000
Domestic production of butter (1917) lb.	1,369,500,000
Total, lb.	5,165,286,000

The imports of fats and oils in 1917 amounted to 636,288,306 lb., while 584,254,000 lb. were exported. If we compare these with a total value of $40,044,427[2] for the entire output of crude coal tar products (tar, light oils and naphthalene) for 1917 the difference is striking.

The edible oil and fat industry is one of the first magnitude, and yet it will be admitted that the scientific principles regarding the hydrogenation of vegetable oils were first developed scientifically in France, then technically in Russia, Germany and England, and last of all in this country. As in the case of many of the most important technical developments, the work may be traced in its original conception to the scientific researches of Frenchmen, in this case Messrs. Sabatier and Senderens.

[1]Figures supplied through kindness of Department of Commerce.
[2]Figures supplied through kindness of Department of the Interior.
[3]Figures supplied through kindness of Department of Agriculture.
[4]Figures taken from Bulletin No. 769, Department of Agriculture.

While it may be allowed that this country has carefully followed the European patent situation, and endeavored to take advantage of it and improve on the same, yet in so far as the main general scientific aspects are concerned, it has shown relatively little scientific originality. Thus while celluloid is distinctly an American invention, the underlying scientific facts connected with the manufacture of stable nitrocellulose were largely developed through European studies. Without a knowledge of these fundamental properties it would not have been possible to proceed to the discovery that celluloid can be manufactured by compounding cellulose nitrate with camphor. The same holds true with regard to cellulose acetate and xanthogenate, the latter employed in the manufacture of artificial silk.

Universities Responsible for Neglect

There can scarcely be any doubt that the universities are in large measure responsible for the neglect of the study and technical application of the aliphatic derivatives. This neglect would seem to be to a large extent traceable to the faulty method of instruction, and the inability to make a student visualize the products with which he is called upon to deal. In other words, organic chemistry has been made a subject of "blackboard one-plane valency impressions" rather than a consideration of the energy and spatial relations of the constituent atoms in the molecule, and in this latter connection, it is difficult to understand why the work and theories of Michael have not been given much more prominence. The importance of training the student to visualize the spatial relations of the atoms in all organic compounds cannot be overemphasized. Instead of the customary procedure of showing the model of the carbon atom in the one or two isolated cases connected with stereoisomeric and optical derivatives, or in the case of the benzene ring, it would seem desirable to have available, at every lecture on organic chemistry, models which could be constructed so that the nature of the spatial arrangements would be at once apparent to the students, and instead of the customary one-plane representation, it would be possible for them to visualize at a glance the effect of the proximity of the atoms in the molecule and of the effect of the different forms of energy associated with the same, considered from the point of view of their spatial relations.

Thus all of the important properties such as substitution, ring formation, oxidation, reduction, etc., could be taught from this standpoint, and the value of an atom in the 1, 2, 3, 4, 5, etc., position relative to another atom attached to carbon, clearly defined and so thoroughly fixed in the mind of the student that, when called upon to advise on some process in connection with the manufacture of a synthetic product, he would never be at a loss to predict, at least in general terms, the nature of the material to be synthesized, and to indicate some procedure looking toward its successful manufacture.

While not wishing to detract from the interesting researches of Fry and Jones, or from the interesting discussions of Falk and Nelson, as well as of G. N. Lewis, it would seem, in so far as the technical side of organic chemical problems is concerned, that for the present the theories of Michael, though in some respects vague and indefinite, largely on account of the impossibility of providing all the quantitative data, yet at the same time do provide a working hypothesis which undoubtedly assists the research chemist to a remarkable extent in predicting the nature and course of chemical reactions and of the properties of unknown chemical individuals.

If a student learned to grasp thoroughly the fundamental principles underlying the relative energy values of the atoms in the molecule, and to obtain a more profound and comprehensive knowledge of the facts of catalytic phenomena bearing on organic chemistry, he would be placed to-day in a far more advantageous position for solving the various technical problems arising in connection with the development of outlets for the commercial and industrial utilization of naturally occurring products found in this country.

Pitfalls of the Young Chemist

The young research chemist in the industry is too apt to attempt to transfer his college knowledge of the "type properties" of any chemical compound to the derivative to be synthesized instead of realizing that the problem to be solved is in general one in which, for some reason or another, the "type property" has either ceased to exist, or has been considerably modified through the influence of certain groupings or atoms in the molecule. Thus he fails to realize that a reaction of any group such as carboxyl or hydroxyl, instead of representing a definite fixed property *per se*, is in fact rather a summation of properties representing a combination of the play of the various energies and affinities of the entire reacting atoms comprising the molecule; in other words, the group does not exist alone. It is this understanding and appreciation of the varied influence of each atom in the molecule on each other atom which enables the trained chemist to predict chemical phenomena and properties, and as the ability to predict is a true measure of the ability to invent, and invention and progress naturally move hand in hand, the importance of such knowledge is readily apparent.

Much has been heard of the various psychological tests employed in the Army, and it would seem that equally satisfactory tests applicable to college men desiring research positions should be devisable. One suggestion in this connection is that at the conclusion of the usual course of organic chemistry a series of seminar exercises should be given in which, by the use of models, the students should be called upon to give indications of their ability to predict the nature and properties of different chemical compounds. Thus, for example, with a compound of the formula

$$\begin{matrix}CH_3\\CH_3\end{matrix}\!>\!CCl - CH = CCl - CH_2 - CH_2 - NH_2$$

which preferably should be written

$$\begin{matrix}CH_3 & CH_3\\ & CCl\\ HC & NH_2\\ \| & |\\ CCl & CH_2\\ & CH_2\end{matrix}$$

the student could be asked to set up the carbon models, and then, with these in full view, he asked to predict the effect of various reagents on the various atoms in the molecule; in this case, the tendency toward ring formation, the action of alkalis, effect of oxidizing

agents, removal of halogens, properties of the different hydrogen atoms, etc. A satisfactory answer to such questions would, from the technical research standpoint, provide evidence much more valuable of the man's probable research ability than reams of paper dealing with his knowledge of the dozen different ways for making, let us say, ethane or other derivatives.

The fact that acetaldol can be made by the condensation of acetaldehyde with alkalis, etc., and the various conditions which must be observed in carrying out such a reaction are of less importance than the ability to predict, for example, just in what manner, say, acetaldehyde would condense when mixed with some other aldehyde, for instance, isobutyric aldehyde.

The same is also true of the ability to foresee, for example, the point at which substitution will occur when a hydrocarbon, for instance, propane, hexane, etc., is subjected to the action of bromine, etc., or again where it will occur in the case of acids and acid chlorides.

These problems and many others of vital interest and importance are to be found discussed at length in the published work of Arthur Michael.[5]

The Training of the Professor

So much for the training of the chemist. With regard to the training of the professor, it would seem that he also stands in need of overhauling. In the first place he has been, from time immemorial, both badly underpaid and overworked, and both of these conditions call for urgent and vigorous action. No professor or instructor can undertake research work unless he is

1. Competent to undertake the same
2. Has adequate facilities in the way of post-graduate men and equipment
3. Has the necessary time to devote to it
4. Is adequately recompensed so that he can be free to devote himself to the scientific side of the subject without the necessity of burdening himself with onerous and uncongenial outside employment.

Granting this, there still remains the fact that the average university and college professor has hitherto not been in touch with the problems of the industrial world. He has, in fact, in many cases rather scorned any association with such, and naturally the industry has resented this and returned the feeling with interest. If the war has shown one thing, it is this, that the future generation of research chemists and chemical engineers will expect from their professors something more than a general knowledge of the theory of the subject, and will at least expect that they shall be conversant with the better known technical applications. As for the detailed knowledge, presumably this will be left to the director of the department of industrial chemistry, between whom and the professor of pure chemistry there should naturally exist the closest kind of personal friendship and scientific co-operation.

Universities to Teach Industrial Chemistry

Various universities, including Harvard, have now made a start in this direction by establishing departments of industrial chemistry, and it is to be expected that other universities such as Yale, Princeton, etc., will follow her lead. Unless this is done we shall undoubtedly fall behind other countries, as witness the marked progress being made along these lines in England and the subsidizing of English university professors by manufacturers of explosives and other chemicals with a view to utilizing the services of their highly trained intellects in the solution of different technical problems.

Various corporations in this country have already allocated considerable sums of money for similar purposes and it is now for the universities to decide as to how far they can, and will, co-operate with them in this. Instead of a series of Mellon Institutes dotted over the country, the more logical development would seem to lie in the creation of strong departments of industrial chemistry at the leading universities.

That there need be no lack of subjects requiring investigation is especially evident when we consider the natural resources of this country, and how closely their development is identified with a thorough knowledge of the chemistry, in particular, of the aliphatic compounds.

In this connection it may be of interest to take up the subjects indicated previously, namely:

1. Food products
2. Clothing
3. Fuel for light and heat
4. Medical supplies
5. Luxuries and arts,

and to glance briefly at the progress and developments which have been made regarding these during the last few years, and at the same time to indicate the general trend of future industrial development.

Slogan Should Be "Tolerate No Waste"

In the first place, in view of the recent prodigal waste of the world's resources, it is now necessary to "think internationally" as well as nationally. After all, the world's resources are not unlimited, so the slogan of the chemist from now on should be, "We shall tolerate no waste." As an illustration of this, if it can be shown that our entire supply of ammonia can be obtained from the coke oven gases, then it would seem logical to enact the necessary legislation to enforce the introduction of the recovery system to the entire coke industry, while other processes, such as the manufacture of cyanamide, which encroach on our limited available supply of coal and power should, if necessary, be excluded from the manufacture of such material.

In the same way if we can produce the country's requirements of alcohol and acetic acid economically from such materials as waste wood, which it must be admitted seems rather unlikely, then from the "world conservation standpoint" these processes should logically receive more attention than when prepared by other methods involving the use of raw materials, limited in extent and capable of being adapted more effectively and efficiently to other branches of the arts. In this connection it is also true that the manufacture of ethyl alcohol from waste pulp sulphite liquors, if possible from a commercial standpoint, is also true conservation when considered from the point of view of the utilization of foodstuffs such as corn, etc., for the same purpose.

What can the technical chemist do to assist in bringing down the high cost of living? How can the universities, colleges and scientists assist him? A brief attempt will be made to answer these questions. Concerning the list previously quoted, namely, food products, clothing, light and heat, medical supplies and luxuries, an examination will show that they are ar-

[5] See, among others: *Journ.* pr. chem. 60, p. 286-409 (1899); 68, p. 487-520 (1903). Berichte 34, 626; 4028 (1901); 39, 2138 (1906). *Journal* Amer. Chem. Soc. 32, 991 (1910); 40, 1674 (1918); 41, 393 (1919).

ranged in approximately the order of their importance with regard to the development and protection of the individual.

Food Products

For the first time in their lives millions of people have been forced to learn, during the last four years, something regarding the nature of food and food products. As is well known, the bodily requirements comprise three main divisions, namely, fats, carbohydrates and protein, a shortage of any one of which proves disastrous.

With regard to fats, these are aliphatic compounds, esters of glycerine and fatty acids, and owing to their utilization along lines other than for food, a very pronounced world shortage soon occurred in this field after the outbreak of the war. As is well known, fats are utilized for the manufacture of glycerine and fatty acids, the latter being converted into soap and various other useful chemical products, while the glycerine finds its main outlet in the manufacture of explosives, cordite, dynamite, etc.

An increase in the available supply of edible oils thus became imperative, and the production of cocoanut, peanut, palm, soya bean and other vegetable oils, together with animal fats, was stimulated to a very marked extent, and yet in spite of this the shortage abroad remained very acute. All of these oils represent aliphatic derivatives, regarding which much research work is necessary and from which, in turn, marked technical advances may be expected. Thus soya bean oil is comparatively a new product and is produced now in such large quantities that additional outlets for the material are desired. In 1918 we imported from China and Japan 335,983,492 lb., having a value of $35,454,639.

The properties, chemical, physical, etc., of peanut oil would seem to repay investigation, and the general question of prevention of rancidity in oils, especially in the case of cocoanut and palm oils, is a subject calling for the attention of the chemist. A good cheap commercial method has been developed for the deodorizing of fish oil so that the low grades, which on account of their high fatty acid content cannot be used for purposes of hydrogenation, can now be employed for the manufacture of glycerine and soap.[6] This question of the hydrogenation of fatty acids is a field offering considerable scope for the research chemist, as is also the problem of the catalytic reduction of unsaturated aldehydes and ketones whereby unsaturated alcohols may be obtained.

The oils extracted from peach kernels and other waste raw materials have also been shown to provide useful substitutes for olive oil as salad dressings, etc., so that a more extensive use for these materials may be predicted.

Carbohydrates

There also developed during the war period a considerable shortage in the supply of sugar, due in part to the inability to transfer supplies from one part of the world to another, notably from Java and other points. In consequence of this, the saccharine industry was developed both here and abroad, and some idea of the value of it may be gained from the fact that at one time in England this material sold for about $80 per pound, and it became customary for individuals to carry around small saccharine pills for the purpose of sweetening their beverages. In view of the fact, however, that saccharine is not a foodstuff, it is not likely that the manufacture of this material will be pushed to a considerable extent after the war except in the case of a few industries such as the mineral water trade, and up to the present no other substitutes have been developed and in fact they do not seem desirable. There would seem, on the other hand, to be a good opening for the development of special carbohydrate material capable of being assimilated by people suffering from diabetes.

Protein

It is probable that in the domain of the protein foodstuffs most progress is possible. The extensive researches carried out, for instance, at Yale might well be utilized for the purpose of testing out the relative value of a pronounced protein diet in comparison with one entirely vegetarian. It would be of considerable interest to divide, say, a given class into two such squads, and then to have a full report at the end of a nine-months' period as to the mental and physical condition and development of the individuals in each series.

It does seem surprising that in view of the well-known facts regarding the protein content of peas, beans, lentils, cheese, etc., there should still exist doubt in the minds of college men, chemists and others that such materials are not adequate to provide the full protein requirements. When men of such eminence in the inventive world as Dr. Leo Baekeland and others testify that their best work was done on a strictly vegetarian diet, it provides considerable solid ground for the assumption that such conduct would also be of advantage in other cases.

In this connection a few facts concerning the soya bean industry may be of interest.[7] The bean itself is grown principally in China and Japan, and the development of the oil industry has been most marked within the last twelve years. In fact, had it not been for this commodity the probabilities are that many of the soap factories would have had to suspend operations during the last two or three years. It is claimed that this country could use some 600,000 tons of soya bean oil annually, corresponding to 6,000,000 tons of soya beans. In 1918 the total imports from Manchuria were approximately 1,000,000 tons of beans, equivalent to 100,000 tons of oil. There were imported into this country in 1917 approximately 132,000 tons of oil, while the domestic production amounted to 21,000 tons.

Soya bean oil resembles linseed oil to some extent, that is, it is a drying oil and has been used largely in the manufacture of paints, linoleums and similar products. On the other hand, it is a valuable constituent of salad oils and butter substitutes and in China forms the staple food oil of large classes of the people.

Dietetic Value of the Soya Bean

Due to the fact that with ordinary methods of cooking soya beans remain rather unpalatable, their use, as such, has not been practiced to a great extent, but the

[6] It is stated that in consequence of the inability of trawlers to operate in the North Sea and other portions adjacent to the British Isles, the fish have multiplied very rapidly, so that it is expected the fishing industry will be very active during the next few years.

[7] The data are compiled from an interesting article, "The Romance of the Soya Bean," by L. S. Palen, published in the January (1919) number of *Asia*, the journal of the American Asiatic Association. The U. S. Department of Agriculture Bulletin No. 439, "The Soya Bean," by Piper and Morse; and No. 769, "The Production and Conservation of Fats and Oils in the United States," by Bailey, also contain much interesting and valuable information.

various sauces, curds, cheeses, etc., made from it have been shown to possess such marked dietetic value that there is likely to be a rapid increase in the future consumption of these products which would tend to lower the high cost of living. Analysis shows the presence of:

	Per Cent
Proteins	30 to 46
Oil	12 to 24
Carbohydrates	24 to 28

According to Osborne and Randall,[8] "The proteins of the soya bean, unlike those of other leguminous seeds thus far investigated, are adequate for promoting normal growth. . . . So far as we are aware the soya bean is the only seed hitherto investigated, with the possible exception of flax and millet, which contains both the water-soluble and the fat-soluble unidentified dietary essentials or vitamines."

However, it is not possible to enter into a lengthy discussion of the subject except to point out that the valuable results obtained in dietetic studies at Yale and other universities should be made more readily available and that at least one or two lectures on this subject should be devoted to the same in any college course on organic chemistry.

Cheap Fertilizer a Necessity

With regard to the whole question of food supply, it is necessary that cheap fertilizer should be provided, and the vigorous and active research being carried out with regard to the recovery of potash from blast furnaces and the cement industry, together with the various new methods for the fixation of atmospheric nitrogen, would seem to warrant the hope that considerable success may be expected from the experimental and technical researches at present in progress.

At present the Haber process would seem to be the cheapest method of nitrogen fixation, but it is rational to assume that the maximum efficiency with regard to the arc process has not been reached, and that valuable improvements and developments may be expected along these lines. Furthermore the difficulties incidental to operating the Haber process at lower pressures are, as yet, far from being solved.

With regard to various by-products of the food industry, some outlet, for example, should be found for cottonseed hulls and similar materials. Preliminary experiments carried out by the writer appear to indicate that when compounded with nitrocellulose cork substitutes may be made, possibly applicable to manufacture of cork stoppers, lifebelts, etc., and this is only one of many uses to which this material might be applied.

Of other points of interest connected with the food industry, there is the question of obtaining suitable oils for use in the manufacture of tin plate and the "quenching of steel." Instead of the edible palm oil other cheaper material such as cottonseed, pine oil, etc., are apparently capable of substitution.[9] Finally, with regard to the extraction of oil from the oil cake, it is recognized that the best solvent for this purpose is trichloroethylene. This is obtained from acetylene and chlorine and is not manufactured in this country at the present time, although its synthesis is not a difficult matter to carry out commercially and it is to be hoped that domestic manufacture of the material will be undertaken.

With regard to the second item listed above, namely, clothing, we find on investigation that in addition to the use of cotton as such, the manufacture of artificial silk has been developed to a remarkable extent in this country in recent times. Furthermore, it was very evident during the last two years that the country's entire available supply of knowledge regarding the scientific character and fundamental properties of certain cellulose derivatives such as the xanthogenate, and particularly the acetate, was decidedly limited in extent. It is a startling fact that while the value of cotton and cotton products such as nitrocellulose, artificial silk, etc., produced in this country is far greater than that of the rest of the world combined, yet so far as a hasty search of the literature shows there has not been a single outstanding scientific paper published in this country on the constitution of cellulose.

We have allowed the European countries to develop the scientific data on these subjects, and then made a feeble, belated attempt to obtain control of the technical applications either by purchase or otherwise. It is regrettable that in the case of the one or two large companies which have carried out scientific work in this field they should have felt under no compulsion to communicate the broad scientific results to the general body of chemists, but prefer instead to surround the matter with a complete veil of secrecy. It is not in this way that the progress of any industry can be assured, and fortunately as a result of the war, this would now seem to be much better recognized.

Fuel for Heat and Light

When we consider the bearing of aliphatic chemistry on the question of heat and light, we find this country is by far the largest producer of petroleum and gasoline products, and not only this, but it is also the largest producer of benzol, of which advantage is now being taken in connection with gasoline mixtures for use in motor cars. There would also seem to be a valuable field in the development of materials of low nitration for admixture with kerosene for use as a motor fuel. Furthermore, it is a pity that there should still be any waste of natural gas, and this material would seem to warrant the close attention of chemists and technologists from both the scientific and industrial standpoint. The action of halogens, condensing agents, contact reactions with unsaturated derivatives, etc., are all interesting fields.

The cracking of petroleum has been developed to a remarkable extent, but it would seem that there is still room for processes involving the use of other contact materials which would enable this operation to be carried out at both a lower temperature and pressure. Possibly additional research would show the advantage of metallic chlorides other than aluminium. The reactions of hydrocarbons with sulphur chlorides would also repay investigation, and the interesting experiments recently carried out with nitrosyl chloride[10] possess much interest both for the scientist and for the technical chemist.

Prior to the war, this country was almost entirely dependent on Germany for its pharmaceutical supplies. In tracing the reason for this, one fact is quite evident, namely, the close co-operation which existed there

[8] *Journal of Biological Chemistry*, December, 1917.

[9] See Department of Agriculture Bulletin No. 769, page 23, "The Production and Conservation of Fats and Oils in the United States" (1919). This is a very valuable monograph, containing, as it does, the latest available information on the subject of edible oils.

[10] *Journal* Amer. Chem. Soc., Vol. 41, p. 368 (1919).

between the universities and various pharmacological institutes on the one hand, and the industry on the other. Such well-known remedies as antipyrine, veronal, etc., were developed in university and not in technical laboratories. We still find it necessary to consult German text books and monographs for much of our information, and it now appears that the compilation and publication of such treatises on highly specialized subjects were carried out in many cases at public expense.

Is it asking too much that this Government should co-operate both actively and financially in the founding and support of a national pharmacological institute such as proposed by Dr. Charles Herty, and at the same time show its willingness to undertake the financing of the publication of scientific memoirs not warranted commercially through the usual channels?

Inviting Field for Organic Research Chemist

The scientific development of the relation of constitution to pharmacological action is one of the most inviting fields for the organic research chemist at this moment, and it is highly desirable that there should be a much closer co-operation between the biologist on the one hand, and the organic chemist on the other. It would be a grave mistake, for instance, not to take advantage of the wonderful spirit of co-operation in this field, developed as a result of their combined activities in the domain to toxic war gases. It is, for instance, inconceivable that the salicylates should represent the only type of compound best adapted to the use to which they are put, and it would seem extremely probable that active research would develop the use of better and more suitable products.

If for instance just one-half of the scientific work expended on the preparation and investigation of toxic war gases during the last two years were devoted to investigations looking to a remedy for tuberculosis, it is reasonably safe to assume that some cure would be found. In this connection it is necessary to recall the wonderful advances that have been made in the domain of biological chemistry, and referred to by Francis H. Carr in a recent lecture on "The Synthetic Organic Chemical Industry."[11]

Cure for Consumption Possible

For example, thyroxin, the principle contained in the thyroid gland, which regulates the rate of body metabolism, is now stated to be an oxyindole derivative of iodocyclohexane, and is so active that 0.3 mg. raises the body metabolism 1 per cent. The fact that thyroxin contains iodine is of considerable interest, since, as shown by the writer[12] and others,[13] a small trace of this element is sufficient to bring about the condensation of hydroxy, amino and imino derivatives. From the recent publication of Van Os[14] it would appear that the iodine present in thyroid preparations does not exert a marked influence, but in view of its remarkable activity as a condensing agent these results should not be regarded as final and conclusive. This is all the more necessary in view of the fact that in the case of tubercular patients the iodine content of the thyroid gland apparently varies appreciably from the normal, so that if some such connection could be traced, it might possibly provide a welcome guiding light as to a possible synthesis of a derivative capable of application to the cure of this terrible scourge.

When we consider broadly the nature of the products on which we depend for our enjoyment, we are again brought face to face with the aliphatic derivatives. The amusement of a large portion of the population at the present time is derived from moving-picture houses, and as is well known the films are made from cellulose nitrate or acetate. Our paper drinking cups and food containers are coated either with paraffine or nitro-cellulose and the casing of the sausage we eat is also probably a modified cellulose derivative.

No matter to what domain of the fundamental requirements of human activity, physical or social, we turn, it is evident that we are brought face to face with the properties and industrial applications of the aliphatic chemical compounds. Not only is it the duty of the chemist to develop the scientific and commercial application of such, but also to foresee and protect the individual from the harmful effects of abnormal natural and artificial conditions. Thus at the present time we are faced with national prohibition, and as this will render idle an immense amount of equipment, it is to this extent destructive of industry.

Problem of the Chemist

The problem of the chemist is, therefore, to provide other outlets for this valuable machinery, and since the production of spirituous liquors is essentially a fermentation process, the attention of the chemist should naturally be devoted to new developments along such lines. Thus the manufacture of lactic, butyric and citric acids could be still further developed together with special sugars such as maltose and food products derived from these, for example, lacto-maltose, etc. The manufacture of special sugars could also be undertaken and it is natural to assume that there will be a much increased demand for essential oils and flavoring extracts for the soft drink industry.

In the second place, one of the effects of prohibition will be to diminish the supply of fusel oil, in turn of amyl acetate, so that in all probability brewery equipment could be utilized for the manufacture of substitutes for these materials; in fact, certain cheap derivatives of lactic acid would form useful substitutes for amyl acetate.

Other Fields for the Chemist

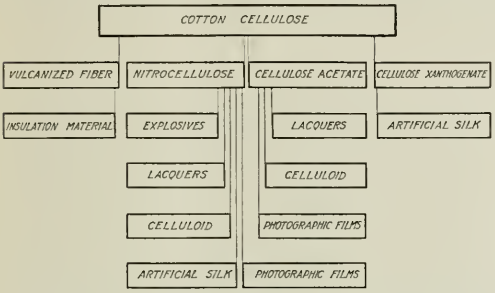
It is not possible to more than mention other fields in which the services of the chemical expert in aliphatic chemistry can find a suitable outlet such as utilization of acetylene, sulphite pulp waste liquor, and especially in the utilization of waste wood products, etc., but the diagrams shown herewith are of interest as indicating the varied outlets for one raw material, namely, cellulose. These show outlets already developed, but indicate little or nothing of the vast unexplored territory still remaining.

Thus, with regard to nitrocellulose and cellulose esters generally, there is a very fertile field for a series of investigations relating to the question of solubility of these products in organic solvents through which much light might possibly be thrown on such problems as the physico-chemical nature of solution, the colloidal state, the theory of partial valency, etc. All of these await in turn the development of some theory as to the structure of the cellulose molecule. The chemistry of the cellulose esters is as yet a com-

[11] *Journal*, Soc. Chem. Industry, Vol. 37, p. 425 (1918).
[12] *Journal*, Amer. Chem. Soc., Vol. 37, p. 1748 (1915).
[13] D. R. P. 241,853; 250,326.
[14] *Pharm. Weekblad*, Vol. 55, pp. 1426-31 (1918); Amer. Chem. Soc. Abstracts, Vol. 13, p. 362.

paratively unknown field, regarding which the industry is forced to rely almost entirely upon empirical data.

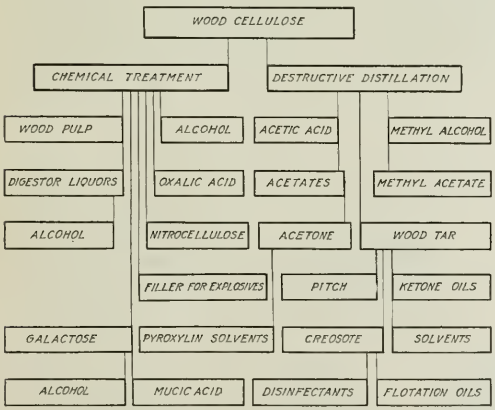
In another direction when we turn to the manufacture of celluloid in this country, the furtherance of the industry itself is dependent on the good will of the Japanese Government in selling us camphor. It would



seem imperative on the part of the American scientific chemist and chemical manufacturer to solve this problem by undertaking the manufacture of synthetic camphor or by carrying out a vigorous search for substitutes for this material, or by doing both. In this connection it would be of considerable assistance and value to the research chemist if the celluloid companies would be willing to explain for their benefit something with regard to the special and peculiar properties which a true substitute must possess.

The Wood Distillation Industry's Future

In the utilization of the constituents of the oils obtained from wood distillation, there is an interesting field of vast extent open to the research chemist. In view of the difficulty which will be experienced in obtaining raw material in Europe during the next twenty



or thirty years, it would seem that the wood distillation industry in this country is in an exceptionally favorable situation for development, and for the supply of products such as solvents for the varnish, artificial leather and lacquer industries; while as regards beechwood creosote, beechwood creosote carbonate, guiacol, etc., the country should be self-sustaining and not have to rely on foreign manufacture.

It is the function of the organic chemist to find outlets for the vast surplus production of aliphatic derivatives such as butyl alcohol, methyl alcohol, grain alcohol, acetone, etc., and to ascertain how far the new scientific facts developed during the last few years by the use of bodies such as phosgene, sulphur, chloride, aluminium chloride and of contact materials, for example, oxides of aluminium, thorium, nickel, etc., may be applied commercially.

In view of the extent to which the aliphatic compounds enumerated above enter into all of our daily life, the importance of a thorough study of these cannot be overemphasized. To assist in this the university and college teachers must of necessity themselves have learned to grasp the fundamental facts concerning the nature of these natural products so that their students may be trained to acquire the habit of thinking of such not merely in the light of formulæ made up of so many letters and strokes, but as combinations of different forms of energy capable of the most diverse transformations.

The old idea of fatty hydrocarbons as inert material must also be relegated to oblivion, and the mind directed to ascertaining how far such products, by the employment of better known catalytic and other methods, can be rendered valuable to the industry.

2 Rector Street,
New York City.

Good Flotation Oils From Crude Tar Products

The new "flotation" process for the concentration of various sulphide ores has had a rapid development in the last few years, and as a result the demand for flotation oils to use in the process has been very great. Pine oils and tar oils obtained by the distillation of Southern pine have become standard flotation oils, but the tar oils obtained by the destructive distillation of hardwoods have not been used so widely.

Recent investigations by the chemists of the Forest Products Laboratory, U. S. Forest Service and the Bureau of Mines have shown that several hardwood tar oils have a very high flotation value. Some of the crude tar products obtained in the ordinary operation for making wood alcohol made especially good flotation oils and in general these crude products were better than any of the redistilled oils obtained by further refining.

Zinc for Rail Bonding

The American Zinc Institute, in its campaign to increase the uses of zinc, is advocating spelter for rail bonding purposes. One of the largest street railway companies recently made a considerable purchase of spelter for use in the manufacture of its Nichols joints. Engineers in charge of bonding operations report that, viewed from price and adaptability standpoints, spelter is unexcelled for such work. Zinc is comparatively plentiful and relatively cheap, and in many directions it is satisfactorily taking the place of more expensive metals.

Decomposition of Metals

Owing to lack of space the second installment of the article on "Decomposition of Metals," by Col. A. J. Krynitzky, is omitted from this issue, but will appear at an early date.

Observations on So-Called "Flakes" in Steel

An Examination of Nickel Steel and Carbon Steel Transverse Test Bars Showed That Abnormalities in Fractures Were Associated With Impaired Physical Qualities and Exhibited More or Less Minute Slag Inclusions, While No Parallelism With Micrographic Characteristics Could Be Demonstrated

By HAAKON STYRI

MOST steel works which have produced war materials have had the annoying experience of getting rejections on account of low physical tests, particularly elongation and contraction, often associated with irregular spots in the fractures.

These irregularities are popularly known by the name "flakes," a name which may serve the purpose when meant to include all types of irregular spots in fractures, but is poor terminology when used for certain types without further qualification. Some accompanying pictures of fractures will show different types of such "flakes." We have small bright spots of a fine crystalline mass radiating from a kernel (Fig. 1), coarse crystalline shiny, leafy spots, the so-called "snowflakes" (Fig. 2), fibrous laminated spots (Fig. 3), smooth velvety bright spots (Fig. 4), flaws and holes (Figs. 5 and 7), and sometimes no distinct spots, but the whole fracture, indicating "rotted" material (Fig. 8).

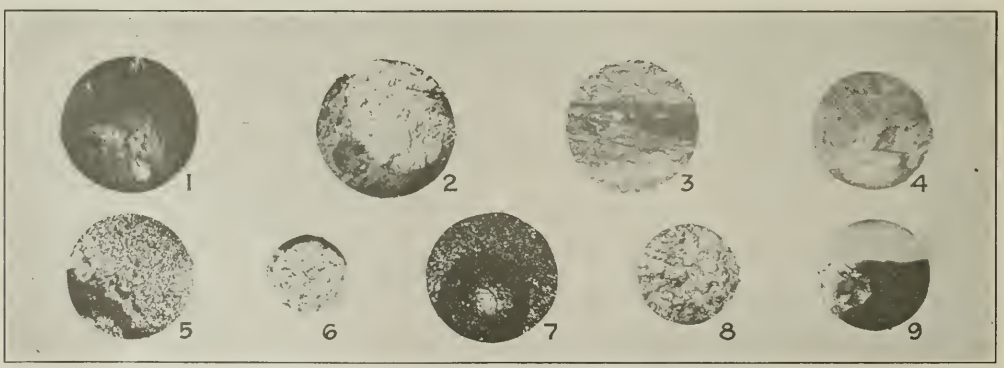
Flakes have mostly been noticed in transverse test bars from nickel steel, but are also found in other classes of steel, and there is a multitude of opinions as to their cause, ascribing them to the melting, the casting, the forging, the heat treatment, or to any combination of these operations. That no single theory covers the whole problem is evident, since flakes still are very frequent in spite of all the work that has been done to eliminate them. So far it seems fairly well established, however, that the ordinary chemical analysis of the heat does not indicate whether flakes will occur in test bars or not.

The present notes, which are very far from being complete, owing to the difficulties of securing research material during war time and the limited time at the author's disposal in which to prepare the samples, perform the microscopic examination and the photographic work, are presented in the hope that they will throw some additional light on the problem. With the effective and untiring help of Prof. F. Crabtree of the Carnegie Institute of Technology, the author succeeded in getting most of the research material from several interested steel companies, and a little from inspectors of ordnance for the Army and Navy. In the paper, the sources are named "party A," etc., because the companies do not want their names mentioned. The different nickel steels were made in electric, acid, and basic open-hearth furnaces; the carbon steels were made in an acid open-hearth.

Microstructure Inconclusive

Microstructure of the first samples of test bars from party A sent to the author for examination are shown in Figs. 10, 11 and 12, which show respectively the fractures of a nickel steel test bar with a good normal cup fracture, and of rejected bars with an irregular and a fibrous laminated fracture. Information on the exact heat treatment could not be obtained, but was thought to be practically the same, while the chemical composition of the steel is identical. Figs. 13 and 14 give the microstructure of a similar nickel-steel with another heat treatment and representing respectively the structure of a test bar with good cup fracture and of a rejected bar with an irregular fracture.

The metallographic analysis showed that different kinds of microstructure (and therefore heat treatment) have no influence on the actual occurrence of flakes.



FIGS. 1 TO 9. VARIOUS TYPES OF ABNORMAL FRACTURES

Fig. 1. Fracture of bar 218 from party B, with bright radiating flake. × 2. Fig. 2. Fracture of bars from party D; coarse-crystalline shiny "snowflakes." × 2. Fig. 3. Fracture of carbon steel bar 2399-2 from party G, with fibrous laminations. × 2. Fig. 4. Fracture of carbon steel bar 234 II from party F, with velvety flake. × 2. Figs. 5 and 6. Fractures of two adjoining test bars from piece 3872 furnished by party F; Fig. 5 shows flaws; Fig. 6 is normal cup fracture; see Table VI for physical properties. × 1.5. Fig. 7. Spherical flaw, crystalline in center, bar 3070 D, from party F. × 2. Fig. 8. Fracture of "rotted" metal in 55G1 from party F. × 2. Fig. 9. Shining, smooth flaw probably from an unwelded blowhole in M53D from party F. Smooth part is polished back for microscopic examination. × 2.

Flaky test bars and good test bars with cup fracture are both found with practically the same microstructure, which can be: pure sorbite, fine ferrite network with sorbite, coarse ferrite network with Widmanstättian structure, and with different kinds of sorbite, or ferrite with pearlite. But examples were found that show an improvement in the quality of the steel with proper heat-treatment, which, however, has not eliminated the flakes.

No Nickel Silicates in Nickel Steel

When an opportunity was given the author to examine the fresh fracture of rejected test bars with a binocular microscope it was found that the fractures showed a considerable amount of green slag particles. With this as a clue, I tried to ascertain the nature of such inclusions by microchemical analysis, which proved to be a very difficult matter because the slag particles were so very small. In the literature, it has been generally assumed that these faulty fractures mostly occur in nickel steel, and it was therefore thought probable that the slag particles might be some nickel silicate, and considerable effort was given to discover whether the slag particles contained nickel or not. Some slag particles were picked out of the fracture, under the microscope, by means of a fine needle, dissolved in HF or fused with Na_2CO_3, and a concentrated drop of the final solution tested with diphenylglyoxime, which gives a very sharp test for minute quantities of nickel, but no sign of nickel could be found.

In the expectation that at least some of the slag particles present in the steel would not go in solution, about 20 g. of a flaky bar was dissolved in 1:3 HCl on the hot bath and the residue filtered. It was found in several trials that the precipitate on the filter consisted of small distinct slag particles together with flocculent silica and MnO_2 and it was difficult to separate these masses. For separation a small flotation apparatus of glass tubing was blown and tried with some advantage, but the best method was to brush the dried filter with a fine brush whereby the larger slag particles could be taken off. Alundum crucibles for filtering also served the purpose well. Filtering on "ashless" filter, burning it and trying to determine the residue under the mineralogical microscope was not successful because the ashless filter contained too many crystalline substances. Good silk filters were much better, and with them it was found under the mineralogical microscope that the slag particles were of a glassy nature. Fig. 15 shows the slag particles found in 20 g. of steel. Testing for nickel with this larger mass gave no indication. But it was found that fusion with KNO_3 and Na_2CO_3 gave a strong reaction for Mn and it was also found that iron and SiO_2 were present. A test showing presence of calcium in concentrated solution might be mentioned, but it is possible that the glass flask was dissolved, and there has been no time to check this result.

These tests show at least some of the inclusions to be manganese silicates, which only confirms the work of others and the more important fact that no nickel-silicate is present. It is clear that on dissolving steel in acid, inclusions like MnS or very limy silicates will go into solution, and the pressure of such slag particles in the fracture can only be proved directly under the microscope or by the tedious and difficult method of picking them out and analyzing them microchemically.

Importance of Slag Inclusions

It was concluded that in the test bars from party A the slag inclusions played an important rôle in causing low physical tests, but it was, of course, of interest to find whether the same source for the trouble could be found in test bars from other concerns.

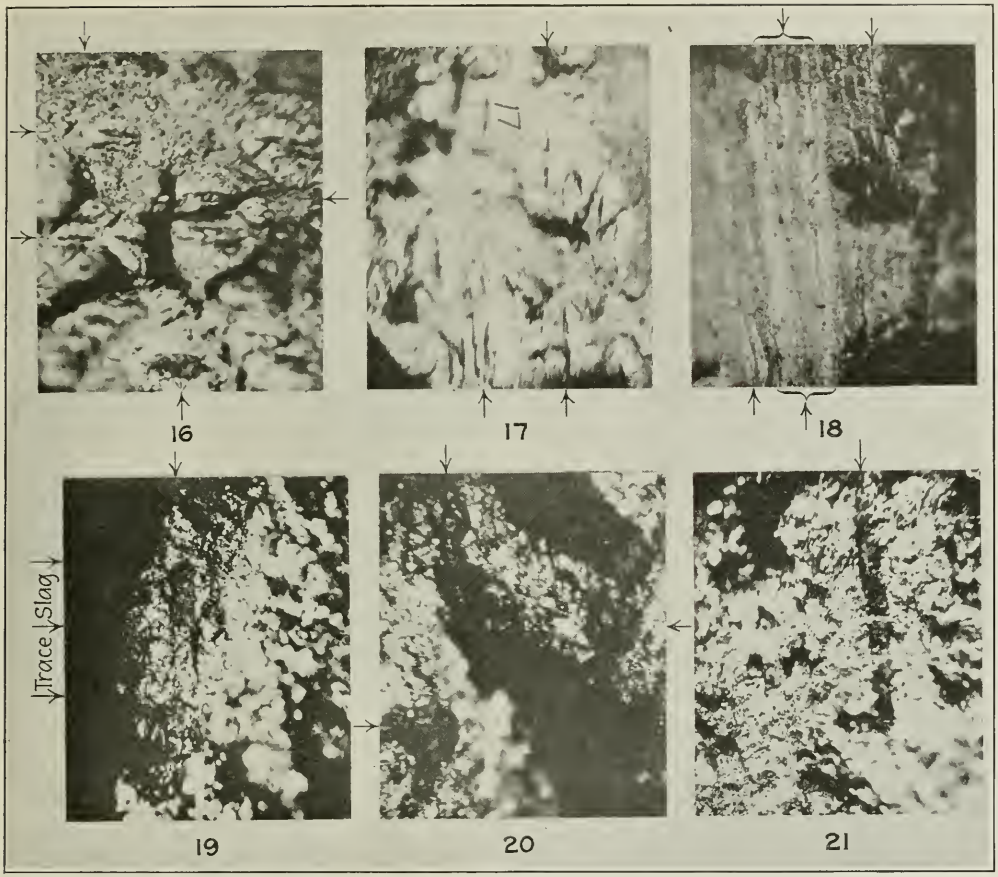
The opportunity was given to examine with the binocular microscope numerous freshly broken samples from party B. Examination was done in the following manner: Test specimens were taken serially as they were placed in the rack, their numbers noted, and the fractures examined with different magnifications. Corresponding remarks were jotted down describing as briefly as possible the general characteristics of the fracture, giving an idea of the number, color, and mode of occurrence of the slag particles. In some of the fractures some shining streaks called "traces" were also noticed, probably matrices from which slag had fallen; this could sometimes, but not always, be ascertained.

When this listing was finished the samples were then grouped according to the number of slag inclusions and the physical data were added (Table I). Study of this will show that there is a striking general connection between the number of slag inclusions and the elongation and contraction; but the elastic limit or tensile strength seems not to be affected.

Great pains was taken in the examination of the fractures of test bars with the binocular microscope, whereby a first approximate quantitative proof can be given of the influence of the slag inclusions on the physical qualities of steels with practically the same heat treatment, and particularly on the elongation and



FIGS. 16 TO 21. SLAG INCLUSIONS IN DEFECTIVE FRACTURES, BOTH NICKEL AND CARBON STEELS

contraction. It is most striking to find that in all good test bars examined either no slag particles or only very small round particles or traces of them are found.

It must, however, be taken into consideration that there is some variation in the mechanical tests because of variation in chemical composition and heat treatment, which latter is supposed to be practically constant, but is subject to the influence of shop conditions. The effect of different heat treatments, however, is practically excluded in six tests from the same forging (No. 843*), showing that the results differ both in breech end and muzzle end corresponding with the number of slag inclusions. The typical fracture of the poor bars of Table I is shown in Fig. 1, and photographs of the slag inclusions taken with the binocular microscope are shown at 20 magnifications in Figs. 16 and 17. A similar photograph of flaky fractures of bars from party C are shown in Fig. 18 and from party D in Fig. 19. No data on the bars from F were available. These photographs cannot, of course, all be in focus, as the fractures are too irregular. It is important to note the importance of good illumination for the microscopic examination. Sometimes diffused sunlight, at other times a strong daylight lamp is the best, depending on the color of the slag. As high a magnification as 80 is ordinarily necessary, but it sometimes happens that the slag can be seen with the naked eye.

Micrographic Examination

The microstructure of some of the bars in Table I was examined carefully. We could suspect the banded structure of the light and dark sorbite with Widmanstättian lines shown in Figs. 22 and 23 to be the cause of the poor result of test bar 720 BT2O, but we find a similar structure in the good bar 873 BT6M (Figs. 24 and 25) and less distinctly in 895 MT6M, both of which have a good cup fracture. The microstructure in Fig. 26 of Sample No. 107, with the rather surprising physical test of elastic limit 80,000, tensile strength 95,500, elongation 23 per cent, reduction in area 69

per cent, showing ferrite and pearlite banding, will give an explanation as to the origin of sorbite banding; it is simply that the heat treatment has not brought the solid solution to a condition of homogeneity.

Fractures of some nickel steel test bars from party D were now examined and the results given in Table III. The "flakes" in these fractures (shown in Fig. 2) are larger and more coarsely crystalline, with a leafy aspect instead of with a radiating fine grain as most of those in Table I. Some of the worst fractures can hardly be explained by the small amount of slag inclusions, as can be seen from a study of the table. The microstructure of D6 at the intersection between the flake and a plane meeting at a blunt angle (such as in Fig. 9) shows fine uniform sorbite, and a very small patch of Widmanstättian structure was all that could be found, this occurring at some distance back of the intersection. Evidently Widmanstättian structure could not have caused the flake in this case.

Internal Cracks

With but little slag in the fracture and no abnormalities in the microscopic appearance, the cause of these defective fractures remained undecided until more nickel steel bars from party E were obtained. These are listed in Table IV. The fracture of bar No. 681 shows a crystalline "snowflake," and No. 230 a crystalline fracture coated with oxide, evidently formed in a crack in the steel, probably in the heat-treating furnace or during forging. The microstructure of 681 (cut at a slight angle with the flake) is shown in Fig. 27, the microstructure of 230 (cut perpendicularly to flake) in

TABLE II—TABULATION OF CHARACTERISTICS OF FRACTURES FROM FORGING 843

Test Bar Mark	Physical Properties: Elastic Limit	Ultimate Strength	Elongation	Reduction in Area	Analysis: C	Mn	Si	S	P	Ni	Cr	Description of Fracture

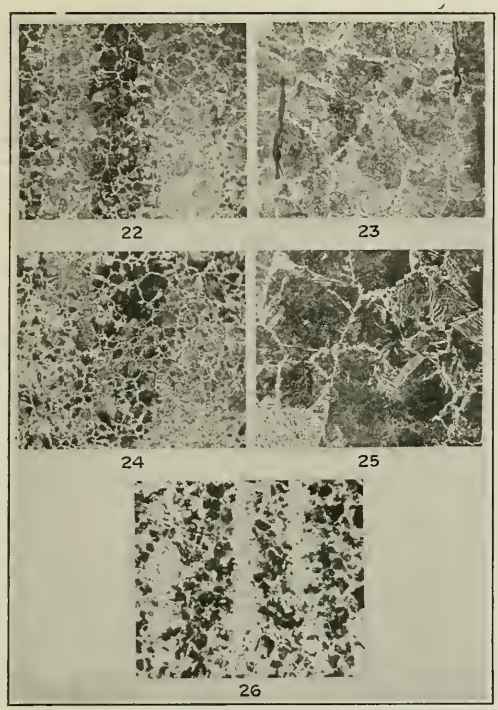
5943 BT1I	61,000	94,500	10.5	16 6	0 40	0 57	0 22	0 030	0 046	3.22	. .	One-fifth area a bright spot whose center is coarsely crystalline and white. Radiating structure from here to adjoining angular fracture. No inclusions.



FIGS. 22 TO 26.

Fig. 22. Banded sorbite in defective bar 720 BT2O, from party B. HNO_3 etching. × 25. Fig. 23. Same as Fig. 22. × 100. Fig. 24. Banded sorbite in accepted bar 872 BT6M, from party B. HNO_3 etching. × 25. Fig. 25. Same as Fig. 24. × 100. Fig. 26. Non-homogeneity in 107 from party B. HNO_3 etching. × 50.

Fig. 28, the latter showing a crack in a fine sorbite-structure and with no slag; a nearby crack, however, passed through small slag particles.

It seemed possible, therefore, that the cause of these flakes could be the cracking or incipient cracking of the steel previous to testing. To further illustrate this question a cold-broken part of a gun-tubing from party C shown in Fig. 29 was examined. Round coarse-crystalline "snowflakes" are here found separated by fibrous structure. Transverse (a — a) and longitudinal (b — b) sections of this broken part were polished and etched with the Stead-Le Chatelier reagent, and are shown in Figs. 30 and 31. There is no difference in the microstructure near the snowflakes and near the fibers, nor did the microstructure show any difference. In the longitudinal section (Fig. 31) it can be plainly seen how the dendrites run straight across the crater of a "snowflake." On its side the crater showed evident shearing.

Etching this tube a long time in strong acid revealed deep seated, fine cracks, running approximately radially and in the direction of the forging. Microscopic examinations of this sample as well as of samples 3 and 6 from party D and 681 from party E show no relation between the grain-size of the flaky fracture and the ferrite network of the microstructure. In sample 6 there is hardly any network visible, and 230 has none at all (Fig. 28). Where ferrite network was found, the grains exhibited in the fracture were much coarser than those in the crystalline network, so the crack or fracture must have gone through two or more crystals, irrespective of grain boundaries.

It is known that acid etching of forgings very often reveals deep cracks which may cause flakes; but often flaky test bars are found in sections where no cracks are found on etching. It is of interest to find whether a difference in structure would be the cause for the etching cracks. The author has made a few tests on deep etching for cracks which was done after the specimens had been carefully polished and lightly etched for development of microstructure. He has not found, so far, that the acid produces cracks where none were found in the microstructure. Where slag particles were situated, however, the acid generally left deeper etching pits, which is natural, because the acid gets a larger surface to attack after the acid has dissolved the slag, either directly or by dissolving the material around it. It seems, therefore, reasonable to assume that the cracks noted in the examination of flaky bars are present in the forging; they may have been original cracks in the ingot, or may have been formed in the subsequent heating and forging.

Kilby[1] has shown that improper pouring or pouring at too high or too low temperatures will cause cracking in the ingot. But there has been an endless discussion about the influence of the mold on the cracking and about which form of mold best will prevent cracking. To the author the main reason for cracking seems clear, considering the fact on which Driessen[2] has given numerical data, that steel, cooling and contracting from high temperature, has a period of expansion corresponding to the transition range. When the ingot cools, the outside layers will have expanded while the inner is still hot, and be less ductile when the interior layers expand, whereby the surface may start to crack. The author has noticed such cracking proceeding several days after the casting of large ingots. It is natural that it should start where the outer cold skin is the thinnest—for instance in the grooves of fluted ingots and in the sides of squares and polygons. On the other hand, the columnar structure of the surface layers might induce cracks leading in from the corners, because the weakest planes are to be found where the columns from different directions intersect, and where we also find most of the segregated impurities. Surface cracks must, however, be coated with oxides and are not the same as cracks in the inner parts of the steel, which on fracture are perfectly shiny and crystalline. Such cracks must have been formed by improper heating or forging whereby the surface has been stretched more than the inside can follow, or they may have their origin in blowholes which are not completely welded.

Blowholes and Forging Flaws

A sample of such unwelded blowhole in a fractured test piece is shown in Fig. 9, where the smooth shining surface of the flake leaves no doubt as to its nature. The polished section cut through the blowhole did not show any difference in microstructure of the flake and the material back of it, all being sorbitic. That blowholes do not necessarily weld at high temperatures can easily be shown by "forging" molding wax in which holes are made.

It is an absolute necessity that the surfaces touch

[1] *Journal*, Iron & Steel Institute, 1917, Vol. II, p. 69; *Engineering*, 1918, p. 34.

[2] *Ferrum*, Vol. II, p. 129.

when they are to be welded, and holes do not close before a certain reduction is performed. The temperature must, besides, be sufficiently high for welding, as shown by Stead[3].

A sample from soft steel used in a demonstration of improper hot forging practice was kindly furnished the author by J. S. Taylor of the Carnegie Institute of Technology and is shown in Figs. 32 and 33. The cracks have their principal direction radially, which is natural since the strain that has produced them goes at right angles to the direction of blows of the hammer or press when flat dies are used. It is clear that slag inclusions when forged will help to start such cracks, because they leave sharp angles in the strained material.

Flakes in Carbon Steels

In the examination so far made on nickel steels, I have practically always found slag inclusions associated with the flakes. It was considered probable that such inclusions would have the same effect on ordinary carbon steels, where the more scant occurrence of flakes must partly be ascribed to the fact that test bars are more generally longitudinal and seldom transverse for these types of steel. The larger section of a slag particle flattened in the direction of work and the sharp angle it cuts in the steel matrix must naturally show a greater effect in the results of testing transverse pieces.

With the interested help of party F, such transverse tests were made of different carbon steels with some corresponding longitudinal tests, and the results given in Tables V and VI. The flakes in these bars are more variable and are shown in Figs. 4 to 9 inclusive. The flaky test pieces showing the poorest physical properties are those containing large masses of slag (No. 210 P and 55), the slag showing up as round spots in the longitudinal tests (Fig. 20) and as streaks in the transverse (Fig. 21). The microstructures (Figs. 34 and 35) of cuts transversely and longitudinally through a fibrous flake show how the slag is arranged in light-colored streaks following the fibers. Fig. 36 gives microstructure containing many slag inclusions found near the peculiar spherical crater in 3070 (Fig. 7). The tests of greatest interest in Table VI are, perhaps, those of the two bars marked 3872 F, cut from adjacent parts of the forging, one giving a good test and the other a rotted fracture, breaking under the head along a crack which was declared by party F to be caused by cracking in quenching. Examination of these fractures shown in Figs. 5 and 6 revealed the presence of dark iridescent inclusions, and a microphotograph of the fracture-edge (Fig. 37) shows a decarbonized area filled with holes from which MnS had been dissolved by sodium-picrate[4].

We have exhibited in Table VI the effects of another variant of flake illustrated in Fig. 4 and characterized by a smooth round shining silky spot not connected

T 2-5050	50,520	83,620	20.5	34 3								Quenched at 1550, drawn at 1220. Several small dark inclusions.
R1X	64,400	82,620	18 5	27 5								Quenched at 1550, drawn at 1250. Tenth of area is fibrous flake with several yellow inclusions. Balance crystalline with two or three slag particles.
R 2X	68,900	87,120	25 0	37 3	0 44	0 71	0.20	0 041	0 048	.		Some scattered traces.
R1Y	63,650	81,520	20 5	22 4								Quenched at 1550, drawn at 1250. Half area is fibrous flake with many greenish inclusions. None in crystalline part of fracture.
R 2Y	70,680	85,720	22.5	38 8	0 45	0 61	0.23	0.032	0.049	....	.. .	Some small greenish inclusions, several scattered small dark dots.

TABLE VI—LONGITUDINAL TESTS OF CARBON STEEL BARS FROM PARTY F

Test Bar Mark	Physical Properties: Elastic Limit	Ultimate Strength	Elongation	Reduction in Area	Analysis: C	Mn	Si	S	P	Description of Fracture
199 P	36,240	67,640	28 0	36 4	0 27	0 52	0 20	0 032	0 052	Annealed. A few light green inclusions in bright spots. Small dark spots scattered over surface.
202 P	36,840	69,050	27.5	33.5	0.26	0.48	0.20	0.033	0.047	Annealed, two or three round yellow inclusions. Small dark spots scattered over surface.
210 P	35,940	66,560	33 0	48 5	0 26	0 46	0.17	0 030	0 051	Annealed. Some large, round, yellow inclusions in bright spots and small holes between.
3872 F	51,580	73,980	0 0	0 0	0 45	0 76	0 23	0 032	0 048	Annealed. Irregularly cracked fracture with bluish dark inclusions along crack.
3872 FF	53,160	82,620	27 0	50 6						Small scattered holes and two or three small bright spots. No inclusions.
234I	36,420	67,060	10.5	19 9	0 28	0 42	0 14	0 036	0 054	Annealed. A smooth, velvety bright spot. Small scattered dark inclusions.
234II	33,220	64,660	12.5	32 0						A smooth, velvety bright spot.
3070 D	59,460	91,880	16.0	27 5	0 44	0 71	0 22	0 032	0.047	Water quenched and drawn. A spherical flaw, crystalline in center, dark irregularities on sides; perhaps dots of MnS.
M 53D	....	....	..	....	0 47	0 71	0 18	0 034	0 043	Heated in 11 hrs. to 1500; held 8 hrs.; heated in 2 hrs.; to 1600; held 2 hrs.; quenched in water; drawn to 1250 in 8 hr., held 6 hrs.; air cooled. Fracture showed angular flow, smooth and shining; probably side of an unwelded blowhole.

TABLE VII—CARBON STEEL BARS FROM PARTY G

Test Bar Mark	Physical Properties: Elastic Limit	Ultimate Strength	Elongation	Reduction in Area	Analysis: C	Mn	Si	S	P	Description of Fracture
1642-2	48,050	83,000	19 5	17 8	0 47	0 59	0 20	0 033	0 046	Whole fracture fibrous. Some dusty, thin, dark inclusions. Many traces.
1642-4	50,970	89,400	19 0	20 3						Whole fracture fibrous. Some thin dark streaks. Many traces.
2536-2	54,700	100,700	10 0	10 1						Three-fifths fracture fibrous with many shining dark slag streaks.
2536-3	53,280	96,140	10 0	10 0	0 50	0 55	0 26	0 052	0 035	Half fracture fibrous with many shining dark inclusions. A few small inclusions in crystalline part.
2536-4	55,260	101,900	12 0	13.4						Half fracture fibrous with many dark slag streaks.
2649-4	52,060	102,500	14 0	14 2						Half fracture fibrous with shining dark slag streaks.
2808-3	54,000	90,800	5.0	4 3	0 55	0 58	0 22	0 046	0.036	Third fracture fibrous with many dark shining slag streaks.
2856-2	50,330	93,760	20 5	25 9	0 46	0 68	0 24	0 037	0 039	Fracture irregularly fibrous, short dark streaky inclusions.
2856-3	50,880	96,700	17.5	28 9						Fracture irregularly fibrous, thin dark slag streaks.
2788-2	43,860	82,200	22.5	32 3						Fracture slightly fibrous. Some traces.
2788-3	44,230	85,000	19 5	24 9	0 55	0 58	0 22	0 050	0.036	Fracture fibrous. Some streaks of slag.
2788-4	49,060	87,400	17.5	26 2						Irregularly fibrous with small slag streaks.
2618-2	53,940	105,200	14.0	16 0	0 57	0 61	0 24	0 048	0 042	One-fifth fracture fibrous. Larger patches of shining slag.
2393-2	43,550	80,500	13.5	19.8						Laminated fracture. Large and small dusty steel gray inclusions.
2393-3	43,880	81,400	8 0	12 0	0 55	0 61	0 26	0 052	0 035	Half laminated fracture containing dusty steel gray inclusions.
2399-2	53,880	60,500	0 0	2 0						Bad fibrous flake. Irregular fracture.
2164-2	59,200	107,950	17.5	34 7						No lamination. Very short, dark traces at angle with fracture.
2164-3	63,050	107,700	7 0	6 3	0 52	0 52	0 22	0 047	0 034	One-tenth fibrous, filled with shining traces and dark slag streaks.
2164-43	62,050	105,400	7.0	8.4						One-fifth area at edge laminated, containing shining irregular traces and many thin dark inclusions.
2301-2	52,720	97,700	14 1	16.5						Half laminated. Traces, a dark slag streak, and some green inclusions.
2301-3	51,950	98,100	16 5	19 2	0 52	0 70	0 22	0 047	0 030	One-third fibrous. Shining traces and some tiny inclusions.
2301-4	53,200	100,950	17.0	26 8						Two-thirds fibrous. Shining traces and some slag streaks.

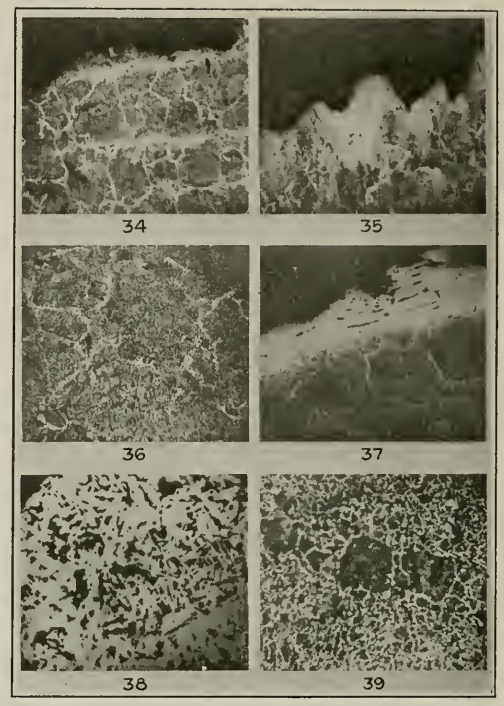
with large slag particles, but where possibly small dots of MnS are present. On cutting through this spot and examining the microstructure of the bright edge a somewhat heavier line of ferrite was found to accompany the fracture. Fig. 38 shows this structure a little back of the flake, giving the distribution of smaller grains within the larger primary crystal, which nearly outlines the picture and which is caused by heating to high temperatures.

Examination of transverse bars of higher carbon content from party G are given in Table VII. All the flakes here are of the fibrous type (Fig. 3). The slag inclusions—nearly all glossy, dark streaks—are almost exclusively in the fibrous part of the fracture. They are, as a rule, very thin, but where they are easily distinguishable the physical tests are lower. There is one peculiarity in these tests, namely, that in tests where only part of the fracture is fibrous, the elastic limit and tensile strength are higher, but the elongation and reduction in area are lower than in fractures where it is entirely fibrous, which may be explained



FIGS. 34 TO 39

by a higher ductility of the fibrous than of the non-fibrous material. The fibrous part would yield earlier and act as a notch to fracture the rest of the bar. Sample 2379 from party G differs from the rest in that it shows phosphorus segregation with a large grain formation in a cut parallel to the fibers (Fig. 39), and these segregations can easily explain the presence of a fibrous fracture. There was also a noticeable difference in the tests of 2164 2, 3 and 4 which were taken out of the forging a couple of inches apart and parallel to one another. All had the same microstructure. Examination of the fractures showed a few small "traces"[5] in No. 2 apparently from slag protruding at an angle with the fracture; in 3 and 4, however, there were more particles which were parallel to the fracture. A section was cut through the bars parallel to the direction of forging and etched with Stead's reagent, with the result that 4 showed a much stronger phosphorus segregation than 2.

Dendritic Structure

This brought up the question whether the fibers were caused primarily by phosphorus segregation of the dendrites or whether slag streaks must be present for the formation of fibers. Several samples of cup fractures, one from party C with fibers and slag traces and two others from party B with cup fractures and no traces or fibers, were then cut parallel to the direction of work and the microstructure developed as shown in Fig. 40 (bar from C in middle). Where no slag streaks are present, fibers do not show up on pulling the bar transversely. Etching for transverse dendrites in laminated and cut fractures in Ni steel, from party A (Fig. 41), shows no difference.

Another possible cause for flake may be segregated spots such as are exhibited by the variable-hued grains in Fig. 23. Hard spots are very often found in steel and are mostly phosphorus segregations, or they may be caused by incomplete solution of ferromanganese[6].

Summary

From the foregoing the author has endeavored to show that the predominant cause for flakes is slag inclusions. They may less often be caused by cracks formed by faulty mill practice, by blowholes or segregations. No distinct microstructure is found associated with flakes; therefore in general heat treatment is powerless to cure them.

In a subsequent communication the correct furnace practice to follow to reduce slag inclusions to a minimum will be discussed, which procedure has in practice largely reduced the rejections in plants which have adopted it.

Carnegie Institute of Technology,
Pittsburgh, Pa.

[5] As previously noted, "traces" are shiny smooth spots from which slag particles have fallen.

Melting Points of Chemical Elements, and Other Standard Temperatures

THE following table of melting points of the chemical elements is issued by the Bureau of Standards in answer to numerous requests for this information:

The values of the melting points used by the Bureau as standard temperatures for the calibration of thermometers and pyrometers are indicated in capitals. The other values have been assigned after a careful survey of all the available data.

As nearly as may be, all values, in particular the standard points, have been reduced to a common scale, the thermodynamic scale. For high temperatures, and for use with optical pyrometers, this scale is satisfied very exactly by taking $c_2 = 14\,350$ in the formula for Wien's law connecting $I\lambda$ monochromatic luminous intensity of wave length λ, and T, absolute temperature: $I_\lambda = c_1\lambda^{-5}e'^{\frac{c_2}{\lambda T}}$. For all purposes, except the most accurate investigations, the thermodynamic scale is identical with any of the gas scales.

At high temperatures some of the values are quite uncertain; thus, while the melting point of platinum may be considered accurately known to 10 deg. C., that of tungsten is possibly uncertain by 50 deg. C. or more. Temperatures Centigrade are rounded off, and the exact Fahrenheit equivalents are usually given.

Solid Rubber Tires

History of Solid Rubber Tire Development, Sidewire and Wired-on Types—Bands—Hard Rubber Base, Methods of Applying and Quality of Stock—Calendered and Tubed Treads, Manufacturing Processes and Comparison of Tires—Testing of Solid Tires, Specifications

By ANDREW H. KING

THE USE of solid rubber tires depends on two main characteristics. First and foremost, they tend to equalize road surfaces, protecting both vehicle and rider from shock. In this a solid tire is very inferior to the pneumatic. Rubber cannot be compressed. It can only be deformed and to an extent dependent on the degree of loading of the stock. Solid tires are heavily loaded. By this I mean that more than 30 per cent of the volume of the tire is something other than rubber. In present practice zinc oxide, or lampblack, or both are chiefly used. The normal elasticity of rubber is greatly reduced. On the other hand a pneumatic tire depends on rubber and fabric only to provide the container for the true carrier, which is air under pressure. In common with other gases it is approximately perfectly elastic. It can be compressed at will. For this reason it provides the ideal cushion. However, solid tires are unquestionably greatly superior to a steel band, and their introduction during the early '80s for carriages was indeed a great step.

The second function did not develop until after motor-driven vehicles were introduced, when they were required to provide traction. This brought about a widening of the tire and a decrease in its diameter. From this standpoint the solid tire is satisfactory as long as it is kept on good roads. It is useless in mud, or on wet, slippery asphalt paving.

Solid vs. Pneumatic Tires

As is well known, the solid rubber tire was first introduced for carriages. Then followed the advent of the automobile with its greater speed, when the pneumatic tire largely replaced it for pleasure vehicles. But the development of the motor truck has given it a new lease on life. Here pneumatics in large size were until the past year or so unavailable. Even yet they are more expensive, liable to puncture, and not wholly satisfactory. The solid tire is dependable, it lasts a long time, and can carry a high overload for a short distance without danger. One prominent exponent of pneumatic truck tires is confident that history will repeat itself and that the solid truck tire will eventually give way to the pneumatic. Perhaps he is right, but for some years to come the manufacture of solid tires will continue.

There is no great certainty as to when solid rubber tires were first introduced, but we do know that their use was nowhere general until they were applied to the extensive line of hansom cabs operated in London in the early '80s by the Shewsbury & Talbot Noiseless Tire & Cab Co. Their tire had been invented by Carmont, whose patents were granted in 1881 and 1883. By the original definition, it was a rubber tire held in a rolled steel channel in a state of compression between converging flanges.

Fastening to the Wheel a Problem

It is well to digress at this point and to note that the great difficulty in tire design was not to provide a stock which would stand up well under the conditions of service, but the problem was how to fasten such a tire to the wheel. For Carmont's purposes compression in a steel channel was sufficient. But by so doing he decreased the readiness with which his tire was deformed. It was hard, and except for being noiseless was little better than the steel band.

The logical advance from this stage was, of course, to the "wired-on" type. Grant[1] held his tire in place by means of longitudinal wires, two at first and more for larger sizes. His channels were not as deep as those of Carmont. More rubber was exposed for wear, and as there was no compression the tire had greater resiliency.

The Burgess tire was similar to the Carmont except that he introduced longitudinal wires which had been wrapped with small special wires for the protection of the rubber. The Victor tire was similar to Grant's, but the wires were encased in leather.

Many Types Designed

Easier of application, but similar in principle, was the "sidewire type," known also as the Firestone and as the Swinehart & Byrider[2], who were the patentees. It was held in place by two endless retaining wires which were sprung over the edges of the channel and engaged the ends of embedded cross wires or bars. In this way the tire was held securely in place.

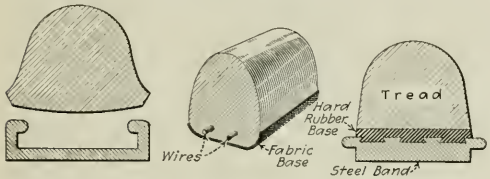
The various "wired-on" types are reasonably satisfactory in sizes up to 2¾ in. in width; i.e., for buggies, carriages, victorias, etc., where the tire is not required to transmit traction. In larger sizes and where "traction" must be furnished, the strain on the stock next the retaining wires causes tearing, which ultimately throws the tire. This difficulty led to the development of many very ingenious designs. The splice which proved such a difficulty in the "wired-on" type was eliminated. The new tire was endless, i.e., spliced, and fastened in the uncured condition to a special band which was so designed as to be easily mounted on the wheel, usually by removing a flange which when bolted in place held the tire securely.

No mechanical method of fastening the tire to the band proved satisfactory. Wires, steel rods, bands, etc., no matter how complicated, all cut or tore the tire when

[1] U. S. Pat. 554,675, 1896.
[2] U. S. Pat. 686,556, 1901.

placed under strain. The solution of the problem was very simple, and was developed in Germany by the Metzler Co. They dispensed with all wires, hooks, etc., and interposed between the steel band and the tire a hard rubber base which securely united them. To strengthen the union to the band they introduced an ingenious system of dovetailing. In this way no local strain was placed on the tire, the load being taken uniformly by the whole base of the tread. This type of tire has now come to be accepted as the standard form.

There are two ways of fastening such a tire to the wheel. For the smaller sizes (3 to 5 in. in width) bolts and flanges are satisfactory. For larger widths the traction is too great and a larger number of bolts are necessary for secure fastening. To combat this



FIGS. 1, 2 AND 3. ON LEFT, SECTION OF CARMONT'S TIRE. IN CENTER, GRANT'S TIRE—STANDARD AMERICAN CARRIAGE TIRE. ON RIGHT, METZLER'S TIRE

trouble the "pressed-on" type was developed. The band is forced on the wheel by hydraulic pressure. It is placed under considerable tension, which effectually prevents any creeping of the tire on the wheel. At the present writing very few bolted-on tires are made. The pressed-on tire with a hard rubber base is apparently the last word in solid tire design.

Solid tires may be classified in three broad divisions, namely, carriage, truck and cushion. The essential details of manufacture are outlined below.

Carriage Tires

The chief demand for rubber tired carriages is found today in certain parts of the South, Canada and South America, regions where the "flivver" is as yet unknown or impossible because of bad roads.

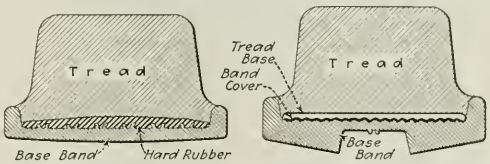
Carriage tires are shipped to the various wagon shops in reels of variable lengths and in widths running from ½ to 2¾ in., depending considerably on the purpose for which the tire is intended. Under this head is included the cheap grade which is made in small sizes for invalid chairs, etc.

Stock: The compound employed will vary with the severity of the service. The chief considerations are price, specific gravity, body, strength, easy working, a certain degree of hardness, and a reasonable "give." To keep the cost down very little rubber is used. Shoddies are quite satisfactory. The "body," or, expressed differently, the degree of loading, is very important. To tube nicely the stock must be firm but not too soft and never very sticky. The proper balance of these qualities is unfortunately only learned by experience, and is almost impossible to describe. The curing agents must be carefully chosen. The accelerator must not be high powered or it will be liable to cure the stock in the tube machine. A common fault with many carriage tires is slight blowing which is indicative of an unbalanced formula or an insufficient quantity of stock in the mold, thus preventing proper pressure on the tire during curing.

Milling and Warming Up: Many carriage tire formulas give a batch which is difficult to handle on the mills. There is little if any rubber to hold it together and frequently asphaltic or other sticky material will be present in quantity. For the poorer grades a scraper attachment is absolutely necessary, as the stock cannot be batched off by the mill man. The scraper is a knife 6 to 8 in. wide fastened to the end of a lever, the fulcrum of which can be slid back and forth in a direction parallel to the length of the rolls. When the batch leaves the mills it is in ideal state for tubing. It is soft, plastic, and will take almost any shape imposed. But no tube machine can be operated efficiently without a supply of stock on hand. Therefore it is necessary to install a warming up mill in close proximity to the tube machine.

The Tube Machine

Tubing: The tube machine is designed and operated on the same principle as the old-fashioned sausage grinder and stuffer. Pieces of warmed stock, cut to convenient size, are fed by hand. A worm which operates in a casing carries it forward, packing the stock tightly together all the while. At the end of the worm it enters a sleeve which reduces it in diameter, and then passes through a die. Except for being power driven and stronger and heavier it is exactly like a sausage machine. Since shoddies frequently contain pieces of metal, a wire screen is sometimes placed in the sleeve to intercept them. The internal wire holes of the "wired on" tires are made by attaching to either the die or the carrier two metal forks which project through the opening. As the stock passes beyond the die the compression is removed and the holes remain intact. Considerable experience is required in adjusting the temperature of the die, which is regulated by a skilled operator with an ordinary bunsen burner. As all stocks do not tube well at the same temperature,



FIGS. 4 AND 5. SECTIONS OF STANDARD SOLID TIRES. ON LEFT, "PRESSED-ON" TYPE, ONE HARD RUBBER. ON RIGHT, "BOLTED-ON" TYPE, TWO HARD RUBBERS

no little experimenting is required before the best conditions are arrived at. The casing is jacketed and is provided with means for heating and cooling similar to the ordinary mill. As the tire leaves the tube machine it passes first through powdered soapstone and then through revolving brushes which remove the excess. At this point it is picked up by a conveyor belt traveling at slow speed. When the desired length is attained, which depends solely on the length of the heaters, the operator cuts it off and throws it into a tray, after which soapstone is blown through the wire holes.

Cheap tires, such as the poorer grades of baby carriage tires, are not handled quite in this manner. As

the tire comes from the tube machine it is coiled up on a circular rotating board. When the board is full the tires are dusted with soapstone. Such tires are not infrequently given an "open steam" cure. The board is covered with a layer of soapstone an inch or more in depth and put directly in the heater without any wrapping whatever. The procedure is not very satisfactory, but is sufficient for the quality of goods produced.

Wiring: Wires of the proper size are inserted in the holes in rather a clever manner. The nozzle of a compressed air line is pressed tightly against the holes at the opposite end from which the wires are to be inserted. The holes are slightly distended when the wires are started through, thus allowing them to slide in on a cushion of air.

Curing: Only a small portion of the annual carriage tire production is cured under hydraulic pressure. Us-

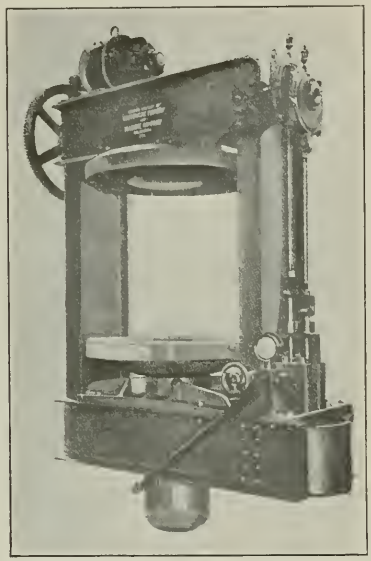


FIG. 6. 200-TON PRESS FOR FORCING SOLID TIRES ON OR OFF WHEELS

ually full dependence is placed on a series of bolts which are tightened down by the heater men. The heaters are quite long, varying from 20 to 50 ft. in length, and consist essentially of two steam heated platens. The steel molds are detachable, so that the same heater may be used for curing tires of various widths. At each end of the platen are spaces a foot or more in length, which are spoken of as "dead" or "cold" ends. As will be seen later, they are very convenient in splicing the successive lengths into a long reel.

The Usual Curing Procedure

The usual curing procedure is as follows: The wired lengths are placed in the mold face down. The bases are scrubbed with gasoline to remove the soapstone, then given a coat of cement, and the tape, frictioned on one side, is applied. The fabric backing gives the tire a longer life. This length is spliced to the preceding one as follows: It projects, let us say, one foot into the left "dead end," which brings it a foot from the right "dead end," on which side the reel is located. The uncured end of the previous length is hauled down, the ends of both tires cemented and joined together. The tape is carried six inches or a foot beyond the splice. This leaves a section of the cured portion in the right "dead end." Some presses are designed with only the left "dead end," but they are not quite as satisfactory as those described above. The top platen, which is raised and lowered by a chain block, usually electrically driven, is set in place and bolted down.

When the period of vulcanization is completed the first step is to remove the wires, which is sometimes very difficult. The operator grasps the end of the wire with a special set of forceps which are designed so as to give him a firm hold and a long leverage. He twists and turns the wire until it is loose in its cavity. By applying compressed air at the end of the reel as before, the wire is drawn out without further trouble. Wires which have been in constant use for some time require an occasional bath in caustic soda to clean them.

The tire is trimmed by passing between two revolving knives, which remove the "rind." The lengths are measured, weighed, and wound on reels, when they are ready for shipment.

Applying Tire to Wheel

Application: The method of applying such a tire to the wheel is interesting. Special apparatus, of which there are numerous designs, is required. Three things must be done simultaneously. The wheel must be firmly held so as not to rotate, the wires must be placed under tension, and the tire itself must be compressed, i.e., slid back from the splice a distance of at least eight inches. Then the wires are brazed together. The ends of the tire are cleaned with solvent, given a coat of cement, and acid cured by brushing a little sulphur chloride solution over the cemented ends and bringing them quickly together.

Carriage tires must stand up on all kinds of rocky, muddy and sandy roads. They must have great resistance to abrasion and must age well. The old carriage tire man put a suitable product on the market long before the era of testing machines. He depended upon a few simple tests which are worthy of brief mention.

Slice Tests: By snapping a thin slice cut perpendicular to base of the tire but not quite to the wire holes one is able to judge very closely as to the spring, elasticity and cure of the tire. The force required to pull this piece off gives a measure of the tensile strength of the stock.

Tread tearing: The face of the tire is cut back at a small angle so as to give a hand hold. Pressure is then applied to separate tread from base. The force required furnishes an index as to the wearing value of the compound.

Twisting: One should be able to twist a good tire a number of times, and find on releasing that it regains almost completely its original shape. Many cheap tires are so loaded with asphaltic material that they appear dead and lifeless. They do not even approach their original shape.

Bending: The surface of the tire should show no

checking or cracking when bent through 180 deg. and the surface scratched with the back of a knife or the finger nail.

Hardness: If the point of a pencil is pressed straight down into the tire the pressure required is an index of the hardness, and the rate of recovery shows the nature of the stock.

The tensile strength of carriage tire stocks usually varies from 700 to 1200 lb. per sq.in. The stretch runs from 200 to 350 per cent. The set (Bureau of Standards method) is from 15 to 35 per cent.

The life of a good tire is very long. This is partly due to the intermittent service it receives, and partly to the light loads carried.

Truck Tires

As indicated above, practically all truck tires are built on steel bands which are either bolted on or pressed on to the wheel. Pressed-on tires make up a very high percentage of the total output. Except for slight variation in the design of the band, there is no difference between the two types, and they will be considered together without further mention. The essential parts of the tire are: The band, hard rubber base, and the tread. They will be considered in order.

Bands: They are of mild steel corrugated and rolled to the desired width and design at the mill, and are usually delivered to the manufacturer in long lengths. He then bends them to the desired diameter and welds the splice, usually with electric welders. Before the bands are ready for covering they must be sand-blasted to remove any rust. Blasting also slightly roughens the surface, which causes the band cover to stick much better.

Hard Rubber Base: This is beyond question the critical part of the tire, and that on which its success is largely dependent. Several manufacturers have recently learned to their sorrow that poor hard rubber ruins a tire. If it does not cure up properly, or if it does not stick well to both band and tread, they will separate. This is the end of the tire regardless of how good the tread may be. Union to either band or tread is fairly easy, but to both is quite difficult. The presence of corrugations and uneven grooves in the band allow a softer hard rubber to be used as they increase the union. This is perhaps the poorest solution to the problem, but many good tires are made after this fashion.

One or two makers of tires do not depend on just one hard rubber. They use two. The band cover, i.e., the one in contact with the band, is completely cured up and sticks to it very well. On top of this is the tread base, which is a semi-hard rubber. It sticks well to both band cover and tread.

Applying the Band Cover

This is perhaps the best scheme, though it must be more expensive. In either case the first step is to apply the band cover. The sand-blasted band is placed on a revolving spider or chuck. A number of spiders are mounted in a long row. Each one is belt-driven from a shaft overhead, but is fitted with a clutch so that it may be started and stopped at will. The band surface is cleaned first with wire brushes to remove any sand or scale and then with gasoline or benzol to remove any grease. The solvent used must be free from grease and sufficiently volatile so that none remains a few minutes after washing. The green stock is milled, calendered, and cut into proper width and length in the usual manner. The end of strip is pressed down on the band with care that it is in proper alignment. The band is started slowly and the stock pressed down with a wide flat roller. Then the speed is increased and a narrow stitcher is used. This presses the stock tightly into the grooves. Where any individual design is to be given to the hard rubber a special roller is used to finish it. Next the surface is washed well with solvent

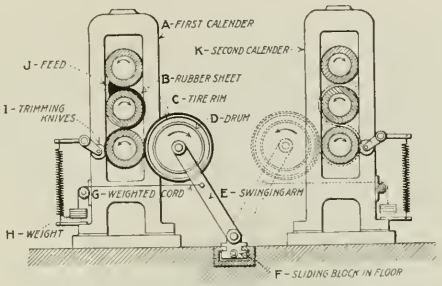

FIG. 7. GRAY'S APPARATUS FOR CALENDERING SOLID TIRES

and allowed to dry. If there is only one hard rubber to be used, the band is now ready for the tread. Tread base procedure will be described later.

Tread: Formerly most treads were made up of two or even three different types of stock. But this has now been practically abandoned and only one kind is used for the tread. There are two general methods by which the tread is prepared, i.e., calendering and tubing. The former will be considered first.

Calendered Tread

The steps here are as follows:

Filling the Band: The covered band (i.e., covered with hard rubber) must be filled with tread stock to a little past the edges of the channel. Filling is usually done by hand, using strips of calendered stock.

Treading: The filled band is placed on a special apparatus for holding it against the lower roll of the calender. Two designs are indicated in the accompanying sketches. Fig. 7 is representative of old practice when more than one tread stock was used. The tire is built to a certain thickness on one calender and is then thrown over to the other calender, where the second tread is applied. This design is weak in that the pressure under which the stock winds up is not very great. Present practice is better. The tire is mounted on a chuck which is carried by the piston rod of a compressed air cylinder. With this apparatus the tire is built up under pressure. The plies stick together better and the tire lasts longer in service. When one tire is completed the apparatus is rotated. This brings another band into position.

Trimming: When the tire leaves the calender it is rectangular. It must be trimmed to the section of a trapezoid and if the size is 10 in. or over it must be grooved according to best practice. This is accomplished by placing it on a revolving chuck, rotating it at high speed and advancing a knife in a manner similar to the

handling of the cutting tool on a lathe. The grooving is done with a special spoon shaped knife.

Several manufacturers use the calender process for tires 10 in. or more in width, and many others make all sizes from 7 in. up in this way. For sizes in excess of 7 in. a very large tube machine is required, and the difficulties incident to handling so much stock efficiently are not small. There is said to be but little difference in cost between tubed and calendered tires, though the writer believes the latter has a shade the edge on the former.

Tubed Tread

The stock is prepared in the usual manner. It is customary to use two or even three warming up mills to keep the tube machine well supplied. It is similar in design to the one described under carriage tires, but is many times larger and stronger. The die gives the tire its approximate shape. There are two general procedures for handling such tires, known as the hot and cold methods respectively.

Hot Method: The tire as it comes from the machine is applied directly to the covered band, which has been placed on a revolving chuck close by. The proper length is cut off and the splice made with the hot stock. It

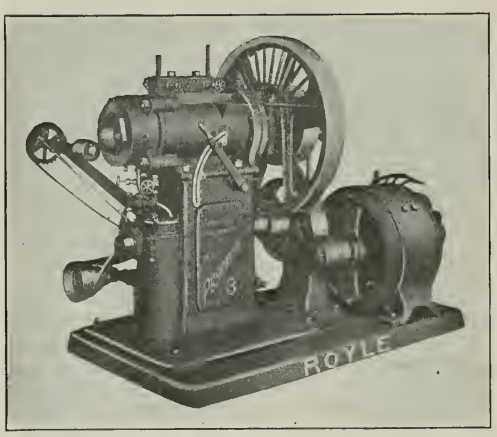

FIG. 8. TUBE MACHINE, SIZE SUITABLE FOR CARRIAGE TIRES

then goes to the power stitcher, where the thread is forced in close union with the hard rubber base. The power stitchers are two fair sized rollers, power operated. The lower roller supports the band and the top one is lowered by means of a screw so as to bring pressure to bear on the thread. After trimming off any stock which has been forced out the tire is ready for curing.

The hot method is quick, cheap and very efficient; but does not give entirely satisfactory unions, due perhaps to a semi-curing of the hard rubber.

Cold Method: Formerly all tires were tubes in single stick lengths just the same as carriage tires. But now several factories run a double stick and saw the two halves apart. This practice is, of course, impossible when tires are handled by the hot method, but for the one being described it is very appropriate. It is cheap, efficient, and produces a better tire.

Process by Cold Method

The double stick is picked up by a slow moving conveyor belt as it leaves the tube machine. When the proper length is reached it is cut off, rolled over on a board, weighed, and allowed to cool. When the stock shows a tendency to swell unevenly on cooling, it is often necessary to drop the stick into steel forms, where it remains until quite cold.

Sawing: The stick is cut into two treads by a rapidly moving band saw, the blade of which has very small teeth or none at all. A special feeding device is employed to hold the parts firmly and at the same time keep them separated. The design ordinarily used is a combination of a conveyor belt with a number of grooved rollers.

Tread Base: Where only one hard rubber is used, the tread goes direct to the building room, where it is spliced and placed on the band. Because of the value of the two-hard-rubber tire, we will take up now the tread base. As above mentioned, it is a semi-hard rubber designed to unite the tread and band cover. Milling and calendering of the stock is according to usual practice. It arrives in the applying room wound up in narrow reels.

The sawed treads are placed on a rack face down. The bases are washed well with either gasoline or benzol and allowed to dry in an atmosphere free from dust. When dry they are loaded on a conveyor, which delivers them to the rolling machine. This is a simple contrivance which increases the efficiency of the application. The reel of tread base is hung overhead and unwrapped as needed. When the conveyor delivers a fresh tread, the machine is stopped and the tread base firmly attached for about an inch, after which the work proceeds. The tread and base pass under a wide roller, which presses them firmly together, thus producing a very good union. As the tread comes out on the other side of the roller the edges are trimmed, usually with a V-shaped knife whose inner edges are sharpened. The stick is cut to proper length and receives its final weighing. The upper surface of the tread base requires washing to remove dust. Sometimes a coat of cement is necessary. When the stocks are dry and do not unite easily, it is usual practice to cement both tread and hard rubber regardless as to whether one or two stocks are in use.

Splicing Methods

Splice: There are two methods of cutting the stick for splicing. In some factories the cut is made square. This is known as a butt splice. The other and most usual form is the diagonal splice. The stock is cut at a 45 deg. angle so as to give longer joining surface.

The cut ends are washed with solvent, dried, and placed in the jammer. It consists of two clamps having wide knurled faces. One clamp is fixed, but the other is movable. Considerable force is applied by means of a fairly long lever, thus effectually pressing the ends together. The stock is held under pressure only a minute or so. The method is very good. The joint is stronger than the green stock anywhere else in the tire.

Application to Band: The tread is now a ring. The

band is placed on a circular table, which may be rotated. The ring is stretched and fitted over the band by means of rubber mallets and a set of three or more irons which are similar in shape to carpenters' wood chisels. Then the edges are stitched under the sides of the band with narrow steel stitchers. From the applying table the tire goes to the power stitcher, where the tread and hard rubber are pressed tightly together.

Curing

In the foregoing we have covered the principal variations in the preparation of "pressed-on" or "bolted-on" truck tires, bringing them all to the state when they are ready for curing.

All truck tires are cured in autoclave presses in heavy sectional cast iron molds. The heaters are set so that their upper edge is about 2 ft. above the floor of the pit, which is the name applied to the curing room. They are massively built. From twenty to thirty tires can be cured at one heat. This type of heater combines the advantages of press and open steam cure. The molds and tires are accurately heated throughout and the desired hydraulic pressure is applied at the same time. The lid of the heater is secured by bolts or by a system of slots. The latter form is now most in use. The lid drops in place and is locked by turning it a distance of about six inches. It serves as a backstop for the hydraulic ram, which is placed in the bottom of the heater. Pressure is transmitted through the molds to the lid.

Because of the extreme thickness of the stock to be vulcanized, a rising cure is absolutely necessary. The first stage is of short duration and low temperature. The second and third are progressively longer and at higher temperatures. Three raises are usually sufficient, but some of the very large truck tires require four. When the period is ended the steam and hydraulic are shut off, the heater drained, and the lid removed. Then it is filled with cold water to cool the molds sufficiently for handling. When cool, water pressure is applied to the ram and the load gradually raised. The molds are opened with bars and the parts carried off by chain blocks which run on an overhead trolley.

The tires are removed, trimmed and inspected. They are then ready for sale.

Comparison of Tubed and Calendered Tires

In a calendered tire the plies are wound up spirally. The grain is therefore circumferential. Maximum strength is in this direction. The tire is weakest across the grain. Tearing takes place with the grain, i.e., parallel to the circumference. The bond between the plies is comparatively weak. When a calendered tire fails in service it is usually because of ply separation or tearing with the grain.

When a tire is tubed in a single stick, the grain runs in concentric cones along an imaginary line through its center parallel to its length. Such tires develop in service peculiar looking tears and cuts, which of course follow the lines of the grain. When the tire is tubed in the double stick, the grain is in the same direction, but the ends are tied down to the hard rubber base, thus presenting a fairly uniform resistance to cutting, etc. However, when the stock is not of quite the right texture due to stiff crude rubbers, or for any reason such as when it does not receive proper compression in the tube machine, there is a distinct line of weakness along the grain and the tires develop herringbone breaks after a short time in service.

It is still an open question as to which is the better, calendered or tubed tires. The main objection to calendered tires is ply separation, and to tubed tires herringbone breaks.

Testing of Solid Tires

Notwithstanding the action of the Government in discontinuing the Barbecue test, the writer feels that this is the best way to obtain an accurate knowledge of the state of things within the tire.

Barbecue Test: The tire is placed in a vise and securely fastened. By means of a knife a long, slanting cut is made in such a way as to separate about 18 in. of tread. Around this a rope is looped, which is in turn

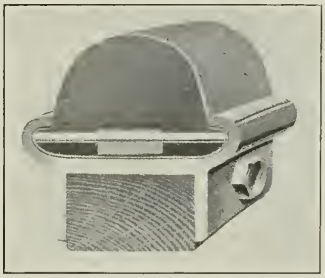

FIG. 9. SOFT-BASE TRUCK TIRE

fastened to a steel cable connected through a dynamometer to a chain block. A little tension is applied and the tread cut through, down to the hard rubber. Load is gradually increased and the trend union determined by the pounds pull required to separate it from the hard rubber. Former Government specifications required at least 100 lb. per inch of width. Thus a 6-in. tire was required to show a tread union of 600 lb. or more. As a matter of fact, the better grades of truck tires run much above this. Some go as high as 200 or even 300 lb. per inch of width.

The union of the hard rubber to the band is examined with a hammer and chisel. It should be so good that one can separate a piece of hard rubber within itself easier than it can be removed from the band. Where two hard rubbers are used, they should adhere so tightly that they cannot be separated. A section of tread is cut off squarely and placed in a slicing machine. It is similar in design to those used in butcher shops for slicing bacon, etc., but is much heavier and has a power drive. Both longitudinal and transverse sections are cut. Transverse slices are tested by the compounder for cure and feel. Regular tests for tensile strength, etc., are made on the others.

In view of Government specifications covering solid rubber tires the tendency has been for all makers to bring their product somewhere near the quality required. Therefore the following abstract of specification No. 1074-A may be taken as descriptive of American truck tire practice to-day.

1. *Rubber:* The compound shall contain not less than 65 per cent by volume best quality wild or plantation rubber. Shoddy or mineral rubber when used is to be in addition to this 65 per cent. Refined or ground vulcanized rubber is barred.

2. *Sulphur:* Not more than 8 per cent on the weight of crude rubber employed. This figure is plenty high.

3. *Saponifiable Matter:* Saponifiable oils or anything made from them are barred. This eliminates rubber substitutes.

4. *Tensile Strength:* They divide tires into two classes. (*a*) Those where the specific gravity is 1.40 or over (high zinc oxide) shall have a minimum tensile of 1800 lb. per sq.in. (*b*) Those having a specific gravity of under 1.40 (high lampblack) must have a minimum tensile of 2000 lb. per sq.in.

5. *Stretch:* Standard is placed at 350 per cent.

6. *Set:* Not over 40 per cent two minutes after rupture is maximum.

7. *Aging:* After heating two hours in an oven at 228 deg. F. the depreciation when tested 24 hr. later is to be not more than 35 per cent in elongation.

8. *Adhesion:* The tire is placed horizontally on the platen of a tire applying press, supporting it on a steel band having the same diameter as the base of the tire to be tested. On the upper side a band $\frac{3}{4}$ in. thick with an inside diameter $1\frac{1}{2}$ in. larger than the outside diameter of flange of base band is applied. The corners of this band are rounded with $\frac{1}{4}$ in. radius. The various sizes of tires are to be submitted respectively to pressures in accordance with the following table. For the tire to pass successfully the hard rubber must not break loose from the base.

9. *Life:* A minimum life of 7000 miles per tire must be assured.

Size of Tire	In. Diam. of Press Ring	Lb. per Lineal Inch	Pressure in Tons on Tire, Max.	Size of Tire	In. Diam. of Press Ring	Lb. per Lineal Inch	Pressure in Tons on Tire, Max.
32x3	29	175	8	32x3½	29	220	10
34x3	31	175	9	34x3½	31	220	11
36x3	33	175	9	36x3½	33	220	11
32x4	29	325	14	32x5	29	400	18
34x4	31	325	16	34x5	31	400	19
36x4	33	325	17	36x5	33	400	21
38x4	35	325	18	38x5	35	400	23
40x4	37	325	19	40x5	37	400	23
42x4	39	325	20	42x5	39	400	24
32x6	29	475	21	36x7	33	550	28
34x6	31	475	23	38x7	35	550	30
36x6	33	475	24	40x7	37	550	31
38x6	35	475	26	42x7	39	550	33
40x6	37	475	27	36x8	33	550	29
42x6	39	475	29	40x8	37	550	33
1110x100 mm.	47	325	24	1000x125 mm.	43	400	27

The above gives an idea of the service which may reasonably be expected of a solid tire. If it is well built and of good material properly compounded, it will give

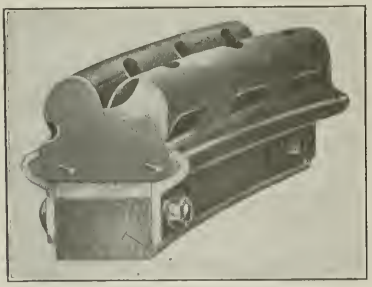

FIG. 10. CUSHION TIRE FOR ELECTRICS

good service, with the final provision that it receive fair treatment. It must not be overloaded, driven at speed higher than allowed, or run for long periods of time without being given a chance to cool off. When heavy loads are to be carried it is preferable in point of service to substitute duals for a single large tire. Thus where a 14-in. size is necessary two 7-in. tires will be found more satisfactory.

The compounding of solid tires is not easy. There are so many factors that must be handled to a nicety that it is hard to get the proper balance between them. The chief difficulties may be stated as follows:

(*a*) *Union:* The hard rubber must make good union with both tread and band.

(*b*) *Body and Hardness of Tread:* The stock used here must be heavily compounded so as to stand up well under the load. If it is too soft it will cut and large chunks will be torn out.

(*c*) *Easy Working:* The stock must be of a nature which will allow it to tube readily.

Cushion Tires

The cushion tire is a hybrid. It is both a solid and a pneumatic—and neither. It is merely a solid tire with a hole in it. The hole may be either inside or outside. There have been advanced more than a thousand designs based on this principle, but none of them ever become really popular. The reason is simple. If the tire is to function as a pneumatic, the walls of the air space are too heavy to stand the flexing without considerable heating up and subsequent decomposition.

The proposition is in some ways parallel to the tire filler (pneumatic). This phœnix is revived year after year, and sad to state the unsophisticated always fall for it. They forget that rubber is the most incompressible substance known. It can be easily deformed but never compressed. In designing a tire to carry a load one must first decide whether he will secure the desired cushioning solely by rubber itself or if air is more suitable. If after careful consideration of the conditions he decides on the first solution he will make a solid tire. If air is to be depended upon he will design the walls of his container in such a way that they will stand flexing.

The trouble with a cushion tire is that it will not stand any large amount of bending without suffering serious injury. In practically every instance where a cushion tire appears to give satisfaction it will be found that it has been very lightly loaded and the degree of flexing has not been high. One can safely say that there is no field for the cushion tire. Practically every application can be as well or better served by either a pneumatic or a solid. This does not mean that it may be substituted by both a pneumatic and a solid, but that one of the two will prove more satisfactory.

This statement must be qualified, however, since there is one very good place for the cushion tire with outside air spaces, and that is on small electrics. These cars are light, travel at slow speed over good streets, and are usually driven by women. Their advantage is twofold: first, the uneven surface gives it non-skid properties, and, second, there are no punctures. This fact means much to an elderly lady. To her the tire is reliable, for, like the famous flivver, "it gets you there and gets you back." She drives slowly, and the jolts are greatly decreased.

The manufacture of such tires is simple. The tube machine runs them out in sticks of the proper length and approximately the proper shape. The tires are built by hand. The fabric base is put on, and the tire spliced

in the usual way with the jammer. The knobs, depressions and special designs are put on in the molds during curing.

Stocks used for cushion tires are necessarily of a higher quality than for solids. They must have a higher tensile strength and higher stretch. The best of them will show a tensile strength of close to 3000 lb. per sq.in. and a stretch of 400 to 500 per cent.

Conclusion

The above is in general the history of solid tire development. During the war motor trucks were a deciding factor. They proved to be the red corpuscles not only of the battlefield but of industry. Every territory formerly dominated by the railroads has been seriously invaded. Surely the lessons learned in war will not be forgotten in peace. The next ten years will see the greatest truck expansion the world has ever known. With it will come extensive road building. The solid truck tire will dominate the field for a long time at least. Sales on pneumatic truck tires may be developed sufficiently to displace solids almost entirely, but the writer feels that an entirely new scheme of design will have to be worked out. Merely increasing the dimensions of the automobile tire will not prove successful.

The writer has attempted to set before the reader some of the salient features of solid tire design and manufacture, without going too much into detail. While the conclusions advanced are the result of his own observations and experience, he realizes very well that all solid tire men will not agree with him, and therefore offers them simply as his own opinions, which he believes in the main to be correct.

Our country undoubtedly faces a complete revision in transportation. Good roads will be constructed to every corner of the land. The bulk of our commerce will in the future be carried on trucks. Whether they will be equipped with solid or pneumatic tires is yet to be seen. It appears now that express trucks will ride pneumatics but that regular freight service will depend on solids. Good roads and plenty of gasoline or an efficient substitute will be found among the deciding factors.

Cleaning Furnace Gases Without the Use of Water

By J. C. Barrett
Superintendent of Blast Furnaces, Carnegie Steel Co., Youngstown District

Realizing the inefficiency of the various methods of cleaning and burning blast-furnace gases, F. E. Kling, chief mechanical engineer, and Luther B. Weidlein, experimental engineer of the Ohio works, Carnegie Steel Co., Youngstown, Ohio, five years ago started experiments to overcome the difficulties. In the course of their experiments, they developed a very efficient gas burner for boilers, which is truly an aspirating burner and fulfills the rigid specifications required for burning blast-furnace gas efficiently. After completing this phase of the problem, steps were taken to make a comparison of results obtained from burning gas which had been cleaned or partly cleaned by various means, and dirty gas taken directly from the dust catcher.

The first experiment was carried out with gas that had passed through an impinging type of wet washer. This type of washer was found to be very inefficient, as it reduced the temperature about 50 per cent, was not more than 50 per cent efficient in removing the dust, and the gas picked up about 15 per cent additional moisture. The item of reduced temperature alone was sufficient to condemn this method, disregarding the high dust content of the gas. Aside from the loss of the sensible heat due to reduced temperature and increased moisture content of the gas, the quantity of dust which the gas carried through the washer was just as detrimental to obtaining boiler and hot-blast-stove efficiency is if the gas had not been cleaned at all.

The next experiment was made with gas that had passed through the cleaning plant for gas engines, which includes a spray tower, baffle tower, and Theisen washer. Even if the gas were desirable for boilers or hot-blast stoves, this method of cleaning would be prohibitive from the standpoint of cost. A disadvantage of this method, disregarding the cost, is the fact that the sensible heat of the gas is reduced to such a point that the usual size combustion chamber is not long enough to obtain complete combustion. The gases, therefore, enter the boiler proper partly unburnt, coming in contact with the heating surface of the boiler, which is the temperature of the steam, causing the gases to give up the heat of combustion, thereby reducing the temperature of the unburnt gases below the ignition temperature, with the consequent incomplete combustion of the gases, resulting in a loss that might otherwise be prevented.

The moisture content of the gas was reduced to about 30 per cent of the original with this method of washing. To accomplish this, however, it was necessary to reduce the temperature of the gas to the temperature of the water used for cleaning. If the temperature and the moisture content of the gas entering the boiler were the same as in the waste gases leaving the boiler, it would not be possible to sustain the loss of a single B.t.u. With any normal operating condition of the blast furnace, there is a decided advantage in favor of retaining the temperature of the gas as coming from the furnace, even in view of the fact that the gas contains the additional amount of moisture. An experiment was then made with hot gas taken directly from the dust catcher, and much better results and efficiencies were obtained than with either of the former experiments, although large quantities of dust had to be contended with, and the dust had to be blown off the boiler tubes frequently.

In view of the results obtained from the above experiments, and the advantages so prominent in favor of hot gas, various means were employed to develop a cleaning method in which the dust could be removed from the gas without reducing the temperature. After careful study and experiment, a very novel means of removing the dust from the gas was developed, and an experimental cleaner was built, designed to handle 6000 cu.ft. gas per minute at 62 deg. F. This plant was in operation, off and on, for about six months, being taken off and changed as various improvements were developed. Results were obtained that were truly remarkable in view of the difficult problem of removing the very fine or impalpable powder from the gases—results that equal and surpass cleaning efficiencies of the best types of wet washers.

The gas passing through this experimental cleaner

was consumed under a 400-hp. Stirling boiler, and after a month's operation, without blowing the tubes, there was less than 50 deg. F. increase in temperature of waste gases on account of the dust accumulation. What little dust came through the cleaner was of such nature that a large portion of it was carried through the boiler and out with the waste gases. However, the portion deposited on the tubes was easily removed by blowing it with a hand steam lance. The dust carried by gas which has been wet-washed bakes onto the tubes and is hard to remove. During a slip of the furnace, the dry cleaned gas would burn as usual, while the flame would extinguish in an adjoining boiler, using wet washed gas, due to excessive dust. The boiler was completely equipped with recording instruments, and it was shown that it would not be necessary to blow the tube oftener than once in two to three weeks to maintain almost uniform boiler efficiency.

This experimental cleaner was inspected by various individuals and committees, and was pronounced a remarkable development, and one which would revolutionize cleaning methods for blast-furnace gases. Due to the very satisfactory results obtained from the above experiment, the United States Steel Corporation authorized the installation of a cleaner large enough to clean all of the gas from one blast furnace. This cleaner was installed at No. 1 blast furnace of the Ohio works, Carnegie Steel Co., Youngstown, Ohio, and was built and ready for operation without interfering with the operation of the blast furnace, the latter being banked only long enough to make a connection to the existing dust catcher. This furnace has a capacity of 550 tons of iron per day, and produces 80,000,000 cu.ft. of gas which passes through the cleaner daily.

The cleaner proper was constructed of reinforced slag concrete due to the scarcity of steel plates during the war. The accompanying photograph shows the cleaner in course of construction. The idea of using concrete for this purpose is quite novel in itself. This structure was built to withstand an explosion pressure of 15 lb. per sq.in., and it is well equipped with explosion valves of special design, which are set to open at 1 lb. pressure per sq.in. The walls, being 15 in. thick, act as a very good insulator to retain the temperature of the gas. The concrete has shown no deterioration, and has withstood all conditions to which it will be subjected, and no trouble is anticipated.

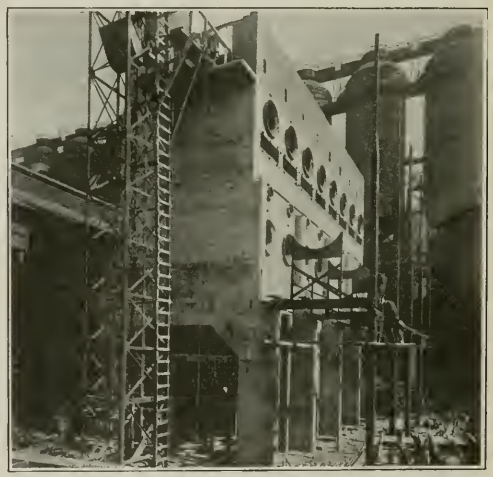
With inquiries favoring steel plate in preference to concrete, the inventors have designed a very adaptable construction which should appeal to the most skeptical. A course of Sil-o-cel insulating brick was used in addition to the regular lining of firebrick in the gas piping, as the idea of retaining the sensible heat in the gases was foremost in the minds of the inventors.

The operation of the cleaner is entirely automatic and does not require constant attendance. One of the men from the regular force maintained in blast-furnace operation inspects and lubricates the machinery once or twice a day.

That the project was well engineered is shown by the fact that the cleaner, when put in operation about two months ago, without any preliminary trials, worked satisfactorily, which is remarkable when considered that it is the first large installation of its kind. This cleaner has been in continuous operation since that time, which demonstrates that it is thoroughly reliable. The power required to operate this cleaner 25 per cent of the time is 4.25 hp., and 75 per cent. of the time 2 hp., making an average power requirement of 2.58 hp. as compared with 80 hp. to 100 hp. for wet washer. The dust is accumulated in hoppers of sufficient capacity to hold two or three days' accumulation. It is then dumped into standard hopper cars, the operation requiring only about one-half hour to remove the dust from the cleaner.

Since this cleaner has been in operation, an additional 25 per cent of dust in the gas leaving the dust catcher has been reclaimed. Heretofore, this was carried away in the water that was used for washing the gas, although it was supposed that very complete settling of the dust was being obtained in large settling basins. The average amount of dust deposited in this cleaner since starting operations is 63,500 lb. per 24 hr., although the gas has previously passed through a dust catcher 30 ft. in diameter. This represents 48.6 per cent of the total dust leaving the furnace by way of the downcomers. The cleaner is maintaining a cleaning efficiency of 90 to 97 per cent, the dust content in clean gas being 0.10 to 0.30 grains per cu.ft. at 62 deg. F.

The range of temperatures of the gases which have passed through this cleaner is 150 to 800 deg. F., and the average loss in temperature due to radiation is 25 deg. F. to 35 deg. F., with atmospheric temperature ranging down to 10 deg. F. There have been instances where the temperature of the outgoing gas has been



DRY GAS CLEANER

150 deg. F. higher than the incoming gas. This is due to a condition where the incoming gas was very low in temperature, the massive concrete walls having stored up the heat from gas of high temperature which previously passed through the cleaner, and giving it up to the gases of low temperature, the structure acting as a heat equalizer.

The resistance to flow or back pressure on the furnace is only 2 to 3 in. water gage. This includes all piping to and from the cleaner, and the cleaner itself. This is considerably lower than the resistance through any type of wet washer. The cleaner is connected to a blast furnace that has been in operation for four years on the present lining, and it has been subjected

to all of the conditions which are characteristic of an old furnace. The cost of an installation for cleaning gas by this method compares very favorably with the cost of a complete wet washing outfit; and considerably less ground space is required, due to the absence of settling basins.

The beneficial results from this method of cleaning are so pronounced that great interest has been shown in the form of inquiries and investigations, and they demonstrate the opportunities which are paramount in the field of dry cleaning furnace gases. During the comparatively short time that this method has been demonstrated, several additional installations have been contemplated at various places, including another cleaner to be built at the Ohio works. Adopting the method of dry-cleaning gas permits other changes in practice that appear on the whole to be very advantageous. By having hot gases enter the hot-blast stoves, it is possible to obtain higher flame temperature in the stoves, which will result in a saving of coke, since a higher hot-blast temperature will be available. It will be possible to operate the furnace with fewer stoves by equipping the stoves with smaller checkers, thereby obtaining better operating efficiency. An installation for cleaning all of the gas from a furnace would cost about the same as a hot-blast stove.

A summary of the advantages to be obtained by the dry cleaning over wet washing of furnace gases is as follows:

Sensible heat of the gas is retained.
When burned under boilers, the gas generates more steam.
When burned in hot-blast stoves, produces higher blast temperature.
No water is required for cleaning the gas.
No settling basins are required.
Less ground space required, due to absence of settling basins.
No pollution of streams.
Less labor cost in handling the dust.
Less than one-tenth the power required to operate.
Less back pressure on the furnace.
Cleaning efficiency as good as the best types of wet washers.
No sludge dripping from gas mains and burners.

Book Reviews

MILL AND CYANIDE HANDBOOK. By *A. W. Allen.* 128 pages, with diagrams and charts; price $2.00. Philadelphia: J. B. Lippincott Co.

This addition to the many handbooks recently issued has been planned to cover a narrow field. Its subject matter is devoted to the winning of the precious metals by amalgamation and cyanidation. The book is of English origin. It typifies English methods and draws its material largely from English sources. For instance, its tables consist in considerable part of data from South African practice, and thus may be explained the complete absence of concentration and of flotation data. From the American viewpoint, this circumstance is at once a strength and a weakness of the book—the one since it brings the reader useful data not easily available, the other by its inclusion of the conversion tables for English moneys and measures.

To readers of the technical press, who have known the author as a writer of exceptionally precise expression and of thorough acquaintance with his subject, the first impression of the book is distinctly disappointing. Closer examination discloses much useful matter, but this impression is never wholly dissipated. Criticism is somewhat disarmed by the author's statement that the data were collected prior to 1914. The book seems to lack systematic arrangement—a fault perhaps more of the publisher than of the author—and the matter is of unequal merit. The presentation of all data in tabular or graphic form is novel and is doubtless the logical method for a book of this class. The style offers some difficulties, as for instance in the description of assay methods, and it tempts to the expansion into a table of what could as well be compressed into a single line. Thus the weight of sheet-lead is readily derived from the weight of a unit volume of this material. Again, the matter in Section 5 could have been expressed more simply without loss.

The launder data—page 62—are insufficient. The general formulæ, as of Blue and Caldecott, are not given, and the valuable data of Washoe and Cananea, published a few years ago in the *Engineering & Mining Journal*, are missing. We find nothing of cyanide antidotes, or of volumes of conical classifiers, and not enough of weights of materials or of hydraulic equivalents.

The author's excellent formulæ for the calculation of extraction and of recovery are given. It is to be regretted that he deemed the scope of the book insufficient to include Hoover's formulæ for concentration. The tabular matter is followed by a series of typical flow-sheets, useful for reference, and these by a group of report-forms of rather doubtful value. An excellent glossary closes the volume.

Personal

Mr. Robert J. Anderson has resigned as research metallurgist with the Bureau of Aircraft Production, Detroit, and will join the staff of the Bureau of Mines. He will make special investigation in the metallurgy of aluminium and other non-ferrous metals, at the experiment station at Pittsburgh.

Major Charles V. Bacon, who was engaged during the war on investigation relating to liquid fire and war gas, has been made chief of the Research Section of the Engineering and Standardization branch P. S. & T. division of the General Staff.

Capt. C. L. Colburn has returned from service with the Corps of Engineers, and has resumed his former work as assistant metal mining engineer for the Bureau of Mines, stationed in Washington.

Dr. Henry M. Howe is to sail for Europe early in April for a stay of about three months.

Mr. Walter Renton Ingalls, editor of *Engineering & Mining Journal* for nearly 14 years, has resigned to reenter professional practice as a consulting engineer, with offices at 115 Broadway, New York City.

Dr. A. D. Little recently addressed the Industrial Association in Cleveland on the industrial utilization of chemical research.

Mr. Dorsey A. Lyon, supervisor of stations for the Bureau of Mines, is on an extended Western trip of inspection.

Capt. A. C. Nell, Construction Division, U. S. A., has been released from active duty in the Army, and has been appointed Chicago district manager for the Lea-Courtenay Co. and the Schutte & Koerting Co.

Mr. H. C. Parmelee, editor of Chemical & Metallurgical Engineering, has been appointed acting editor of the *Engineering & Mining Journal*, vice Mr. Walter Renton Ingalls, resigned.

Mr. F. R. Still, vice-president and secretary of the American Blower Co., has left on an extended trip for the Far East, where he will investigate trade conditions in connection with export work. His itinerary includes Japan, China, Australia and most of the European countries.

Dr. T. B. Wagner, chief chemist of the Corn Products Refining Co., New York City, has resigned to take a similar position with the United States Food Products Corp., 40 Exchange Pl., New York City, which has lately succeeded to the business of what was formerly known as the Distillers Securities Corporation.

Current Market Reports

The Non-Ferrous Metal Market

Monday, March 24. — Prices on the non-ferrous metal market are inviting to buyers and large transactions are impending.

Aluminium:—Conditions are unusually quiet, as aluminium has not declined. Ingots 98-99 per cent, 31c. lb. Sheets, 18 gage and heavier, 42c. Powder, 0.70-1.40 lb.

Antimony: — Wholesale lots are offered from 7c. to 7⅛c. and jobbing at 7¼c. There is no active buying.

Copper: — No sustained buying has taken place, with prices as low as 15c. lb.

Copper sheets, hot-rolled	lb.	$0.22½—
Copper sheets, cold rolled	lb.	.23½—
Copper bottoms	lb.	.30½—
Copper rods	lb.	.19½—
Copper wire	lb.	.18 —
High brass wire and sheets	lb.	.18½—
High brass rods	lb.	.17½—
Low brass wire and sheets	lb.	.18½—
Low brass rods	lb.	.21½—
Brazed brass tubing	lb.	.29½—
Brazed bronze tubing	lb.	.33½—
Seamless copper tubing	lb.	.28 —
Seamless bronze tubing	lb.	.29½—
Seamless brass tubing	lb.	.30 —
Bronze (gold) powder	lb.	1 00 —

Lead: — No change has occurred with lead. East St. Louis quotes 4.90-5.00c. per lb. and New York 5¼c. Sheet lead, 8-8¾c. lb.

Tin: — The fixed price of 72½c. will remain until the 10,000-ton allotment is liquidated, which will be from sixty to ninety days yet.

Zinc: — Spelter remains unchanged, with East St. Louis prices showing no future decline from $123.50 per ton. Zinc dust, 14c. Sheet zinc, 11c. lb.

OTHER METALS

Bismuth	lb.	$3.20 — $3.65
Cadmium	lb.	1.40 — ....
Cobalt	lb.	2.50 — 3.50
Magnesium	lb.	1.75 — 2.10
Mercury	75 lb.	68.00 — ....
Nickel	lb.	.40 — .45
Tungsten	lb.	Nominal
Iridium	oz.	175.00 — .....
Palladium	oz.	115.00 —
Platinum	oz.	95 00 —100.00
Silver	oz.	1 01⅛— .....

The Iron and Steel Market

A wide variety of opinion has been expressed on the price reductions made in pig iron, unfinished steel and finished steel products as a result of the activities of the Industrial Board of the Department of Commerce. This board, the conception and creation of Secretary of Commerce Redfield, undertook to deflate commodity prices, particularly those involved in construction work, for the purpose of stimulating business activity. As noted in last report, at a meeting of iron and steel purchasers March 6 there was a unanimous vote to co-operate with the board. A meeting between the industry's committee and the board was arranged for March 12, but was postponed one week. When the two bodies met, Wednesday morning, March 19, the producers' committee did not have a schedule of prices and asked for time to deliberate further, stating it would meet the board in the afternoon. Later it asked that the meeting be deferred until the following morning. It was not ready then, and it was not until 11.45 Thursday night that a partial schedule was completed. The producers put the reduced prices in effect as of the following morning, the precise time being important inasmuch as invoice prices of shipments of much finished steel hinged upon the price, the producers being disposed, according to trade custom, to give customers the advantage of any market declines.

Since the new prices were announced there has been some criticism of them by producers, though not a great deal, the disposition being to make the best of the situation. The adjustment may better be judged by opinions freely expressed in the trade before the new prices were formulated. There was then expressed very widely the opinion that steel prices should not be cut at all, or should be cut deeply. No small reduction, it was urged, at all comparable to the reduction of last December would do any good. A small reduction would cause the steel mills to receive less money for deliveries against orders already on books, while it would not stimulate or increase consumption. These utterances have proved unfortunate, since that is precisely the kind of a reduction that has been made. Members of the committee have been indisposed to divulge the nature of the discussions that kept them so long in reaching a conclusion, but one may perhaps guess that what was done represented a compromise between counsel for no reduction and counsel for a large reduction. The matter had been so widely advertised, and buyers were so generally holding back orders in anticipation of reductions that something had to be done.

Extent of Reductions

The reductions made were as follows: Pig iron, $4.25 per gross ton; unfinished steel, $5 per gross ton; wire products and grooved steel skelp, $5 per net ton; all other rolled steel products, $7 per net ton. The trade adopts the practice of applying the $4.25 reduction to the last Government prices, allowing for the $3 reduction previously made. War Industries Board extras, differentials, basings, etc., are to obtain. Obviously this will not work out for any length of time, since the furnacemen are not used to such an artificial price structure, nor indeed can it be fully maintained. The price of No. 2 foundry iron would be the same, $26.75, f.o.b. valley furnaces, Ironton furnaces, Chicago furnaces and Birmingham furnaces, and Birmingham could not reach a sufficient market, on account of freights. Immediately one small divergence occurred. More or less by chance, apparently, malleable iron had been set, under Government control, at 50c. above foundry iron, while foundry iron was $1 above basic. Normally much of the malleable iron produced is simply off basic. Immediately upon the announcement of the new prices a prominent valley furnace interest offered to sell malleable at 50c. above basic, which would be 50c. below foundry instead of 50c. above.

The new prices on unfinished steel are: Billets, $38.50; 2-inch billets, $42; sheet bars, $42; slabs, $41; rods, $52. All these products had been reduced $4 in December, except rods, which were not reduced. The new finished steel prices, in cents per pound, are: Bars, 2.35c.; shapes, 2.45c.; plates, 2.65c.; grooved steel skelp, 2.45c.; universal mill skelp, 2.55c.; sheared skelp, 2.65c.; merchant steel pipe, 57½ per cent basing discount; plain wire, 3c.; wire nails, $3.25 per keg; black sheets, 28 gage, 4.35c.; blue annealed sheets, 10 gage, 3.65c.; galvanized sheets, 28 gage, 5.70c.; tin plate, $7 per base box, 100-pound.

Price Comparisons

No. 2 foundry pig iron was $33 under Government control, advancing to $34 by the settlement late in September, 1918, becoming $30 about Jan. 1, 1919, and now declining to $26.75, basic iron being $1 less, while bessemer is $27.95. Foundry iron at valley furnaces 1904 to 1913 inclusive averaged $15.68. The ten-year pre-war average in billets was $24.82, the Government price being $47.50, while the present price is $38.50. A weighted average of bars, shapes, plates, pipe, wire products, sheets and tin plates shows the following, per net ton: Ten-year pre-war average, $36; Government limit, $76; after December reductions, $72; after March reductions, $65. Thus prices remain above the pre-war average as follows: Pig iron, 71 per cent; billets, 55 per cent; finished steel, 81 per cent.

Market Prospects

Both official statements on the price adjustment, that of Judge Gary, chairman of the producers' committee, and that of the Industrial Board, state in substance that the new prices are to be minimum for the remainder of the year. If, however, the price reduction does not greatly stimulate consumption the way will be open for a further consideration of the subject, say in June or September. The experience of the first few weeks after these reductions will not prove sufficient for a long range prediction. Buyers were making purchases only from hand to mouth, but even under that policy they were able to hold back orders for a short time, when they saw the prospect of reductions being

made. As the new prices would in any event hold for a time, buyers who are supplying ordinary everyday requirements are naturally buying freely and the market is moderately active. The rate of steel production, which was 85 per cent in January and only a shade less in February, had declined in March, but will probably hold at about 75 per cent for a while.

The investment buyer, on the other hand, cannot be heard from at once and it will require some time to observe how he takes the reduction. The investor, furthermore, considers other materials than steel, including lumber, brick, cement, etc. These and other commodities are still to be taken in hand by the Industrial Board and the investor will be disposed to wait and see what luck the board has with these commodities. Thus the real test of the new steel prices can hardly occur within the next month or two.

The steel trade has accepted the new arrangement as distinctly a price maintenance one. with support by the Industrial Board and absolution of the Department of Justice, with which department there was close contact during the negotiations. There is, however, an important divergence between the situation now and that which obtained during the price maintenance of 1908. At that time distribution of orders was arranged whereby all producers operated at substantially the same rate and thus there were no jealousies. In the past few weeks there has been a wide divergence in the rates at which the various producers have operated.

The Chemical Market

Coal-Tar Products.—The situation in general has undergone no material change in the interim. While at this writing a firmer tendency prevails in the crudes, with buyers showing more interest than formerly and weak sellers fairly well cleaned out, the intermediates have not followed suit and if anything they are weaker than formerly, although quoted prices are about the same. The reason for the weakness in price of the intermediates is attributed in the main to the fact that more concerns are producing with unusually large quantities of surplus material on the market. Buyers, on the other hand, have not increased, and in fact have decreased, and those who were accustomed to laying in large stocks to bridge over eventualities find it unnecessary to do so while conditions continue as they are.

Phenol:—This market has firmed up considerably due to the elimination of several second hands who were holding large quantities for foreign governments. The inquiry has improved and though there are not as many large sales being closed as formerly, the volume of comparatively small sales is quite satisfactory in the aggregate.

Benzol:—It is still possible to shade producers' prices, due to the fact that large quantities are held in second hands, but prices are in the main well maintained in both quarters. A fair volume of business is passing, although the former tendency on the part of buyers to stock up for long periods has abated somewhat, and in most quarters they are buying only sufficient to cover for present requirements.

Toluol:—Buyers are displaying more interest than they have for some time past. Material is for the most part held by producers, with only limited quantities available in second hands, so that there is but little business passing through the latter hands and prices are on a firmer basis.

Naphthaline:—There is not a great deal of business passing in this item. Consumers appear to be indisposed to stock up for more than immediate requirements and the volume of business closed is not as great as sellers would like to see. Prices are, as a result, considerably easier.

Aniline Oil:—Large quantities of this material are available at present with only a moderate demand and some marked concessions in price have resulted. While producers are not generally inclined to reduce quoted prices, firm bids at less than quoted prices have been accepted.

Aniline Salt:—The increased output has resulted in a weaker position and in the desire to move material low prices have been accepted in several instances.

Paranitraniline:—A fairly active business is passing, but there are several concerns producing, with surplus stocks on the market and prices lower.

Salicylic Acid:—With little or no demand prevailing and large quantities on the market, prices are considerably lower.

Benzoate of Soda:—Both the soda and acid have felt the effect of curtailment of export demand and lower prices are in order as a result.

Salol:—The demand is not pressing and though there are sales of moderate quantities passing, the position is anything but firm.

Dimethylaniline:—Business is passing in fair volume but is considerably less than dealers can take care of, and despite attractive prices buyers are seemingly not greatly interested.

Anthracene:—A fairly active demand prevails, and with only a few producers in the field prices are fairly well maintained.

Resorcin:—The production is confined to a few quarters, with an active demand and prices unchanged.

Heavy Chemicals.—Despite the fact that inducements in the way of what are considered attractive prices, buyers are seemingly disinclined to contract over long periods, or to buy more than sufficient material to cover current requirements. As a result, there is considerable gunning for business on the part of large producers and prices have, in a great many instances, been shaded in an endeavor to move surplus stocks. Such large business as is passing is generally confined to the filling of export orders, but even this avenue of consumption is considerably clogged up due to the present harbor strike and the resultant difficulty in moving material so that it will reach the vessels by sailing time. There is also considerable difficulty encountered in getting buyers on old contracts to accept material due to the drop in price.

Caustic Soda:—Compared with the few weeks preceding, the past week has seen some improvement in the volume of trading. Prices, however, have weakened, if anything, due to liberal offerings and the keen competition prevailing among the many holders. Sales of material f.a.s. have been made in exceptional cases as low as $2.60, although $2.70 to $2.75 is more representative of the prices prevailing in most instances. Material ex-warehouse sold at $2.55 to $2.60 on the average. A sale of a goodly quantity of resale material threatened, for a time, to have a disturbing effect, but it was subsequently withdrawn from the market.

Soda Ash:—Although some very liberal inducements are made to buyers, they do not appear to be inclined to buy heavily, and such business as is passing is for very small quantities. The general outlook based upon conditions prevailing the past few weeks appears to have a depressing effect on the market. Sales were made ex-warehouse in bags at $1.55 to $1.60.

Bleaching Powder:—The arrival of large quantities on the market, with such buying interest as there is confined to export orders and these not heavy, has caused an easier price position, although quotations in general are unchanged. Export drums are available at $2.25, with domestic drums at $1.60 to $1.65.

Copper Sulphate:—Comparatively large sales are being closed and it is possible to shade prices in a great many instances. From $7.15 to $7.25 is quoted for outside brands, with standard brands somewhat higher.

Formaldehyde:—There is an active business passing in this item, but stocks are ample and sales have been closed at 22c. in the past week.

Sodium Sulphide:—Buying pressure is not heavy and sales are passing here and there at a shade under former prices.

Nitrate of Soda:—There are only small lots of 25 to 50 tons in all that are available on the resale market, at $4.05 to $4.07½. The Government-fixed price of $4.07½ continues to be maintained.

Glycerine:—The bulk of sales passing is for small quantities, and prices are somewhat lower.

Calcium Carbide:—There is only a moderate volume of business passing and from time to time concessions in price are made, with 6¼c. to 6½c. quoted.

Arsenic:—Such sales as are passing are for comparatively small quantities. The white material, which is in fair demand, is quoted at 9c. to 9¼c. The red is quite neglected, with 26c. to 31c. quoted.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET MARCH 24, 1919

Acetic anhydride	lb.	.90	—	1.00
Acetone	lb.	.15½	—	.16
Acid, acetic, 28 per cent	cwt.	3.25	—	3.40
Acetic, 56 per cent	cwt.	6.50	—	6.75
Acetic, glacial, 99½ per cent, carboys	cwt.	14.00	—	14.50
Boric, crystals	lb.	.13½	—	.15
Citric, crystals	lb.	1.25	—	1.25½
Hydrochloric, (22%)	cwt.	2.50	—	3.00
Hydrofluoric, 30 per cent, in barrels	lb.	.08	—	.08½
Lactic, 44 per cent	lb.	.15	—	.16
Lactic, 22 per cent	lb.	.06	—	.07
Molybdic, C. P	lb.	6.90	—	7.40
Nitric, 36 deg	lb.	6.60	—	6.85
Nitric, 42 deg	lb.	.08½	—	.10
Oxalic, crystals	lb.	.32	—	.34
Phosphoric, 47-50 per cent paste	lb.	.07½	—	.10
Phosphoric, ref. 50 per cent	lb.	.26	—	.30
Picric	lb.	.50	—	.75
Pyrogallic, resublimed	lb.	2.70	—	3.20
Sulphuric, 60 deg. works	ton	12.00	—	14.00
Sulphuric, 66 deg. works, tank cars	ton	17.00	—	25.00
Sulphuric, oleum (fumitg), tank cars	ton	25.00	—	26.00
Tannic, U. S. P., bulk	lb.	1.40	—	1.50
Tartaric, crystals	lb.	.86½	—	.87
Tungstic, per lb. of W	lb.	1.60	—	1.75
Alcohol, sugar cane, 188 proof	gal.	4.91	—	.....
Alcohol, wood, 95 per cent	gal.	1.28	—	1.30
Alcohol, denatured, 180 proof	gal.	.40	—	.42
Alum, ammonia lump	lb.	.04½	—	.05½
Alum, chrome ammonium	lb.	.17½	—	.18
Alum, chrome potassium	lb.	.20	—	.22
Alum, chrome sodium	lb.	.12½	—	.13
Alum, potash lump	lb.	.10	—	.12
Aluminium sulphate, technical	lb.	.02	—	.02½
Aluminium sulphate, iron free	lb.	.03	—	.03½
Ammonia aqua, 26 deg., carboys	lb.	.07	—	.08½
Ammonia, anhydrous	lb.	.30	—	.35
Ammonium carbonate	lb.	.13	—	.14
Ammonium nitrate	lb.	.16	—	.17
Ammonium sulphate, domestic	lb.	.05½	—	.05½
Amyl acetate	gal.	3.50	—	3.75
Arsenic, white	lb.	.09½	—	.10
Arsenic, red	lb.	.35	—	.40
Barium carbonate, 99 per cent	ton	80.00	—	90.00
Barium carbonate, 97-98 per cent	ton	65.00	—	67.00
Barium chloride	ton	70.00	—	80.00
Barium sulphate (blanc fixe, dry)	lb.	.03½	—	.04
Barium nitrate	lb.	.10	—	.11
Barium peroxide, basis 70 per cent	lb.	.30	—	.32
Bleaching powder, 35 per cent chlorine	lb.	.01½	—	.02½
Borax, crystals, sacks	lb.	.07½	—	.08½
Brimstone, crude	ton	28.00	—	35.00
Bromine, technical	lb.	.55	—	.60
Calcium acetate, crude	lb.	.04	—	.05
Calcium carbide	lb.	.06½	—	.06½
Calcium chloride, 7-75 per cent, fused, lump	ton	18.00	—	22.00
Calcium peroxide	lb.	1.50	—	1.70
Calcium phosphate	lb.	.22	—	.23
Calcium sulphate, 98-99 per cent	lb.	.09	—	.09½
Carbon bisulphide	lb.	.07	—	.08
Carbon tetrachloride, drums	lb.	.14	—	.15
Carbonyl chloride (phosgene)	lb.	.75	—	1.00
Caustic potash, 88-92 per cent	lb.	.50	—	.60
Caustic soda, 76 per cent	100 lb.	2.60	—	2.75
Chlorine, liquid	lb.	.10	—	.12
Cobalt oxide	lb.	1.60	—	1.65
Copperas	lb.	.01½	—	.02½
Copper carbonate	lb.	.31	—	.32
Copper cyanide	lb.	.65	—	.70
Copper sulphate, 99 per cent, large crystals	lb.	7.15	—	7.50
Cream of tartar, crystals	lb.	.55	—	.58
Epsom salt, bags, U. S. P	100 lb.	2.75	—	.....
Formaldehyde, 40 per cent	lb.	.22	—	.22½
Glauber's salt	lb.	.02	—	.02½
Glycerine, bulk, C.P	lb.	.17½	—	.18
Iodine, resublimed	lb.	4.25	—	4.30
Iron oxide	lb.	.06	—	.08
Lead acetate, white crystal	lb.	.12½	—	.14
Lead arsenate (paste)	lb.	.15	—	.18
Lead nitrate, C. P	lb.	.85	—	.86
Litharge, American	lb.	.10	—	.11
Lithium carbonate	lb.	1.50	—	.....
Magnesium carbonate, technical	lb.	.16	—	.17
Nickel salt, single	lb.	.14	—	.15
Nickel salt, double	lb.	.12	—	.13
Phosgene (see carbonyl chloride)	lb.	.75	—	1.00
Phosphorus, red	lb.	.75	—	.80
Phosphorus, yellow	lb.	.35	—	.40
Potassium bichromate	lb.	.37	—	.38
Potassium bromide, granular	lb.	1.25	—	1.26
Potassium carbonate, calcined, 85-90 per cent	lb.	.17	—	.18
Potassium chlorate, crystals	lb.	.39	—	.41
Potassium cyanide, 98-99 per cent	lb.	2.50	—	2.75
Potassium iodide	lb.	3.75	—	3.80
Potassium muriate, 80-85 p. c. basis of 80 p. c.	ton	200.00	—	250.00
Potassium nitrate	lb.	.26	—	.30
Potassium permanganate, U. S. P	lb.	.80	—	.82
Potassium prussiate, red	lb.	1.50	—	1.60
Potassium prussiate, yellow	lb.	.55	—	.58
Potassium sulphate, 90-95 p. c. basis 90 p. c.	ton	Nominal		
Rochelle salts	lb.	.46½	—	.48
Salammoniac, gray gran	lb.	.14	—	.16
Salammoniac, white gran	lb.	.12½	—	.13
Sal soda	100 lb.	1.60	—	2.00
Salt cake	ton	20.00	—	22.00
Silver cyanide, based on market price of silver	oz.	.....		.....
Silver nitrate	oz.	.62½	—	.63½
Soda ash, 58 per cent, light, flat (bags)	100 lb.	1.55	—	1.60
Soda ash, 58 per cent, dense, flat	100 lb.	2.45	—	3.00
Sodium acetate	lb.	.07½	—	.08
Sodium bicarbonate, domestic	lb.	.02½	—	.03
Sodium bicarbonate, English	lb.	.....		.....
Sodium bichromate	lb.	.12	—	.14
Sodium bisulphite, powd	lb.	.05	—	.07
Sodium chlorate	lb.	.16	—	.18
Sodium cyanide	lb.	.30	—	.31
Sodium fluoride, commercial	lb.	.14	—	.15
Sodium hyposulphite	100 lb.	3.25	—	3.75
Sodium molybdate, per lb. of Mo	lb.	2.50	—	.....
Sodium nitrate, 95 per cent	100 lb.	4.07½	—	.....
Sodium nitrite	lb.	.13	—	.14
Sodium peroxide	lb.	.25	—	.30
Sodium phosphate	lb.	.03½	—	.03½
Sodium prussiate, yellow	lb.	.22	—	.24
Sodium silicate, liquid (60 deg.)	lb.	.05	—	.05½
Sodium sulphide, 30 per cent, crystals	lb.	.02	—	.02½
Sodium sulphide, 60 per cent, fused	lb.	.04½	—	.05
Sodium sulphite	lb.	.05½	—	.06½
Strontium nitrate	lb.	.25	—	.30
Sulphur chloride, drums	lb.	.07½	—	.09
Sulphur dioxide, liquid, in cylinders	lb.	.12	—	.15
Sulphur, flowers, sublimed	100 lb.	3.05	—	3.15
Sulphur, roll	100 lb.	2.70	—	3.10
Sulphuric, crude	ton	35.00	—	37.50
Tin bichloride, 50 deg	lb.	.27½	—	.28
Tin oxide	lb.	.65	—	.70
Zinc carbonate	lb.	.18	—	.20
Zinc chloride	lb.	.14	—	.14½
Zinc cyanide	lb.	Nominal		
Zinc dust, 350 mesh	lb.	.12	—	.13
Zinc oxide, American process, works	lb.	.10	—	.12
Zinc sulphate	lb.	.03½	—	.04

Coal Tar Products (Crude)

Benzol, pure, water white	gal.	.20	—	.25
Benzol, 90 per cent	gal.	.25	—	.....
Toluol, in tank cars	gal.	.25	—	.....
Toluol, in drums	gal.	.30	—	.35
Xylol, pure, water white	gal.	.45	—	.55
Solvent naphtha, water white	gal.	.20	—	.25
Solvent naphtha, crude, heavy	gal.	.15	—	.17
Creosote oil, 25 per cent	gal.	.45	—	.55
Dip oil, 20 per cent	gal.	.40	—	.45
Pitch, various grades	ton	8.00	—	20.00
Carbolic acid, crude, 95-97 per cent	lb.	Nominal		
Carbolic acid, crude, 50 per cent	lb.	Nominal		
Carbolic acid, crude, 25 per cent	lb.	Nominal		
Cresol, U. S. P	lb.	.18	—	.20

Intermediates, Etc.

Alpha naphthol, crude	lb.	1.00	—	1.10
Alpha naphthol, refined	lb.	1.20	—	1.25
Alpha naphthylamine	lb.	.45	—	.50
Aniline oil, drums extra	lb.	.24	—	.25
Aniline salts	lb.	.36	—	.40
Anthracene, 80 per cent	lb.	.50	—	.55
Benzaldehyde (f.f.c.)	lb.	2.50	—	2.60
Benzidine, base	lb.	1.00	—	1.15
Benzidine, sulphate	lb.	.95	—	1.00
Benzoic acid, U. S. P	lb.	1.20	—	1.25
Benzoate of soda, U. S. P	lb.	1.20	—	1.25
Benzyl chloride	lb.	.50	—	.....
Beta naphthol benzoate	lb.	5.50	—	6.00
Beta naphthol, sublimed	lb.	.55	—	.65
Beta naphthylamine, sublimed	lb.	2.50	—	2.55
Dichlorbenzol	lb.	.15	—	.20
Diethylaniline	lb.	2.25	—	2.75
Dinitrobenzol	lb.	.30	—	.35
Dinitrochlorbenzol	lb.	.30	—	.35
Dinitronaphthaline	lb.	.50	—	.55
Dinitrotoluol	lb.	.40	—	.50
Dinitrophenol	lb.	.38	—	.40
Dimethylaniline	lb.	.55	—	.60
Diphenylamine	lb.	.70	—	.75
H-acid	lb.	2.35	—	2.75
Metaphenylenediamine	lb.	1.55	—	1.75
Monochlorbenzol	lb.	.15	—	.17
Naphthalene, flake	lb.	.07	—	.08
Naphthalene, balls	lb.	.10½	—	.11½
Naphthionic acid, crude	lb.	1.20	—	1.30
Naphthylamin-di-sulphonic acid	lb.	1.00	—	1.10
Nitro naphthaline	lb.	.40	—	.45
Nitro toluol	lb.	.55	—	.60
Ortho-amidophenol	lb.	6.00	—	7.00
Ortho-dichlor-benzol	lb.	.15	—	.20
Ortho-toluidine	lb.	.45	—	.50
Ortho-nitro-toluol	lb.	.45	—	.50
Para-amidophenol, base	lb.	3.25	—	3.65
Para-amidophenol, H. C. L	lb.	3.50	—	3.75
Para-dichlor-benzol	lb.	.15	—	.20
Paranitraniline	lb.	1.25	—	1.35
Para-nitro-toluol	lb.	1.50	—	1.60
Paraphenylenediamine	lb.	3.25	—	3.50
Para toluidine	lb.	1.80	—	1.85
Phthalic acid anhydride	lb.	2.50	—	3.00
Phenol, U. S. P	lb.	Nominal		
Resorcin, technical	lb.	4.50	—	5.00
Resorcin, pure	lb.	7.00	—	8.00
Salicylic acid, U. S. P	lb.	.35	—	.40
Salol	lb.	.95	—	1.00
Sulphanilic acid, crude	lb.	.25	—	.31
Toluidine	lb.	2.45	—	.....
Toluidine-mixture	lb.	.80	—	1.00

Petroleum Oils

Crude (at the Wells)

Pennsylvania	bbl.	4.00	—	.....
Corning, Ohio	bbl.	2.85	—	.....
Somerset, Ky	bbl.	2.60	—	.....
Wooster, Ohio	bbl.	2.85	—	.....
Indiana	bbl.	2.28	—	.....
Illinois	bbl.	2.25	—	.....
Oklahoma and Kansas	bbl.	2.25	—	.....
Caddo, La., light	bbl.	2.10	—	2.25
Corsicana, Tex., light	bbl.	2.25	—	.....
California	bbl.	1.24	—	1.57
Gulf Coast	bbl.	1.25	—	1.30
Mexican	bbl.	1.90	—	.....

Fuel Oil

New York	gal.	.15	—	.....
Philadelphia	gal.	.10½	—	.....
Baltimore	gal.	.07½	—	.15
Pittsburgh	gal.	.07½	—	.10½
Texas	bbl.	1.85	—	2.10
Los Angeles	bbl.	1.65	—	.....

Gasoline (Wholesale)

New York, motor	gal.	.24½	—	.....
Gas machine	gal.	.41½	—	.....
72-76 degrees	gal.	.33½	—	.39½
70-72 degrees	gal.	.32	—	.37½
67-70 degrees	gal.	.30½	—	.36½
Pittsburgh, motor	gal.	.24½	—	.....
Chicago, motor	gal.	.23	—	.....
Oklahoma, motor	gal.	.23½	—	.....
San Francisco, motor	gal.	.20½	—	.....

Paraffine Waxes

Crude, 103 to 105 deg. m.pt	lb.	.08½	—	.09
Crude, 118 to 120 deg. m.pt	lb.	.09½	—	.10
Crude, 124 to 126 deg. m.pt	lb.	.10	—	.....
Refined, 120 deg. m.pt	lb.	.12	—	.12½
Refined, 128 deg. m.pt	lb.	.14	—	.....
Refined, 135 deg. m.pt	lb.	.15	—	.15½
Refined 140 deg. mp	lb.	.17½	—	.....
Ozokerite, green	lb.	.85	—	.90

Lubricants

Black, reduced, 29 gravity, 25-30 cold test	gal.	.20	—	.30
Cylinder, light	gal.	.38	—	.42
Cylinder, dark	gal.	.39	—	.43
Paraffine, high viscosity	gal.	.40	—	.41
Paraffine, 0.903 sp. gr	gal.	.32	—	.33
Paraffine, 0 865 sp. gr	gal.	.29	—	.35

Flotation Oils

(Prices at New York unless otherwise stated)

Pine oil, crude, f. o. b. Florida	gal.	.44	—	.....
Pine oil, steam distilled, sp. gr. 0.925-0.940	gal.	.58	—	.60
Pine oil, destructively distilled	gal.	.58	—	.60
Pine-tar oil, sp. gr. 1.02-1.035	gal.	.35	—	.....
Pine-tar oil, double refined, sp. gr. 0.965-0.990	gal.	.42	—	.....
Pine-tar oil, ref., light, sp. gr. 0.950, tank cars, f.o.b. works	gal.	.37	—	.....
Pine-tar oil, ref., heavy, sp. gr. 1.025, tank cars, f.o.b. works	gal.	.28	—	.....
Pine-tar oil, ref., thin, sp. gr., 1.060-1.080	gal.	.32	—	.....
Turpentine, crude, sp.gr. 0.870-0.900	gal.	.45	—	.....
Hardwood oil, f.o.b. Michigan, sp.gr. 0.960-0.990	gal.	.23	—	.....
Hardwood oil, f.o.b. Michigan, sp.gr. 1.06-1.08	gal.	.23	—	.....
Wood creosote, ref., f.o.b. Florida	gal.	.31	—	.....

Naval Stores

Rosin A-E barrel	280 lb.	12.20	—	12.30
Rosin F-I	280 lb.	12.35	—	12.80
Rosin K-N	280 lb.	13.50	—	14.50
Rosin WG-W	280 lb.	15.25	—	15.50
Spirits of turpentine	gal.	.75	—	.....
Wood turpentine, steam distilled	gal.	.64	—	.65
Wood turpentine, destructively distilled	gal.	.63	—	.65½
Pitch	bbl. 220 lb.	8.00	—	.....
Tar, kiln dried	280 lb.	13.00	—	13.50
Retort tar	280 lb.	14.00	—	14.50
Rosin oil, first run	gal.	.74	—	.....
Second run	gal.	.76	—	.....
Third run	gal.	.82	—	.....
Fourth run	gal.	.92	—	.....

Vegetable Oils

Castor oil	lb.	.21	—	.29
China wood oil	lb.	.19	—	.21
Cocoanut oil	lb.	.12½	—	.18
Corn oil	lb.	.13	—	.17
Cottonseed oil, crude	lb.	.17½	—	.22
Linseed oil, raw, cara	gal.	1.50	—	1.53
Palm	lb.	.14½	—	.23½
Peanut oil, crude	lb.	.14½	—	.21
Soya bean oil, Manchuria	lb.	.12½	—	.16

Glues

Extra white	lb.	.35	—	.40
Cabinet	lb.	.25	—	.26
Brown foot stock	lb.	.15	—	.19
Fish glue, 50-gal. barrels	gal.	1.00	—	1.50

Miscellaneous Materials

Barytes, floated, white domestic	ton	33.00	—	36.00
Beeswax, white, pure	lb.	.63	—	.65
Beeswax, unbleached	lb.	.40	—	.48
Blanc fixe	lb.	.05½	—	.....
Casein	lb.	.18	—	.22
Chalk, light, precipitated, English	lb.	.04½	—	.06
China clay, imported, lump	ton	20.00	—	40.00
China clay, domestic, lump	ton	15.00	—	22.50
Feldspar	ton	8.00	—	12.00
Fluorspar, gravel, f. o. b. mines	ton	25.00	—	32.00
Fluorspar, washed, powdered	ton	90.00	—	.....
Fuller's earth, powdered	100 lb.	1.50	—	2.00
Graphite Alabama	lb.	.08	—	.12
Ceylon	lb.	.09	—	.22
Madagascar	lb.	.10	—	.15
Mexican	ton	35.00	—	75.00
Japan wax	lb.	.12	—	.14
Orange shellac	lb.	.49	—	.64
Pumice stone	lb.	.04	—	.08
Soapstone	ton	.12	—	.17
Stearic acid	lb.	.17	—	.19½
Talc, American, white	ton	20.00	—	40.00

Refractories, Etc.

(F.O.B. Works)

Chrome brick	net ton	100.00	—	120.00
Chrome cement	net ton	65.00	—	.....
Clay brick, first quality firecla	per 1000	40.00	—	47.00
Clay brick, second quality	per 1000	35.00	—	40.00
Magnesite, raw	ton	30.00	—	35.00
Magnesite, calcined, powdered	ton	50.00	—	65.00
Magnesite, dead burned	net ton	38.00	—	40.00
Magnesia brick, 9x4½x2½	net ton	90.00	—	.....
Silica brick	per 1000	45.00	—	55.00

Ferroalloys

Ferrocarbontitanium, 15-18 per cent, carloads, f. o. b. Niagara Falls, N. Y.	ton	200.00	—	250.00
Ferrocerium	lb.	15.00	—	30.00
Ferrochromium, per lb. of Cr.	lb.	.30	—	.40
Ferromanganese, domestic, 70 per cent basis	ton	150.00	—	.....
Spielgeleisen (16-18%)	ton	45.00	—	50.00
Ferromolybdenum, per lb. of Mo	lb.	3.50	—	4.50
Ferrosilicon, 50 per cent, contract	ton	120.00	—	125.00
Ferrotungsten, 75-85 per cent, f.o.b. Pittsburgh	lb.	Nominal		
Ferrouranium, f.o.b. works, per lb. of U	lb.	7.50	—	.....
Ferrovanadium, f.o.b. works	lb.	.....	—	.....

Ores and Semi-finished Products

Chrome ore, 35%, per unit	ton	.80	—	.....
Chrome, Caledonia, 50%, per unit	ton	1.00	—	.....
Coke	ton	6.00	—	7.00
Petroleum coke	ton	16.00	—	.....
Manganese ore, 48 per cent and over, per unit	ton	1.20	—	.....
Manganese ore, chemical	ton	75.00	—	85.00
Molybdenite, per lb. of MoS_2	lb.	.75	—	.85
Tungsten, Scheelite, per unit of WO_3	ton	10.00	—	12.00
Tungsten, Wolframite, per unit of WO_3	ton	7.00	—	9.00
Uranium oxide, 96%	lb.	3.25	—	3.60
Vanadium pentoxide, 99%	lb.	10.50	—	.....
Pyrites, foreign	unit	.17	—	.....

Plant Supplies

BUILDING MATERIALS

Common clay bricks	M	14.00	—	15.00
Faced brick	M	37.00	—	46.00
Hollow tile, 4x12x12	M	56.00	—	86.00
Hollow tile, 12x12x12	M	162.00	—	218.00
Lime	ton	17.50	—	.....
Portland cement	bbl.	3.45	—	3.62
Single glass (82-lb.), 10x26-16x24		21.00	—	27.00
Double glass (164 lb.), 10x26-16x29		31.00	—	39.00
Yellow pine lumber	M	39.00	—	45.00
Cypress	M	70.00	—	.....
Tarred felt (14-lb. sq.)	ton	52.00	—	55.00
Roofing pitch	ton	18.00	—	22.00
Asphalt coated roofing (35-55-lb.sq.)	sq.	1.60	—	2.45
Slate surfaced asphalt shingles	sq.	5.25	—	5.50
Corrugated galvanized iron	ton	100.00	—	.....
Putty	100 lb.	6.00	—	.....
Red oxide (Fpte. Copperas)	100 lb.	15.00	—	20.00
Native red oxide	100 lb.	3.25	—	5.00

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

DADEVILLE — The Dadeville Naval Stores Co. plans to install a turpentine distillery. J. D. Arnold, Dadeville, interested.

California

FRESNO—The Union Oil Co., Divisadero and Roosevelt Sts., plans to build an addition to its oil distributing plant; also six substations. Estimated cost, $200,000.

LOS ANGELES—The Bonnie-Reed Film Manufacturing Co., Niles, plans to build a motion picture plant, on Sunset Boulevard and Bronson Ave., to include laboratories, power plant, offices, etc. Total estimated cost, $1,000,000. Train & Williams, 225 Exchange Bldg., architect.

PORTERVILLE—The city trustees are having plans prepared by Olmsted & Gillelen, engineers, Hollingsworth Bldg., Los Angeles, for the construction of a gas plant.

RICHMOND—The Standard Oil Co., 200 Bush St., San Francisco, has awarded the contract for the construction of a 3-story laboratory, here, to P. J. Walker & Co., Monadnock Bldg., San Francisco. Estimated cost, $175,000.

VERNON—The Pan-American Petroleum Co., Security Bldg., Los Angeles, will build an oil refinery on a 12-acre site in the industrial district here, for the manufacture of greases and paraffine products. Estimated cost, $250,000. T. D. Boyce, care of company, engineer.

Colorado

EMPIRE—The Empire Gold Mining, Milling & Tunnel Co. plans to build a 50-ton concentrating mill and is in the market for milling plant equipment and lumber. Estimated cost, $50,000. W. A. Snyder, superintendent.

GEORGETOWN—The Georgetown Tunnel & Transportation Co. plans to build a crushing and concentrating mill and is in the market for a crusher, motor concentrating tables, etc. Address C. A. Basse, 608 Dearborn St., Chicago, Ill., secretary.

Connecticut

HARTFORD—The Board of Water Commissioners received bids for the construction of a filtration plant, from the Foundation Co., 233 Broadway, New York City, $627,507; F. T. Ley & Co., 495 Main St., Springfield, Mass., $632,649; H. E. Fox Construction Co., Inc., 81 East 125th St., New York City, $668,955. Noted Feb. 15.

PLAINVILLE—Landers, Frary & Clark, Commercial and Centre Sts., has awarded the contract for the construction of a 4-story, 60 x 100 ft. factory on Woodford Ave., for the manufacture of celluloid, to the Torrington Building Co., 197 Water St., Torrington. Estimated cost, $50,000.

Florida

JACKSONVILLE—The Virginia-Carolina Chemical Co., 11 South 12th St., Richmond, Va., plans to build a modern fertilizer plant on Talleyrand Ave., here. Estimated cost, $200,000.

Illinois

CHICAGO—Armour & Co., Union Stock Yards, has awarded the contract for the construction of a 2-story, 40 x 80 ft. glycerine distilling plant at 1355 West 31st St., to J. L. Carnegie & Sons, 189 West Madison Ave. Estimated cost, $15,000.

CHICAGO—The Peoples Gas, Light & Coke Co., 122 South Michigan Ave., plans to build a gas tank, having a capacity of 50,000,000 cu.ft. of gas per annum, at Crawford Ave. and 36th St. Estimated cost, $15,000,000. R. Schenck, care of owner, engineer.

Indiana

CHESTERTON—The Gary Chemical Co., recently incorporated with $50,000 capital, plans to build a plant for the manufacture of chemicals and medicinal preparations. V. U. Young, Gary, general manager.

EAST CHICAGO—The East Chicago & Indiana Harbor Water Co., 113 Monument Circle, Indianapolis, has awarded the contract for the construction of a new filtration plant, to the Warner Construction Co., 189 West Madison St., Chicago, Ill. Estimated cost, $333,000. Noted Feb. 15.

Kansas

BLUE MOUND—The Commerce Mining & Royalty Co., Miami, Okla., plans to build a sludge mill to handle sand tailings at Webber mine, and is in the market for tables, motor, rolls, elevators and transmission belting. Estimated cost, $10,000. J. Newton, general superintendent.

TREECE—The King Brand Mining Co., Picher, Okla., plans to build a concentrating plant here. Estimated cost, $100,000. W. Landrum, superintendent.

TREECE—The Wachusetts Mining Co., Commerce, Okla., plans to build a mill here. A. Mayerhoff, superintendent.

Maryland

HAGERSTOWN—The Maryland Smelting & Refining Co., West Church St., has awarded the contract for installing a brass-smelting furnace, having 1 ton capacity, a complete metal concentrating plant and metallurgical laboratory, to the Universal Engineering Corp., 1229 Calvert St., Baltimore.

SOLLERS STATION (Sollers P. O.)—The Aluminum Ore Products Co., Inc., 800 Maryland Trust Bldg., Baltimore, plans to enlarge its plant here. Estimated cost, $8,000,000. J. E. Aldred, chairman of the board of directors of the Consolidated Gas, Electric Light & Power Co., Lexington Bldg., Baltimore, interested.

Massachusetts

CHATHAM—The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans to build a septic tank and sewage disposal plant here. Estimated cost, $75,000.

NEW BEDFORD—W. A. Robinson & Co., 144 South Water St., plans to rebuild its plant for the manufacture of oil, recently destroyed by fire, entailing a loss of $75,000.

WORCESTER—The Morgan Spring Co., West Boylston St., plans to build a 1-story, 41 x 80 ft. addition to its main plant to be used as a rolling mill.

Michigan

DETROIT—J. G. Kastler & Co., architects, 523 Chamber of Commerce Bldg., will soon award the contract for the construction of a 2-story, 120 x 150 ft. brass foundry, for Lokomsky Bros., Dubois St. and East Grand Boulevard.

Missouri

PLATTSBURG—The city plans an election soon to vote on a $70,000 bond issue for a new waterworks system. Plans include the construction of a dam and filtration plant, etc.

WACO—The Tulsa-Pittsburg Mining Co., Pittsburg, Kan., plans to move its mill from Diamond and erect same at Waco, and is in the market for boilers, hoist, pumps, rock drills and tables. Estimated cost, $75,000. A. O'Connor, superintendent.

WEBB CITY—Wommack & Co. plans to build a concentrating plant. Estimated cost, $60,000. E. Wommack, superintendent.

Montana

HELENA—The State Legislature has appropriated $50,000 for the construction of a laboratory here for the State Board of Health.

Nebraska

OMAHA—The Skinner Packing Co., 904 First National Bank Bldg., has awarded the contract for the construction of a 6-story, 65 x 65 ft. fertilizer factory, to Collins Bros., Omaha. Estimated cost, $50,000.

OMAHA—The State Legislature, Lincoln, plans to appropriate $40,000 for installing electrical apparatus, laboratory equipment, etc., in the University of Nebraska, College of Medicine, at 42nd St. and Dewey Ave. J. Latenser, 632 Bee Building, architect.

New Jersey

HARRISON—Berkowitz Bros. are having plans prepared by M. J. Nadel, architect, 15 Clinton St., Newark, for the construction of a candle factory on Plane St. Estimated cost, $50,000.

NEWARK—The Miller & Moran Chemical Works, Meadow St. near Lincoln Highway, plans to rebuild its plant, recently destroyed by fire, entailing a loss of $25,000.

New York

BROOKLYN—J. Bene & Sons, 641 Dean St., has had revised plans prepared by M. Freehof, architect, 405 Lexington Ave., New York City, for a 1-story, 100 x 100 ft. chemical factory on Clinton Ave. near Fulton St. Estimated cost, $35,000. Noted Dec. 30.

BROOKLYN—The Beth Moses Hospital, Hart St. and Stuyvesant Ave., will install a laboratory in the 5-story, 90 x 100 ft. addition to the hospital which it plans to build. Total estimated cost, $350,000. H. J. Nurick, 957 Broadway, architect.

CANASTOTA—The city plans election soon to vote on proposition to install sterilization plant.

MIDDLEPORT—The Board of Trustees plans to install a filtration plant and equipment, using the water from the Barge Canal. Estimated cost, $20,000.

OLEAN—J. J. Mahoney, supervisor of health of Cattaraugus and Chautauqua Counties, has petitioned the State Board of Health, Albany, for the construction of a pathological laboratory here.

OLEAN—The United States Glue Co. plans to build a 1-story and 2-story glue manufacturing plant. Estimated cost, $300,000.

UTICA—E. Kemper, city engineer, has completed plans for the construction of a sewage disposal plant to be located in the Sixteenth Ward.

UTICA—The State Hospital Commission, Capitol, Albany, has awarded the contract for the construction of a 2-story, 44 x 60 ft. laboratory and mortuary at the State Hospital, here, to Laporte & Goodman, P. O. Box 284, Albany, $23,900. Noted Feb. 15.

WATERTOWN—The city is having surveys made and plans prepared by E. W. Sayles, city engineer, for the construction of a sewage disposal plant in the Eighth Ward.

WATERTOWN—The Water Board plans to equip a purification and pumping station with apparatus for making water analysis and alum tests. J. W. Phippen, superintendent.

WILLARD—The New York State Hospital Commission, Capitol, Albany, will receive bids until April 9 for the construction of a chlorinating plant at the Willard State Hospital here. F. L. Warne, steward, L. F. Pilcher, state architect. Noted March 15.

Ohio

FINDLAY—The State Board of Health, Columbus, has ordered the city to build a sewage treatment plant. U. K. Stringfellow, city engineer.

FREMONT—The city plans to build a filtration plant. Estimated cost, $90,000. G. W. Lesher, city engineer.

NORWALK—The State Board of Health has ordered the city to build a sewage disposal plant. C. W. Anderson, mayor.

PAULDING—The city plans to purchase chemical equipment for the local fire department.

TOLEDO—F. S. Royster Guano Co., 813 Second National Bank Bldg., plans to build a sulphuric acid plant on a 5-acre site adjoining its fertilizer factor on Stickney Ave. Estimated cost, $500,000.

TOLEDO—The Standard Oil Co. of Ohio, Gas Bldg., Cleveland, has purchased a site of 810 acres northeast of the city and is having plans prepared for the construction of twenty-four crude oil stills, twelve running stills, eighty pressure stills, and from twelve to twenty-four other stills, steel storage tanks, warehouses, etc. Estimated cost, between $4,000,000 and $5,000,000.

WAUSEON—The city plans an election about May 1 to vote on a $170,000 bond issue for the construction of a filtration plant, pipe lines and an 80,000,000-gal. capacity impounding reservoir. W. J. Sherman, 613 Nasby Bldg., Toledo, engineer.

Oklahoma

BURKBURNETT—The Interstate Refining Co., recently organized, plans to build an oil refinery here, having a capacity of 1500 bbl. J. A. Jones, president.

PICHER—The Beck Mining Co. plans to move its mill from Quapaw field and erect same at Picher, and is in the market for hoists, rock drills, tubs and ground cars. Estimated cost, $75,000. A. Beck, general manager.

Oregon

GASCO—The Portland Gas & Coke Co., Gasco Building, Portland, has awarded the contract for the construction of an extension to its gas plant here, to O. R. Wayman, 939 Thurman St., Portland. Estimated cost, $15,000.

PORTLAND — The Pfister & Vogel Leather Co., 443 Virginia St., plans to build a 7-story, 100 x 125 ft. addition to its tannery. Estimated cost, $125,000. C. P. Bossert, engineer, care of company, is receiving bids.

Texas

BIRDVILLE—The Ok-In Producing & Refining Co. plans to build an oil refinery here, having a daily capacity of 5000 bbl. Estimated cost, $250,000. G. W. Merrill, Ft. Worth, president.

BURKBURNETT—The Meridian Gasoline Co. plans to build a casinghead gasoline plant. W. K. Campbell, president.

EL PASO—The El Paso County Medical Society plans to build a 6-story office building at Mesa Ave. and Franklin St. Plans include the installation of community laboratories, operating rooms, etc.

FT. WORTH—The Eldorado Refining Co., Eldorado, Kan., plans to build an oil refinery here, having a daily capacity of 5000 barrels.

FT. WORTH—The Home Oil & Refining Co., recently incorporated with $5,000,000 capital, has awarded the contract for the construction of a refinery, to W. C. Hedrick Construction Co., Ft. Worth National Bank Bldg. W. M. Babcock, 1119 North Main St., Tulsa, Okla., president.

FT. WORTH—The Texas Producing & Refining Co., recently incorporated with $2,000,000 capital, plans to build an oil refinery. W. H. Newberry, Childress, and J. Gee, Ft. Worth, interested.

HOUSTON—The Humble Oil & Refining Co., 1019 Main St., plans to build a 10,000-bbl. lubricating oil plant on the ship channel near here. Estimated cost, $2,000,000.

WICHITA FALLS—The New-Tex Refining Co. plans to build an oil refinery, having a capacity of 2000 bbl. E. B. Bailey, president.

Utah

SALT LAKE—The General Reduction & Chemical Co., 23 West 2nd St., plans to build a plant for the manufacture of sulphuric, nitric, hydrochloric and other acids. Estimated cost, $250,000.

Wisconsin

BUTTE DES MORTS—The Peerless Paper Products Co., Menasha, has purchased a site on Little Lake, near here, and plans to build a new pump and paper mill. Estimated cost, $100,000. T. E. McGillan, general manager.

GREEN BAY—The Ft. Howard Paper Mill, recently organized, plans to build a paper mill. Estimated cost, $200,000. A. Cafvin, manager.

MENASHA—The Peerless Paper Products Co., Manitowoc St., is having plans prepared by L. A. De Guere, engineer, Wood County Bank Bldg., Grand Rapids, for the construction of a 3-story, 40 x 150 ft. paper mill.

SHEBOYGAN—The American Hide Co., 1102 Wisconsin Ave., has awarded the contract for the construction of a 4-story tannery on South Water and Wisconsin Ave., to Morris Shukdart. Estimated cost, $8750.

SHEBOYGAN—Juul & Smith, architects, 805 North 8th St., will receive bids until April 15, for the construction of a 4-story, 100 x 250 ft. tannery on Illinois and Water St., for the Badger State Tannery Co. Estimated cost, $45,000.

Ontario

GUELPH—James, Loudon & Hertzberg, engineers, Excelsior Life Bldg., Toronto, will receive bids in about five weeks for the construction of a 4-story, 80 x 200 ft. factory on Metcalf St., for the Premier Rubber Co. Estimated cost, $135,000.

KITCHENER—The Kaufman Rubber Co., 419 King St., plans to build an addition to its plant. Estimated cost, $40,000. A. R. Kaufman, manager.

OTTAWA—The Y. M. C. A., Metcalfe St., plans to build a mechanical filtration plant to filter 30,000 gal. of water for a swimming tank. G. Crain, president.

ROCKLAND—W. C. Edwards & Co., Ltd., Sussex St., Ottawa, will soon receive bids for the construction of a pulp and paper mill here. Estimated cost, $3,600,000.

Quebec

THREE RIVERS — The International Paper Co., 30 Broad St., New York City, N. Y., plans to build a 1- and 2-story paper plant here. Estimated cost, $3,000,000.

Saskatchewan

REGINA—The Continental Oil Co. plans to build an oil refinery here. Estimated cost, $1,000,000. A. B. Allen, local manager.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold a meeting at 29 S. LaSalle St., Chicago, May 13 and 14.

THE AMERICAN CHEMICAL SOCIETY will hold a meeting in Buffalo, April 7 to 11.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its annual meeting in New York City from April 3 to 5.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 22nd annual meeting at Atlantic City, N. J., June 24-27. The headquarters will be at the Hotel Traymore.

THE AMERICAN ZINC INSTITUTE will hold its annual meeting at St. Louis, Mo., May 12.

THE NATIONAL FOREIGN TRADE COUNCIL will hold its sixth National Foreign Trade Council at the Congress Hotel, Chicago, Ill., on Thursday, Friday and Saturday, April 24, 25 and 26, 1919.

THE NATIONAL SERVICE COMMITTEE of the Engineering Council will hold a meeting at Chicago, Ill., April 23 to 25.

THE NEW JERSEY CHEMICAL SOCIETY will hold a meeting in Newark on April 7.

Industrial Notes

THE COMMONWEALTH SILICA CO., Ottawa, Ill., producer of sand for iron and steel manufacturing purposes, has recently purchased the property of the Ottawa Steel Molding Sand Co., which has 84 acres of "Buffalo Rock" land and all equipments.

THE COE-STAPLEY MFG. CO., formerly at 135 Broadway, New York, is now located at 136 Liberty Street.

THE TOLLAND MFG. CO., Montreal, Can., has recently placed on the market a metal known as "Tamco," which is particularly adapted for rolling mill and all other bearings subject to heavy pressure.

THE OHIO METAL BRIQUETTING CO., Cleveland, Ohio, has placed a contract with the Crowell-Lundoff-Little Co. for a new plant for manufacturing briquets of scrap metal. Annealing furnaces and some other equipment will be required.

THE COMMERCIAL AND INDUSTRIAL BUREAU OF THE POLISH NATIONAL DEPARTMENT has been organized for the purpose of re-establishing commercial relations between the United States and Poland. It will collect all data and information to form a basis for the work of the future official Polish agencies in this country. The Bureau will be glad to furnish information concerning trade conditions and business opportunities in Poland and will also direct individuals and organizations desirous of getting in contact with the Polish market. The Bureau is established at 1032 Aeolian Building, 33 West 42nd St., New York City.

THE NATIONAL ANILINE & CHEMICAL CO., INC., New York, N. Y., announces a new product of its factories in Niagara Blue B R. It is identical with Diamine Blue B X and Benzo Blue B X, which were formerly imported. These prototypes were some of the most widely used brands of Direct Blue, and were put to many special uses.

THE WRIGHT CHEMICAL CORPORATION is enlarging its plant for the manufacture of dyes, intermediates and other chemicals, among which are sulphur colors, dinitrophenol, dinitrochlorbenzol, indophenol, para amidophenol base, para amidophenol and hydrochloride. Mr. A. A. Matheson, who recently resigned as general manager of the Union Dye & Chemical Corp., Kingsport, Tenn., has been elected president of the Wright concern, succeeding Mr. E. J. Wright, who is now vice-president. Mr. A. E. Crocker continues as treasurer. The plant of the Wright Chemical Corp. is at Springfield, N. J., and the office at 38 Park Row, N. Y. C.

TATE-JONES & CO., INC., furnace engineers, Pittsburgh, Pa., announced that after Feb. 1, 1919, Mr. Edward S. Davis will act as district manager, directing sales and service in the Chicago district, with offices located at 931 Monadnock Bldg., Chicago, Ill. Mr. Davis has returned to the company after six months of service as chief, Fuel Oil Section, Bureau of Oil Conservation, United States Fuel Administration.

SCHAEFFER & BUDENBERG, Brooklyn, N. Y., announce the establishment of a selling office at Tulsa, Okla. Mr. T. C. Eales has been appointed as district manager.

FREYN BRASSERT & CO., engineers, Peoples Gas Bldg., Chicago, Ill., announce the appointment of Mr. Wyman Eaton as chief engineer, taking effect Feb. 15, 1919. Mr. Eaton recently resigned as engineer in charge of rolling mill work of the Mesta Machine Co. to take up his new duties.

WALLACE & TIERNAN CO., INC., 349 Broadway, New York City, manufacturers of W & T chlorinating apparatus, have recently appointed Mr. David Morey, Jr., Southwestern representative. Mr. Morey is located at 507 Scollard Bldg., Dallas, Texas.

WARREN WEBSTER & CO., Camden, N. J., announce the opening of a Texas office at 805 Sumpter Bldg., Dallas, Texas, with Mr. W. B. Irwin in charge as district representative.

EPPING-CARPENTER PUMP CO., Pittsburgh, Pa., announce that Mr. Theodore R. Hermansen, formerly of the Harrison Works of the Worthington Pump & Machinery Corp., has become associated with them as works manager.

WESTINGHOUSE CHURCH KERR & CO., INC., announce the opening of an office in the Western Indemnity Bldg., Dallas, Texas, in charge of Mr. A. W. Nichols.

THE NEW JERSEY ZINC CO., New York, had Mr. C. A. Stedman invite a score of the business press representatives to look over its building at 160 Fulton St. Excellent views of their operations were illustrated by motion pictures, after which the applications of zinc were shown. Hinges, doorknobs, doors, electric lamps, wastebaskets, desk sets, ornamental castings and innumerable articles of practical use were shown. All agreed that zinc takes a more beautiful metal finish than brass or bronze. No doubt manufacturers expecting to establish Asiatic trade will do well to promote zinc ware there, as those who like the silvery moon finish will be delighted with zinc products.

THE ELYRIA ENAMELED PRODUCTS CO., Elyria, Ohio, has recently added to its technical force Mr. William H. Jackson, who will serve as engineering assistant to the plant superintendent, and Mr. Max Donauer, who will co-operate with the sales and chemical departments in the application of glass enameled equipment to the chemical industry.

ARTHUR D. LITTLE, INC., Cambridge, Mass., announces that Mr. Herbert L. Sherman, formerly president of the New England Bureau of Tests, Inc., and more recently in charge of inspection for the Construction Division of the United States Army, has joined the corporation, and will be in charge of the department for the testing and inspection of structural materials.

SILL & SILL, 1011 Figueroa St., Los Angeles, Calif., are equipping new offices at the foregoing address and installing complete laboratory equipment for ore testing.

THE CHICAGO PNEUMATIC TOOL CO., Chicago, Ill., has opened offices and warehouses at Tulsa, Okla. and El Dorado, Kansas. The Boston office has recently been removed to 182 High St., in charge of Mr. F. S. Eggleston, district manager of sales. The Detroit office has been moved from 236 Hancock Ave. to 502 Farwell Bldg. The following changes in the staff are announced: Mr. J. I. Edwards has been appointed as manager rock drill sales division, succeeding Mr. E. Eklund, who has been appointed special foreign representative. Mr. Fred H. Waldron, formerly Minneapolis representative, has been appointed

manager pneumatic tool sales division, succeeding Mr. J. G. Osgood, resigned. Mr. Nelson E. Gatch has been made district manager of sales at Minneapolis, with offices at 301 Metropolitan Bank Bldg. Mr. J. K. Haigh has been made assistant district manager of sales in the San Francisco office at 175 First Street.

PAUL O. ABBE, INC., is the title of the new organization created to succeed the business of Paul O. Abbe. The new corporation has purchased a site on which new buildings are being erected to afford increased manufacturing facilities. Mr. Henry Selman, one of the original inventors and developers of the grinding mill, is associated with the new corporation.

THE ELECTRIC FURNACE CONSTRUCTION Co.'s president, Mr. Frank Hodson, returned from Europe Feb. 24, accompanied by Mr. Mr. Harry Etchells, one of the inventors of the "Greaves-Etchells" furnace. Mr. Etchells, during his short stay in America, is to act in an advisory capacity on the latest European practice.

THE AMERICAN STEAM CONVEYOR CORP., Chicago, Ill., announces the appointment of Mr. C. E. Hague as sales manager. Mr. Hague was formerly production engineer of the Mid-West Engine Co., Indianapolis, Ind.

MURPHY & BREWSTER, 40 Cedar St., New York City, announce that Mr. John D. Lyman, formerly sales manager of the Edison International Corp., has been associated with them since March 1, 1919.

THE ELECTRIC FURNACE Co., Alliance, Ohio, has under construction ten Baily electric brass furnaces at the Salem plant to fill a Mexican contract and other similar domestic and foreign orders. This company has just closed a contract to ship to Mexico complete Baily electric furnace equipment for melting brass. The furnaces are of the tilting type, and are rated at 105 kw. electrical capacity, 1500 lb. hearth capacity and a melting rate of 600 lb. per hour.

THE PULVERIZED FUEL EQUIPMENT CORP. has recently been organized for the purpose of taking over the business of the Locomotive Pulverized Fuel Co., and to broaden the activities of the latter to cover the central power station, metallurgical and industrial fields. The head offices are at 30 Church Street, New York City, with a Canadian office in the Transportation Bldg., Montreal. The officers of the Pulverized Fuel Equipment Corp. will be J. S. Coffin, chairman; J. E. Muhlfeld, president; H. F. Ball, vice-president executive, H. D. Savage, vice-president in charge of sales; V. Z. Caracristi, vice-president in charge of engineering, and Samuel G. Allen, secretary-treasurer.

THE ELECTRICAL STEEL Co. OF INDIANA, Indianapolis, Ind., recently completed the addition to its foundry immediately adjacent to the Heroult electric furnace to house a chemical laboratory. The addition consists of a detached I-story building, and is fully equipped with complete chemical apparatus for the analysis of melting stocks and alloys and for the determination of preliminary and final tests of the product of high-grade electric steel castings. In addition to providing for accurate chemical control arrangements have been made for photographic work.

Manufacturers' Catalogs

W. S. ROCKWELL Co., 50 Church Street, New York, calls attention to Bull. No. 39 on rotary annealing and heat-treating furnaces. The design of the furnace is that of a rotating horizontal cylinder with a refractory or metallic spiral lining, so that when material is charged in bulk into the charging drum at one end it is gradually and automatically conveyed through numerous convolutions and at gradually increasing temperature to the other end, where it is automatically discharged at the exact time that it reaches its required temperature. A concentric hood serves to automatically close the discharge opening except at the lowest point of revolution and time of discharge. The hood also serves to guide the material as it leaves the furnace. The furnace is intended to handle, either for annealing, hardening, tempering, blueing or other heat treatment, any small pieces of like dimensions in either brass, copper, steel or other metals, such as cartridge shells, eyelets, ferrules, buttons, caps, cups, coin blanks, steel balls, saw teeth, tacks, screws, rivets, rings, springs, nuts, punchings, etc.; in fact, any small pieces which will travel freely and pass through the openings without choking them. A table on page 13 shows that the fuel consumption in this rotary furnace is very low indeed, averaging about 250 pounds of heat-treated material to a gallon of oil. The labor cost is also low. A novel heat-treatment chart is shown on page 15. Copies will gladly be sent upon request.

THE DENVER FIRE CLAY Co., Denver, Colo., has issued a pamphlet on its technical service relating to furnaces, refractories, laboratory equipment and chemicals. Bulletin 325, on "China Kilns," is another booklet which has just been issued by this company.

SCHAEFFER & BUDENBERG, Brooklyn, N. Y., illustrates and describes its Columbia recording thermometers in Catalog No. 300, just off the press. This attractive catalog is well illustrated, showing actual installations.

THE BLAW-KNOX Co., Pittsburgh, Pa., calls attention to folders, entitled "Build Your Road With Blawforms," "Blawforms for Road, Sidewalk, Curb, and Curb and Gutter Construction," and also a booklet entitled "Products of the Blaw-Knox Co."

THE JEFFREY MANUFACTURING Co., Columbus, Ohio, has issued a descriptive Catalog, No. 210, on the Jeffrey pivoted bucket carrier, for handling coal, ashes, clinker, etc. The catalog is divided equally in its 96 pages between convincing and keenly illustrated details of the carrier, many interesting exterior and interior pages of large power plant equipments and also reproductions of dimensioned blue prints in actual color of typical views for the various sizes of carrier equipment which should be of interest to the architect and engineer. This company has also gotten out Catalog No. 245, on the Jeffrey type-A shredder, which illustrates and describes in 24 pages its swing hammer shredder. Copies will gladly be sent upon request.

THE STEERE ENGINEERING Co., Detroit, Mich., has issued Bull. No. 37, on gas purification, covering the removal of carbonic acid, hydrogen-sulphide, carbon disulphide, ammonia and cyanamide. The bulletin describes methods of purification with lime and iron oxide.

THE SWENSON EVAPORATOR Co., Chicago, Ill., has prepared a pamphlet on the making of maltose, malt syrups and malt extract with special reference to the conversion of breweries to the manufacture of these materials. The pamphlet describes Swenson equipment suitable for this purpose.

THE DURIRON CASTINGS Co., New York, N. Y., has just published Bull. 103, describing Duriron denitrating towers. The pamphlet consists not only of a description of the denitrating and oxidizing system manufactured by the company, but also a brief treatise on the general principles of denitrating spent acid from nitration processes.

THE NICU STEEL CORP., LTD., Box 128, Welland, Ont., Canada, has received from the press its booklet entitled "Nicu Steel," which is a high-grade alloyed steel able to stand hard usage and rough treatment, viz.: Transmission shafts and gears, crank shafts, axles, springs, valve stems, rods, etc. This company has a New York office at 43 Exchange Place.

THE QUIGLEY FURNACE SPECIALTIES Co., INC., New York City, illustrates and describes in Bull. No. 11 the Quigley powdered fuel system for preparing, distributing and burning powdered fuel.

THE J. D. FATE Co., Plymouth, Ohio, has just issued two bulletins on gasoline locomotives. These bulletins show the locomotive in use in various companies.

THE WALTER A. ZELNICKER SUPPLY Co., St. Louis, Mo., announces that its Bull. No. 260, on steel sheet piling, is ready for distribution.

THE AIR REDUCTION Co., INC., 120 Broadway, N. Y., has issued folders which show the benefits derived from the use of Airco products and methods, both for the purpose of building up worn frogs and repairing damaged locomotive cylinders.

ADAM HILGER, LTD., 75A Camden Road, London, N. W. 1, England, calls attention to an attractive booklet on Abbe refractometer with water jacketed prisms, and also a booklet on the Hilger wavelength spectrometer (constant deviation type) and the Nutting photometer.

THE SCIENTIFIC MATERIALS Co., Pittsburgh, Pa., recently issued a pamphlet on American Medical museum jars, which it designed and patented.

THE DEISTER CONCENTRATOR Co., Fort Wayne, Ind., has issued a special bulletin dealing with the No. 7 diagonal deck coal washing table.

THE HENDRICK MANUFACTURING Co., Carbondale, Penn., has just received from the press an attractive 128-page catalog entitled "Perforated Metals." It illustrates the various designs of screen plates, manufactured screens, elevator buckets, conveyor trough and flights, and general sheet and light structural work.

THE LAWRENCE PUMP & ENGINE Co., Lawrence, Mass.: Catalog "C" illustrates and describes centrifugal pumps.

THE GRISCON-RUSSELL Co., 90 West St., New York, calls attention to Bull. 609, on Reilly multiscreen feed water filter and grease extractor.

THE LEEDS & NORTHRUP Co., Philadelphia, Pa., has just issued a new bulletin entitled "Checking Thermocouple Pyrometers." It discusses the importance of maintaining standards and of checking in pyrometry. It points out sources of error and the remedies for troubles in theremocouples, millivoltmeters, cold junctions and potentiometers. It outlines a commercial checking laboratory, including a special checking furnace, precision potentiometers and standardized thermocouples.

The Passing Of a Friend

IN THE passing of J. E. JOHNSON, JR., we sustain a personal as well as a professional loss. For him we could have wished a more peaceful transition instead of the sudden and accidental death which resulted from being struck by an automobile. For him also we should have desired most earnestly a longer life, well rounded in experience and rich in the honors which inevitably would have come later to one who earned them by sheer merit in his earlier years. The morning and noontide of his life were inspiring, filled with the joy of achievement; that there should have been no afternoon and twilight years, with a peaceful setting of the sun, fills one with pity and regret.

In personality MR. JOHNSON was a virile, dynamic force. Always incisive and direct, he had opinions, expressed them forcibly, and left no doubt as to where he stood. Professionally he made an impression which will be felt and recognized more and more as the years go by. Readers of this journal will recall his serial contributions on the iron blast-furnace and the smelting of iron, which later appeared in book form. To his ability there is ample testimony in the mouths of leaders in the profession, from one of whom, MR. BRADLEY STOUGHTON, we are glad to receive and publish elsewhere in this issue a sincere appreciation.

Wanted: A Guardian For the United States

WRITING in the March *Atlantic* under the title "Developing the Estate," MR. ARTHUR D. LITTLE portrays the American people and their country in terms of an old homestead, heavily mortgaged but rich in resources that need intelligent and conservative development. The picture is alluring as we contemplate the "aggregation of undeveloped empires" which constitute our United States, but also appalling when we are reminded of the "long riot of waste and destruction" that has characterized the handling of our estate. The article makes wholesome reading, and it should be widely circulated for the influence it will have in creating a public conscience on a subject too little understood.

As we see it, the duty of creating this conscience devolves squarely upon scientists and technologists. As long as the people see in a lump of coal only a piece of dirty fuel, so long will they handle it wastefully and refrain from protesting against extravagant and uneconomical use. But let them visualize the vast chemical cosmos that exists in that same lump of dirty fuel —the potential heat, light, power, dyes, explosives, medicines and what not—and then realize that our supplies are not limitless, and we will have a moral force that will not tolerate prodigal waste. But who shall

give the people this new vision if not the men of science to whom the facts are known? Similarly we need to be aroused to a lively sense of our timber waste, our low agricultural yields, our undeveloped water power and the importance of all these things to each of us. Really, the problem of reconstruction, of which we have had so much aimless and fruitless talk, becomes a question of intelligent development of our estate.

MR. LITTLE leaves one with the impression that UNCLE SAM needs a guardian in the form of an economic commission to administer the estate and see that the people get the most out of it. The suggestion is a large one and particularly timely, for co-ordinated development is the order of the day in smaller things and should be applicable on a national scale. We are glad to lend our support to the idea.

Railroads and Industrial Research

A CORRESPONDENT takes us to task for chiding the Railroad Administration on its failure to support industrial research as developed under private ownership. "Has it not occurred to you," he says, "that a man holding a bear by the tail, wishing he might let go, but afraid to do so, has no time to think of methods of animal training whereby the bear might be improved?" We confess to a mental lapse. In our zeal for the support of industrial development we overlooked the Administration's predicament. With a rapidly and steadily accumulating deficit instead of the promised surplus, it faces the unpleasant duty of raising rates and thus increasing simultaneously its revenue and unpopularity. Its earnest desire undoubtedly is to get the companies in such shape that it can relinquish its hold and pass them back to the owners—a consummation devoutly to be wished. When that time comes we can expect further attention to industrial research and development which has contributed so much to the country's prosperity.

Chemical Industry And the Victory Loan

SOME months ago we hazarded the opinion that the fourth Liberty loan would be a Victory loan, and so it proved in effect. But the expenses of making war on a huge scale were not to be stopped with the arrangement of an armistice, and so the Government finds it necessary to float a Victory loan this month.

The chemical industry has a peculiar interest in this loan, because in the act of Congress authorizing the Secretary of the Treasury to issue the notes it was provided that $1,000,000,000 should be utilized in extending credits to firms desiring to develop South American markets. Moreover, it was provided that this credit might also be extended to banks and trust companies for use in financing such trade.

We feel quite certain that the German hold on the chemical markets of the United States has been broken by the Allied victory; and thanks to the activity of the Alien Property Custodian, the German-controlled chemical firms in this country have been transferred to American buyers. The domestic field is again open to the local industry. But a domestic field is not going to be large enough to absorb our products, and foreign markets must be opened, exploited and held. The infant chemical industry of the United States can scarcely expect to invade Germany; and England, France and Italy will not permit much European competition from American chemists. South America, however, will be open to us. The former German hold there has been shaken, and in the next decade South America will be one of the important commercial battlegrounds of the world. With the financial aid promised from this Victory loan, it would seem as though American chemical industry should secure its full share of the business in the southern markets. For this reason chemists everywhere should take not only a vital interest in the success of the loan but also an active part in the campaign.

The Philosophy of Buying At Present High Prices

PROFESSOR IRVING FISHER of Yale University made an address before the Conference of Governors and Mayors at the White House on March 3-5, on "The New Price Revolution." The substance of his address was that prices have gone up for keeps, and there's no use waiting for them to go down, because they will not. Business, he said, is stalled and depression threatens because, well, to use a familiar expression which Dr. Fisher didn't, business is on the spring-board, swinging its arms but afraid to jump in. The merchant, he said, is selling, but not buying. The belief that prices will drop is putting a brake upon the entire machinery of production and distribution. Readjustment waits, because we keep on waiting for it.

The speaker is a man of vision and ingenuity, and he is very often right. He insists that we are on a permanent higher price-level, and he holds that the sooner the business men of the country take this view and adjust themselves to it the sooner will they save themselves and the nation from the misfortune which will come if we persist in the present false hope. The general level of prices, he says, is dependent upon the volume and rapidity of the turnover of the circulating medium in relation to the business transacted by it. "If the number of dollars," he explains, "circulated by cash and by check doubles, while the number of goods and services exchanged thereby remains constant, prices will be about double."

This seems to us a good definition of high prices, rather than an explanation of how they came about, but he adds that new money is what causes the increase. He notes the price revolution in the Sixteenth Century, due to the influx of gold and silver from the New World. Prices went way up, and people talked then of a temporary inflation, just as they do now. Similar sequelæ attended the increases in gold production in 1896 and 1914.

We have not space to include his review of the credit situation, except to note that the gold supply of the United States as a basis for credit has increased to such an extent that the ratio of gold to credit has risen since 1914 from 9.6 per cent to 15.3 per cent. The credit instruments of 1918 he records at $11,700,000,000, and notes that there is free gold to support a superstructure of 70 per cent as large as the existing one. He claims that the gold will not return to circulation, nor will there be a great outflow of gold through international trade. The hope that a resumption of international trade will lower prices is found to be false because European prices have risen more than ours, and they are no more likely to fall there than here.

DR. FISHER holds that there will be a vast increase of deposit banking in Europe; that the war has already brought money out of hoardings and into banks. A

consequent expansion of media of exchange will therefore take place, even in such faraway countries as India and China, which means a new habit leading to credit expansion and higher prices. This discovery of deposit banking in these countries is equivalent, economically, to a new source of gold supply.

Finally, DR. FISHER holds that to talk reverently of 1913-14 prices to-day is to speak a dead language; that new price-levels are a stubborn reality, and that the sooner merchants and manufacturers begin to stock up the better it will be all round.

Chemistry, Metallurgy, And the High Cost of Living

THE complexity of modern life and the interdependence of science and industry make it difficult at times to segregate cause and effect or see their true relation. We cannot escape, however, the close connection among chemistry, metallurgy and the cost of our daily food, nor the responsibility that devolves upon representatives of those sciences in contributing to human welfare and happiness. President TONE did well, in his address as retiring president of the American Electrochemical Society, to direct attention to the human aspects of electrochemistry, for in the last analysis the success of that or any other industry lies in the degree to which it satisfies human desires or makes possible the wider enjoyment of the fruits of labor.

The situation may be illustrated with one or two instances that will make clear our obligation. Modern agriculture calls for more intensive cultivation of the land and a larger unit yield of crops. This means artificial fertilization and the substitution of mechanical for horse or man power. It means fixed nitrogen and tractors, available phosphate and rapid transportation, potash and electrical devices. It means chemistry, electrochemistry, metallurgy and electrometallurgy moving together hand in hand, ramifying throughout the entire agricultural industry. Upon the chemist and electrochemist devolves the duty of so perfecting the processes of making fertilizer that it will be cheap enough for widespread use. Upon the metallurgist and electrometallurgist must fall the burden of providing machinery makers with metals and alloys that are at once light, strong and inexpensive so that mechanical devices will become the farmer's common servants. With cheap fertilizer yielding increased crops at lower unit costs, and power appliances replacing the efforts of many men, food must appear in increased abundance and cost less to the consumer. Thus the cycle of achievement and service is completed, and the common good advanced.

A Resolution Of Forces

IT IS interesting to note how many of the after-war problems can be viewed as a resolution of forces, old forces being in play as well as many new ones. The steel industry is seeking an alignment, which will be the resultant of various forces. The ultimate value of the dollar will be the resultant of very many forces.

In the steel industry an ethical question has been presented: Who shall take responsibility for the overhead? The Redfield board, faced with some "cost sheets," decided that certain prices for finished steel, including rails, were fair. The Railroad Administration, presumably by having scrutinized reports of steel company earnings in 1918, regarded the prices submitted as altogether too high. Anticipating a period of relatively light demand for steel, the steel producers desired prices that would take care of their overhead, just as they did in 1908, while the Government is interested in seeing a maximum amount of labor engaged in productive occupation.

In the matter of steel prices there are forces pulling in diametrically opposite directions, and that is true not only of steel but of many other commodities. On the one hand there is a low purchasing power for the dollar, whereby it costs a great deal, measured in dollars, to produce steel. On the other hand there is a great mass of equipment in the United States, in bridges, buildings, factories, transportation systems and other things, which cost certain amounts to establish, measured in the old value of the dollar. If the value of these facilities is to be measured only by the same number of dollars as formerly, then there is little opportunity for the investor to create new facilities to compete with the old, as his investment will be so much greater. Hence he is indisposed to buy steel, and there is a force tending to bring down construction costs so as to make the competition feasible, in other words to increase the purchasing power of the dollar, while on the other hand there is a force tending to increase the nominal value of the facilities existing, whereby they will be valued by a larger number of the existing dollars than formerly. The situation is so plainly recognized that many corporations have only been awaiting a decision of the Supreme Court as to the taxability of stock dividends, in order to decide whether they shall issue such stock dividends, whereby the number of dollars to be represented by the plant investment would be increased, and with the same dividend rate a larger number of dollars would be distributed to the individual stockholder, each of which dollars would buy less, when the stockholder spends it, than before the war. The alternative, to pay much larger percentage dividends, is naturally not favored, as likely to arouse criticism on the part of those indisposed to admit that the lowering of the dollar's value is permanent, or who know nothing about such economic questions.

There must be an adjustment whereby the purchasing power of the dollar and its intrinsic value will be identical. Property values will increase to an extent, while commodities, labor, the ephemeral things that are bought, will decline. When harmony is established, or the forces are resolved, the adjustment will not be permanent. The experience after the Civil War is particularly instructive. An adjustment was reached, which lasted for several years, but there was extravagance, too much conversion of liquid into fixed capital for the permanent requirements of the country, and eventually a five years' industrial depression of great severity set up a new standard, which was too far in the opposite direction. There are quickly acting and slowly acting forces. Those who now think it will require a long time to readjust, to reconstruct the economics of things so that business will function, will be surprised at the shortness of the time, while those who feel that everything can be readjusted in short order will have their surprise later, when they find that the readjustment does not prove permanent, that slowly acting forces get in their work through a period of years.

Readers' Views and Comments

The Bradford Process of Preferential Flotation

To the Editor of Chemical & Metallurgical Engineering

SIR:—The recent article of Mr. Guy C. Riddell[1] on the Bradford process of preferential flotation prompts me to make a few remarks concerning the theory of his process. The facts are, as brought out in the article referred to, that sulphur dioxide does effect a wetting of the sphalerite without any apparent chemical action. since the mineral can be restored to its original condition by subsequent exposure to air or by agitation and aëration after the removal of the sulphur dioxide. It is also true that the effect of this agent is to remove the "gaseous envelope" from the sphalerite, but not from the galena and pyrite. The question of why the sphalerite only is affected has not, however, been answered, and this is the crucial point for any extensions of the process to other minerals or other addition agents. I shall present here a brief theory of this preferential action and indicate the possibilities of extending the process.

To begin with the "gaseous envelope" or adsorbed gas on most minerals with which we have to deal is air. In certain special cases it may be in part sulphur dioxide or hydrogen sulphide, but as the minerals have been generally exposed for considerable time to a gas atmosphere in which the partial pressures of all gases except oxygen and nitrogen are exceedingly small, it is reasonable to assume that these form the normal gaseous envelope. This envelope is the same on all minerals and there is no self-evident reason why sulphur dioxide or other addition agents should remove it from one more than from another. It is true, however, that sphalerite itself is much more soluble than galena or pyrite and hence will react with a bath containing a much lower concentration of acid. We may postulate, then, as the primary preferential reaction

$$ZnS + H_2SO_3 = ZnSO_3 + H_2S$$

or if the bath is acidified with sulphuric acid, the reaction

$$ZnS + H_2SO_4 = ZnSO_4 + H_2S$$

These reactions would not take place with galena or pyrite.

It can now be shown that hydrogen sulphide is adsorbed much more readily by sulphide minerals than is air. Some unpublished experiments of Bajoulian[2] show that galena, sphalerite and chalcocite through 80 mesh take up several times their volume of hydrogen sulphide in a few hours. The hydrogen sulphide liberated by the above given preferential reaction would then displace the adsorbed air and the net effect would be sphalerite with adsorbed hydrogen sulphide and galena and pyrite with adsorbed air. A secondary reaction would then take place by which the hydrogen sulphide would be removed from the sphalerite thus:

$$2H_2S + SO_2 = 2H_2O + 2S$$

The sphalerite would accordingly be maintained without a gaseous envelope and would be unamenable to flotation.

From this explanation it is obvious that a separation of any two sulphide minerals could be effected by using a bath sufficiently acidified to attack one and not the other, and then adding sulphur dioxide or other agent to remove the hydrogen sulphide envelope from the soluble mineral. Unfortunately the difference of solubility of the minerals is not great and they are mostly so insoluble as to require a prohibitive acid concentration.

It is difficult to arrive at any quantitative information regarding the concentration of acid necessary to attack any particular mineral, since the rate of attack is affected by the physical condition of the mineral as well as its solubility. The following table from Weigel[3] gives the solubility of several minerals in water:

Mineral	Mol liter	Gram liter
Galena, from Freiberg	1 21 x 10^{-6}	0 00029
Galena, artificial	1 21 x 10^{-6}	0 00029
Cuprous sulphide, regular	3 1 x 10^{-6}	0 00049
Sphalerite, artificial	6 63 x 10^{-6}	0 00065
Sphalerite, from Satanda	6 65 x 10^{-6}	0 00065
Greenockite	8 99 x 10^{-6}	0 00130
Millerite	16 29 x 10^{-6}	0 00148
Wurtzite	28 32 x 10^{-6}	0 00281
Pyrite, artificial	40 84 x 10^{-6}	0 00490
Pyrite, from Freiberg	48 89 x 10^{-6}	0 00587

The accuracy of these figures is questionable, since they were obtained by conductivity measurements, and it is doubtful if the sulphides dissolve in water without hydrolysis. Certainly the position of pyrite is anomalous, as it is practically unattacked by dilute sulphuric acid, which quickly dissolves sphalerite.

It is possible that an electrochemical action may take place when several minerals are present; at any rate the electromotive series of the minerals seems to more nearly represent their solubility in dilute acid. This series is, according to Gottschalk and Buehler[4]:

Mineral	Volts Against Copper	Mineral	Volts Against Copper
Marcasite	+0.37	Metallic copper	0 0
Chalcopyrite	+0 30	Sphalerite	−0 2
Pyrite	+0 18	Stibnite	−0 2
Galena	+0 15		

According to this series the minerals lower in the table would exert a protective action toward those higher up. Thus in a mixture of pyrite, sphalerite and galena, the sphalerite alone would be dissolved and in fact at a much faster rate than in the absence of the other minerals.

For our purposes we may divide the minerals into two classes, those which give off hydrogen sulphide with dilute acid and those which do not. The following table gives these classes, the data being taken principally from Dana:

MINERALS ATTACKED BY DILUTE ACID		MINERALS NOT ATTACKED BY DILUTE ACID	
Sphalerite	Marcasite	Bismuthinite	Bornite
Greenockite	Zinkenite	Realgar	Chalcopyrite
Stibnite	Jamesonite	Orpiment	Pyrite
Pyrrhotite		Molybdenite	Cobaltite
		Galena	Pyrargyrite
		Argentite	Tetrahedrite
		Chalcocite	Stannite
		Cinnabar	

The minerals which do not give hydrogen sulphide with acids include, of course, also minerals that are not sulphides, and no separation can be made among them by the Bradford process. The minerals which are soluble in dilute acid should, however, be easily separable from one or more of those not soluble. Separation

[1] CHEMICAL & METALLURGICAL ENGINEERING, Dec. 15, 1918.

[2] A thesis done under my direction at the University of Pittsburgh.

[3] *Zeit. Phys. Chem.*, 58, 293 (1967).

[4] Economic Geology, 7, 15 (1912).

among the soluble minerals could also be effected if the right concentration of acid were selected.

Some of the separations suggested as possible by this theory are pyrrhotite from chalcopyrite, pyrrhotite from gold, stibnite from galena, stibnite from sphalerite, sphalerite from greenockite, sphalerite from chalcopyrite, etc.

It is possible to conceive of various extensions to the Bradford process proper; for example, in a mixture of an insoluble sulphide and a mineral other than a sulphide, the two could be treated with hydrogen sulphide and the air on the sulphide mineral displaced, while if the treatment was not too long the air would remain on the other mineral. This mixture should then be separable by the Bradford process.

It should further be possible to replace the sulphur dioxide with any substance that would react rapidly with the hydrogen sulphide. This has been done in Minerals Separation patent 10478 (English), which calls for the use of chlorine or hypochlorites.

Recovery of Potash

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the letter published in your issue of April 1 by Mr. N. H. Gellert in regard to potash recovery, in which Mr. Gellert contrasts the results set forth by Mr. Linn Bradley and myself in our respective articles published in CHEMICAL & METALLURGICAL ENGINEERING of Sept. 26, 1918, I may say that since that date other data have been assembled which show that some of the statements made then by Mr. Bradley and myself should be modified more or less in the light of later results. These modifications would primarily include, (1) cost of operating a Cottrell precipitator, and (2) loss of potash in the slag.

With reference to the cost of operating a Cottrell precipitator at a 200-ton iron blast-furnace, it may be stated that the figures covering operating cost published by Porter[1] for a 3000-bbl. cement plant would apply approximately for a 200-ton iron blast-furnace. Porter's figures, which are quoted in my article referred to by Mr. Gellert, are as follows:

Labor	$27.00	per day
Power	25.00	" "
Repairs	8.00	" "
Laboratory	4.00	" "
Total	$64.00	" "

Total cost per annum $23,360; but let us make it $25,000.

Porter also shows that operating on a mixture averaging about 1 per cent K_2O, on the basis of a selling price of $1 a unit (although present prices are much higher), the operating profit per annum would amount to about $65,300. It would, therefore, be interesting to know how Mr. Gellert gets at his operating cost of $42,000 per annum for a 200-ton blast-furnace. I cannot see that he would employ a larger and more expensive precipitator, more labor, more power, or require more extensive repairs than would be necessary for a precipitator capable of handling the dust of a 3000-bbl. portland cement plant, where the actual operating cost is less than $25,000 per annum. Deducting royalty, however, Mr. Gellert's figures may not appear to be about $17,000 too high, as they would otherwise, estimating, according to his figures, the cost of operating at $42,000; or, $45,000 too high when he estimates that it would amount to $70,000 per annum. It would, therefore, seem to be largely a question of how large a percentage of these figures is assigned to royalty.

In saying this I of course realize that the operating cost of $165,000 given in my article of Sept. 26, 1918, might appear absurdly high, unless it be remembered that these figures also included certain royalties, which were then but tentatively established. Then, too, at that time potash was selling on a $5 per unit basis. Also at that time no continually operating installation of a Cottrell precipitator had been made at any blast-furnace; and these figures were intended to be ultra-conservative, and were based upon investigations, rather uniform and rigid ideas as to royalties, etc., and work done by the Research Corporation. Nevertheless, the present writer at that time accepted these figures, but that he held certain mental reservations concerning them is evidenced by the fact that in the same article he pointed out under "Estimated Costs and Recoveries" the fact that where the materials treated have the same potash tenor, operating costs and recoveries for a 200-ton iron blast-furnace would approximate those of a 3000-bbl. cement plant.

But right here it should be stated that Mr. Gellert's discussion emphasizes—though he doesn't mention it directly—a most important point in regard to royalties in that, as different percentages of recovery would be had in case of variations of potash and other content of different ores, therefore a high and rigid royalty which might readily be paid in one case would not apply in another. This, however, has been recognized and suitable royalty adjustments to fit each particular case have now been made. Data assembled by the present writer since his previous article was written have demonstrated most conclusively the very point that Mr. Gellert brings out, namely, it is not correct to assume that the same percentage of slag "would be potash for different ores." The possibility of the recovery of potash from ores lean in potash is accordingly made much more attractive than but few persons six months ago would have been willing to admit that the data then available indicated. This thought, in which there is possibility of much fallacy and many absurdities, must not, however, be carried too far.

In my article of Sept. 26, Cambrian ores, red ores and brown ores are each treated separately, the idea being to show the yields and results to be anticipated if each ore be employed alone. As a matter of fact, blast-furnace practice in general is to mix either Cambrian gray ores with limey red or Clinton ores, or to mix brown ores with these limey Clinton ores. This general furnace practice is, of course, known to everyone familiar with furnace operation in the South; and hence final results should be sought upon a basis of the proper admixture of red ores with brown, or of red with the Cambrian gray. In this connection it would be interesting to know whether Mr. Gellert's figures are based on any of these admixtures.

Mr. Gellert brings out a point of very great interest when he calls attention to the fact that certain of the brown ores in the South run "about or close to 1½ per

[1] "The Recovery of Potash as a By-Product in the Manufacture of Portland Cement," by John J. Porter, vice-president and general manager of the Security Cement & Lime Co., Hagerstown, Md.

cent potash." If this statement can be shown to apply to any considerable number of important brown ore deposits, the potentialities that would thus be indicated would be very great indeed. It would also be both interesting and well worth while to ascertain the zinc content of these same brown ores.

The present writer regards Mr. Gellert's discussion of the articles referred to as having been most helpful. He finds that he differs from Mr. Gellert chiefly as regards the cost of operating a Cottrell precipitation installation; and although he considers that perhaps Mr. Gellert's figures are too high, at the same time he must himself acknowledge having similarly been in error in presenting without direct criticism the apparently excessively large operating cost to which Mr. Gellert alludes, which cost, though, since it included tentative royalties based on $5 potash, is not really as high as it might at first appear. Naturally, in the light of more recent experience and in the absence of this explanation, the cost referred to is justly open to criticism. Hence it would seem that perhaps both of us might be subject to criticism in the cases here cited for not having itemized our cost, as well as for treating royalties as a part of operating cost, as in the instance just mentioned. My belief is, therefore, that when all these facts are taken into proper consideration our results may really be quite closely in accord. For that reason it seems more advisable to follow Porter's plan as to this, because where different and undesignated royalties are included under operating cost, confusion is almost certain to result, as, for instance, in the case under consideration.

It should always be borne in mind that two royalties are to be included, one for gas cleaning alone and another for valuable products collected. In certain instances the latter may amount to little or nothing, but the service for gas cleaning is always highly valuable. Obviously, though, the royalty for gas cleaning should not be charged against the recovery of valuable by-products, but rather against the cost of furnace operation, since the Cottrell processes make for greatly increased efficiency and economy in furnace operation regardless of the recovery or non-recovery of valuable by-products.

In conclusion, I should say that one of the things which has prevented installation of Cottrell processes at iron blast-furnaces is the widespread impression that the cost of precipitators is very high. According to the Research Corporation, the approximate cost of a precipitator is $1 per cu.ft. of gas treated, making the cost of installation at a 200-ton blast-furnace about $50,000. If electrical equipment be included, the cost of a 2-unit precipitator for a 200-ton blast-furnace would, according to the Research Corporation, "be in the neighborhood of $55,000 to $60,000." We find, however, that by using materials equally as suitable, though less expensive than those called for in the specifications issued by the Research Corporation, the initial cost of a Cottrell installation may be very materially reduced.

On this subject, just as soon as the opportunity is afforded, the present writer will be able to present certain data of a detailed nature which should prove quite helpful to those who plan to make Cottrell installations.

Heat Treating of Shells

To the Editor of Chemical & Metallurgical Engineering

SIR: The paper by Mr. J. M. Hall read before the Steel Treating Research Society at Detroit on heat treatment of shells, reviewed in your Feb. 15, 1919, issue, is a surprise as to its longevity.

The method of treatment should have been challenged in the meeting at the time of the birth of this paper. The treatment could not possibly be applied to 155-mm. high-explosive shell and have a ghost of a chance to pass the physical requirements of the U. S. Ordnance Department, and it is a blessing in disguise it was not widely published in this country, leading American shell manufacturers into trouble by adopting such procedure.

The method is not only extremely crude, but is misleading as well. Heat treating conducted as indicated in the paper permitting a range of temperature for quenching of 200 deg. F. (from 1500 to 1700 F.) and a range of 400 deg. F. (from 950 to 1350 F.) for drawing, on steels having a carbon range of only 0.15 per cent and a manganese range of 0.4 per cent is something unheard of here. It surprises me that even the very liberal British specifications would permit such practice.

Such treatment as that quoted—annealing 60 per cent carbon steel at 1600 deg. F. to reduce the ultimate tensile strength 7000 lb. and increase elongation 6 per cent—is absolutely unreliable and indicates vague knowledge of the condition of the treated steel. The same holds true for the practice of raising the ultimate tensile strength by air cooling from 1550 to 800 deg. F. in 7 minutes. The proper treatment of the steel would have given the desired properties.

Twin City Forge & Foundry Co., Stillwater, Minn. W. J. MERTEN.

Large vs. Small Electric Furnaces

To the Editor of Chemical & Metallurgical Engineering

SIR:—I was much interested in reading Mr. Bardwell's communication in the Dec. 1 issue of this journal on relative efficiencies of various sized electric furnaces, but my experiences do not agree altogether with those published by him. I have in mind two plants, operating 3-phase electric shaft furnaces on the same kind of alloy, one of about 2000-kw. capacity and the other consuming approximately double that amount of energy at a voltage but slightly higher. The average power consumption on the large unit was but 7 per cent less than that of the smaller unit per gross ton of metal produced.

Of course the big problem in the manufacture of ferro-alloys is the reduction of the volatilization losses. Even though the cost of ingredients may not compare with the cost of manganese ore, nevertheless a general reduction in volatilization losses means a corresponding reduction in power input, resulting in a decrease in production cost. However, there are minor problems that are common to most furnace operations and affect the final cost of production in varying degrees. One of these is the reduction of electrode consumption. I wish that Mr. Bardwell had given some data on the variation of electrode consumption with variation of voltage. It is my prediction that with higher voltages, at least up to a certain limit, there will be a decrease in the amount of electrodes used per ton of material produced. R. E. BAKER.

Western Chemical and Metallurgical Field

Working Conditions in the Zinc Smelters of the Gas Belt

HASTILY gathered statistics of zinc smelters in the gas belt (Kansas, Oklahoma and Arkansas) show a present gross retort capacity of about two-thirds the maximum number capable of operation at the peak of war production. Table I gives the figures, the capacity in 1917 being taken from a table published in the *Engineering and Mining Journal*, Vol. 107, p. 58, while the figures for 1919 are approximately correct, an asterisk marking the doubtful entries. The difference between the first and second columns really represents the number of retorts abandoned from a failure of natural gas supplies, while the difference between the second and third columns represents the stagnation in the present zinc market. Hardly one-half of the available retorts are now running, this figure amounting to approximately one-third the number during the war.

Practically all of the operators have been struggling against the inevitable for the last 18 months. During this time the zinc market has been perilously near the cost of production, if not actually below it, with the result that even the most favorably placed works have gradually curtailed. In this period only one plant has added to its capacity, namely, the Athletic Mining & Smelting Co., at Ft. Smith, Ark. The reason why this is true is apparent. Before the war 5c. was considered a fair price for zinc—when it dropped to 4.5c. many of the smelters drew their fires. Taking the reasonable figure of 60 per cent as the increased cost of manufacturing during the last year, the danger point corresponding to 4.5c. is now 7.2c., a figure below which the metal has been for some time.

Smeltermen in the gas belt have shared in the general increase in war-time wages. No general wage scale holds for this region—rates at neighboring plants in the same town may vary as much as 3c. per hour. Thus during 1917, first chargers received anywhere from $3.75 to $5.25 per day, while common labor ranged from $2 to $3. However, in the Tulsa region no less than six increases in wages were posted since May, 1914, increasing that of common labor from $1.75 for 12 hr. to $3.45 for 8 hr., the change in shift being made in July, 1917. Unfortunately these were mostly "flat increases" rather than percentage raises; the result was the reduction of the differential betwen jobs to such a point as to remove the incentive for a workman to take the harder, better or dustier jobs.

Notices of reduction in wages were posted in practically all plants on April 1, ranging from 10 to 15 per cent, in many instances so designed to establish the old differentials between skilled workmen and laborers. Dividing the number of men on a block by their aggregate daily wage, the following rates hold at a representative plant:

Average rate in 1914	$2.285
Rate in January, 1919	4.180
Posted rate April, 1919	3.626

The latter rate is 55 per cent higher than before the war, and represents about the same purchasing power. However, the workday is now universally 8 hours.

Smeltermen at all the unionized plants working under agreements accepted the decrease under protest, and these plants continue, pending an appeal to the national headquarters of the union. However, workmen at the Bartlesville Zinc Co.'s two plants in Bartlesville and at the United States Zinc Co. in Sand Springs have struck, and these plants are now under dead fire. Union organizers are busy and the problem of recognition of the new unions will probably loom larger than wage scales.

TABLE I—ZINC SMELTING CAPACITY IN GAS BELT

Company	Location	Capacity 1917	Capacity 1919	Running March, 1919

Surplus Government Supplies

Copper.—The United Metal Selling Co., representing the copper producers, will sell for the War Department approximately 100,000,000 lb. of copper, at the rate of not less than 5,000,000 lb. per month for a period of ten months and 10,000,000 lb. per month for the next five months. The copper will be sold at market prices, as determined by the average quotations in the *Engineering and Mining Journal*.

Caustic Soda and Soda Ash.—As the surplus of soda ash is only 2,500 tons, this will be sold through the various selling bureaus at current market prices. The amount is so small in comparison with normal consumption that no effect on the trade is anticipated. The surplus caustic soda, 4,000 tons, will probably be disposed of through the manufacturers, so that none will be placed on the market by any of the agencies of the War Department.

Proposed Pan-American Commercial Conference

The Governing Board of the Pan-American Union has voted to hold, under the auspices of the Union, an informal Pan-American Commercial Conference during the last week of May or the first week of June, 1919, in Washington, D. C. It is expected that about 1000 delegates will attend and that the sessions will be addressed by the President, members of his Cabinet, Latin-American Ambassadors and heads of various Government boards and commissions. A complete record of the Conference will be published by the Pan-American Union as a useful handbook of Pan-American trade. The success of a similar conference in 1911 is assurance that the contemplated conference will be a marked success.

JOSEPH ESREY JOHNSON, JR.

An appreciation

By Bradley Stoughton

MR. JOSEPH ESREY JOHNSON, JR., had already gained rare distinction as an able metallurgist, clear thinker, brilliant author and wise consulting engineer to bankers and operators and had achieved the essentials of a great career when death cut short his activities on April 4, 1919, in the forty-ninth year of his age. He belonged to a family of iron blast-furnace men and mine managers. His father, Major J. E. Johnson, after serving with distinction in the Army of the North, identified himself with the iron mines and blast-furnace at Longdale, Va., with which he was connected during almost his entire business life. It is significant that during those troublous times of reconstruction in the South, he enjoyed always the affection and respect of his neighbors and associates alike. From him his son obtained not only a thorough training in blast-furnace practice and iron mining, but great personal courage and force of character. His mother, who survives both her husband and sons, possesses rare intellectuality, humor, and a tenderness and human sympathy which those who were privileged to know well J. E. Johnson, Jr., recognized beneath his exterior of aggressiveness and will power.

JOSEPH ESREY JOHNSON, JR.

In a recently published analysis of the qualities which characterize the world's great men, three traits stand out preëminent, viz., independence, courage and intellectuality. Each of these characteristics J. E. Johnson, Jr., possessed in extraordinary degree. His early education was obtained under a private tutor at Longdale, and this circumstance probably enhanced a natural tendency to independence of character and individuality which, however, under the control of his unusual power of straight thinking and clear analysis never allowed him to go far astray. It has been said of him that if once he set his mind to a problem, however knotty, he scored a bullseye before the subject was dropped.

His manner of attacking a subject involved first mastering the details of the present available knowledge; then putting this acquired information to one side with an untrammeled mind, blazing out a path of his own, so clear, so well-defined, and expressed in such simple terms that he illuminated the whole subject without distorting the original data or discussion. His two books on the iron blast-furnace together form the most comprehensive, the most enlightening, and the most useful treatise on the subject ever produced in any language.

But his ability did not end with the mastery and elucidation of principles enunciated by his predecessors. His own discoveries and inventions in the metallurgy of iron have established his reputation in every civilized country where iron and steel are made. The three most important of these, doubtless, are his thermal theory of the iron blast-furnace, which ranks with Sir Lowthian Bell's chemical practice of the iron blast-furnace as one of the two greatest scientific advances in our knowledge of the art; his original classification of iron and steel as an unbroken series of alloys of iron and carbon; and his discovery that oxide, instead of being the unmixed evil which it was accredited in the minds of most metallurgists, actually benefited the strength of cast iron.

There are many stories told of Esrey Johnson's personal courage, but probably the most spectacular one is the prevention of an attempted lynching in Virginia in 1909. A young white girl had been murdered by a colored boy under those horrifying circumstances with accounts of which we are all too familiar. Johnson was not only manager of the mines and blast-furnace of the locality, but was one of the officials of the county. He organized the search whereby the negro was captured, brought to Johnson's office and a confession of the crime wrung from him. The usual crowd collected quickly, thirsting for vengeance in the form of hanging or burning. Practically alone, Johnson held this crowd at bay for several hours, sometimes mixing with the crowd and pledging his honor that the colored boy should be tried and executed according to law, sometimes pleading for the good name of the community, and when necessary, "showing his teeth" to those who can understand no other argument for the curbing of their personal inclinations or intentions. He has told me that he expressed himself in substantially these words: "I am going to see this nigger hung in accordance with law and order. If you fellows try to prevent me, you may get me, but I will get some of you first." I am sure that at this point in the argument he smiled, for he had a very expressive smile which endeared his friends to him, and which he could make very convincing when he desired. Finally, the morning train arrived on the track just outside Johnson's office. He realized that this was the moment when a coup would be attempted, but he had already laid his plans with the sheriff over the long distance telephone. The train stopped exactly where he had directed. He rushed the trembling culprit by the crowd of angry, heavily-armed men into an empty railroad car occupied only by the sheriff. The door was barricaded behind the three men and the train pulled out before a rush could be accomplished. Another crowd had to be overawed at the entrance of the county courthouse where the judge had called a special term of the court. To him Johnson delivered his prisoner and made good on his promise that justice should be done, which it ultimately was. The story of this interesting episode is told in the *American Law Review* for November-December, 1911, under the title "Lynching Unnecessary."

Johnson led a white life. There was no weak spot in his professional or personal armor of honor and sincerity. His home life was an unusually happy and congenial one. He married Miss Margaret C. Hilles of Wilmington, Delaware, and she was not only his friend and comrade, but an intellectual stimulus and helpmate in a very busy life. She, with one boy, J. E. Johnson, 4th, survives him.

I cannot give a better summary of Johnson's professional attainments than by quoting from a letter from his friend James Gayley. These two master minds found mutual sympathy and understanding. Johnson had an unbounded admiration for Gayley, whom he describes in the dedication of his books as the "founder of modern American blast-furnace practice." Gayley made of Johnson a pupil and gave him valuable advice and assistance during the early days of his establishment as a consulting engineer in New York City. On the day of Johnson's death, Gayley wrote to me as follows:

"American metallurgy of iron has lost its shining light and the world is poorer thereby. . . . Esrey Johnson is and was the greatest man in the metallurgy of iron and the clearest thinker of any man today. He seems like a younger brother gone and none come to fill his place."

Johnson always identified himself with the public work of his profession and community. He was for many years a member of the principal engineering societies, being active in the American Society of Mechanical Engineers, the Mining and Metallurgical Society of America, and the American Institute of Mining and Metallurgical Engineers. His pen has enriched the literature of these and other societies on both sides of the Atlantic. His interests naturally brought him more closely into affiliation with the A. I. M. E., for which he served as a member of the board of directors and chairman and member of many prominent committees, including the vice-chairmanship of the iron and steel committee. Of recent years he had been active in guiding the policies of this Institute, and at the time of his death was, besides a director, a member of the executive committee and chairman of the committee on admissions.

The Engineer as a Citizen

ON Wednesday evening, March 26, the New York Sections of the American Institute of Mining and Metallurgical Engineers, American Society of Mechanical Engineers and Society of Automotive Engineers held a meeting at which was presented an engineers' symposium on "The Engineer as a Citizen." Local members of the electrical engineers, civil engineers and thirteen other engineering and technical societies were invited to participate.

In opening the meeting the presiding officer, MR. GANO DUNN, called attention to the fact that engineers were earnestly examining themselves and their organizations to determine what their relation should be to society. He felt that we should not be led astray into a zeal for doing things for society in general which we would not do first for our fellow engineers, and that the man is inconsistent who urges something for society which he is unwilling to do for his fellow engineer.

Civic Responsibility of the Engineer

The first speaker was MR. PHILIP N. MOORE, representing the American Institute of Mining and Metallurgical Engineers, who spoke on the civic responsibility of the engineer. Mr. Moore saw the engineer waking from a long sleep of indifference to a sudden realization of the fact that he was not politically potent. Examining the reasons for this failure of the engineer to count as a class politically, Mr. Moore found the following reasons: First, a lack of local attachment. Engineers are constantly working themselves out of a job and have little time or inclination to take an interest in local affairs. Being without local responsibilities they have a small sense of civic duty. Again the relation of the large proportion of our engineers to the great business consolidations, many of which have in the past been antagonistic to the interests of society, leads them to withhold from civic activities. Furthermore, the training of the engineer is too often merely technical and fails to give him an interest in the welfare of the community of which he is a part. The remedy for the isolation of the engineer lies within himself, and he must realize that it is his duty as well as his privilege to participate in civic affairs. Mr. Moore felt that the engineer's voice would be a potent factor in bringing the world to a realization of some elemental truths, namely, that the hand deserves not the same reward as the brain; that there is no justice in the demand of the worker to share profits unless he is also willing to share losses, and that there is no partnership where gains alone and not risks are shared; that no wages are earned which are not fully reproduced in product; that labor can be paid only from the product of its toil when that product is sold at a profit; that all products are the result of the joint effort of labor, capital and management, and that all of these must share the output.

Relation of the Engineer to Legislation

MR. CALVERT TOWNLEY, representing the American Institute of Electrical Engineers, spoke on the relation of the engineer to legislation. He reviewed briefly the efforts which engineering societies had made in recent years to influence or bring about legislation on engineering matters and showed that the policy generally had been to confine the activities of engineers to a statement of the facts and to refrain from expressing views as to the wording of any legislation or opinions on legal matters. The speaker was of the opinion that this is about as far as engineers can go because, while they will be found in close accord on fundamental engineering questions, they cannot be expected to agree on general legislation any more than any other body of educated men. He spoke of the efforts of Engineering Council to keep in touch with legislation through the National Service Committee with an office in Washington, D. C. In conclusion it was the speaker's opinion that we should not try to influence legislation which concerns us only as citizens, but that if we undertake the task at all we should concentrate on certain specific lines of engineering importance.

The relation of the engineer to administration was discussed by MR. NELSON P. LEWIS, representing the American Society of Civil Engineers. The speaker found that engineers were assuming a more important

place in the administration of large industrial enterprises, but that they have been more completely excluded from the public administration of the affairs of cities and States. Mr. Lewis asked, however, "What is the city or State but a public service corporation?" He felt that engineers should play a conspicuous part in the administration of city and State affairs. He showed how the commission government plan grew out of the Galveston disaster, and the commission-manager plan out of Dayton's experience in 1913. He felt that the engineer with executive capacity was especially well qualified to fill the position of commission-manager in city administration. At the beginning of 1919, 124 cities and towns in the United States were operating under some form of the city-manager plan, and out of 88 of these managers 50 were professional engineers, 9 merchants, 6 minor city officials, 5 general business, 3 superintendents of construction, 2 journalists and 13 miscellaneous. In conclusion the speaker felt that the trained engineer is the logical man to manage undertakings involving the planning and execution of engineering work, and that the educational preparation for such work should include a knowledge of business and administrative methods as well as a knowledge of purely technical subjects.

The Engineer and Public Opinion

Mr. Spencer Miller, representing the American Society of Mechanical Engineers, spoke on the relation of the engineer to public opinion. The speaker believed that "public opinion is not always right, but it is always autocratic." He felt that the importance of the engineer in public life was such that we should make every effort individually and collectively to mold public opinion in the right direction and especially to counteract the propaganda which tends to stir up class hatred. Many of the engineers who occupied positions of responsibility during the war will be invited to accept still larger responsibilities as public servants, and they have an opportunity to mold public opinion along the lines of honesty, integrity, unselfishness, self-control and co-operation. These qualities make the engineer successful in public life. The speaker was of the opinion that a Congress half lawyer and half engineer would be superior to one all lawyer or all engineer. Both types are needed in public and political life. The speaker felt that a good beginning toward molding public opinion would be the adoption of a code of ethics which should become the moral foundation of all engineering associations.

Production and Distribution

Dr. C. A. Adams, president of the American Institute of Electrical Engineers, closed the symposium with a discussion of the relation of the engineer to production and distribution. He departed from his subject in the beginning to say that his long experience with engineering education had convinced him that it is not the curriculum and the subjects taught that count in the making of an engineer, but that the way in which they are taught is the important matter. He believed that one could "put more spirit and more character building and more general preparation for citizenship into a course in dynamo design" than could ordinarily be found in courses in economics, history or government. The speaker then referred to the industrial situation in the world today and the part which the engineer could play in effecting a settlement between contending forces. The machinery of production and distribution is largely in engineers' hands and he thought that it could be so improved as to increase the productivity of labor and thus make possible a living wage and a fair return for capital. He felt that our present competitive methods are wasteful in the extreme, and add to the cost of production and distribution.

There was considerable discussion of the subject, with particular reference to ways in which the engineer could function in public affairs through his societies. Mr. S. N. Castle suggested that there were four methods: The merger of existing societies into one large national organization; a New York engineering society or metropolitan association of engineers to comprise the New York sections of the national societies; an association of the delegates or officers of the New York sections of the national societies; or finally, interlocking committees in the national societies. Mr. Daniel Turner felt that there was no need of organizing a new society, but that the American Association of Engineers could serve the purpose of uniting all engineers in matters relating to public affairs. Mr. J. E. Johnson, Jr., thought that Engineering Council could serve engineers better if it were more national in its scope. It was his opinion that this organization was suffering from distinguished men who had made their reputations and who hesitated to take any serious or radical steps for fear of losing what they had gained.

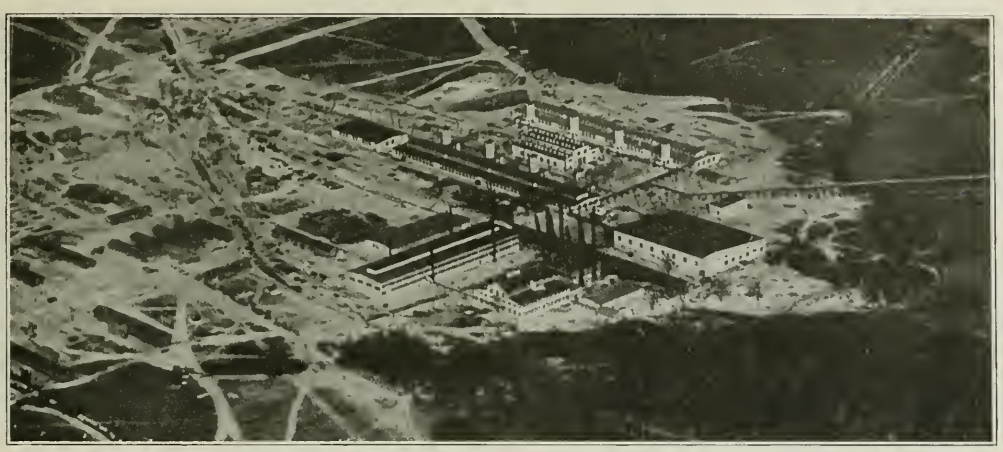
Joint Conference for Closer Co-operation

A resolution was adopted asking the various societies represented, or their local sections, to appoint delegates to attend a joint conference with a view to organizing for closer co-operation between engineers in the metropolitan district. Another resolution called upon all engineering societies of this country which have not yet appointed committees on development, to appoint such committees with instructions to undertake a survey of the aims and purposes of their respective organizations and to co-operate with similar committees of engineering societies. A third resolution called for the appointment of delegates from the societies repesented in the meeting to a conference for the purpose of discussing and formulating a proposed code of ethics for the professional conduct of engineers.

Manufacture of Phthalic Anhydride

On June 16, 1917, the Department of Agriculture announced that the Color Laboratory of the Bureau of Chemistry had developed, on a laboratory scale, a new process for the manufacture of phthalic anhydride and was ready to co-operate with manufacturers in the attempt to develop the process on a commercial scale. All of the co-operation that could be handled at that time was obtained and on Nov. 1, 1917, the offer of co-operation was withdrawn.

Inasmuch as a number of manufacturers recently have expressed a desire to produce phthalic anhydride and co-operate in the experimental work, the Department of Agriculture announces that it is ready to assist manufacturers by reopening this offer of co-operation on the same terms and under the same form of agreement as originally made with other manufacturers. This offer of additional co-operation is made possible by the release from war work of men of the Color Laboratory. It will not be held open indefinitely.



AEROPLANE VIEW ELECTROLYTIC CHLORINE PLANT, EDGEWOOD ARSENAL

New York Meeting of the American Electrochemical Society

First Post-War Meeting Marked by Symposium on Released Information Showing Part Played by Electrochemistry in the War—Election of Officers and Transaction of General Business—Excellent Financial Condition of the Society

THE thirty-fifth general meeting of the American Electrochemical Society convened at the Chemists' Club in New York City, April 3, 4 and 5. Being the first post-war meeting of the Society, there was a large attendance and ample evidence of removal of that sober restraint which the business of war had exercised over the activities of the members. Thus Section Q and its familiar pastimes were revived at a smoker with the usual success; and a trip of inspection scheduled for Saturday morning was well attended in spite of inclement weather.

Meeting of the Directors

The Directors met for the transaction of annual business and considered some important matters. The sum of $2000 was set aside for investment in the forthcoming Victory Loan, following the precedent established for previous Liberty Loans. This will make a total of $10,000 invested in Government bonds. The general financial condition was shown to be unusually good. Liquid assets aggregate $20,000, or $10 per member. Additional assets in the form of publications, which are being sold at the rate of about $2000 per annum, amount to another $20,000, or a total of about $20 per member. The membership committee reported a membership of 1928.

At the invitation of Engineering Council the directors appointed Mr. F. A. Lidbury to represent the Electrochemical Society at a meeting of the National Service Committee of the Council, to be held in Chicago April 23-25, for the purpose of promoting the establishment of a Department of Public Works in the Federal Government. Mr. Lidbury was instructed to support the movement.

A committee, not yet named, is to be appointed to co-operate with the American Society for Testing Materials on standard lime specifications.

Messrs. Cottrell and Dwight were appointed to represent the Society at a conference in Paris called to consider an inter-Allied federation of industrial chemical societies.

A resolution was adopted approving proposed legislation by the next Congress appropriating $50,000 for a water-power survey of the country by the Geological Survey, and $200,000 for a survey by the Geological Survey and the Bureau of Mines of the various sources of power in the industrial region of the North Atlantic seaboard.

Officers Elected at Annual Business Meeting

The committee on patent legislation was represented by Mr. E. J. Prindle, who presented a digest of the report prepared by the patent committee of National Research Council, with the recommendation that the Electrochemical Society approve it. This report has already been published in Chemical & Metallurgical Engineering, Feb. 15. It was approved by the Society.

The recent annual election of officers for 1919-20 resulted as follows: President, Wilder D. Bancroft; vice-presidents, J. V. N. Dorr, W. R. Whitney, Carl Hering; managers, H. C. Parmelee, R. E. Zimmerman, E. Blough; treasurer, P. G. Salom; secretary, J. W. Richards.

Oppose Government Ownership and Operation of Water Powers

The Committee on Public Relations presented a report condemning Government ownership and operation of water powers. This report met with some opposition

on account of its partisan nature, the opponents of its adoption not necessarily opposing its provisions, but feeling that it would have even more force if it was more judicial in tone and not a bit of special pleading. In spite of opposition, however, the report was adopted as follows:

"It is understood that this report does not consider the question of the Government ownership of sources of hydro-electric energy nor of Government control and regulation of hydro-electric systems; but simply operation by the Government of hydro-electric systems in comparison with operation thereof by private companies. As regards this aspect of Government ownership it is the opinion of your committee:

1. That anything which affects, either for good or evil, electrochemical industries will effect in a corresponding way the people as a whole.
2. That the inherent defects of governmental activities in industrial enterprises will be found in Government ownership of hydro-electric systems and will affect the electrochemical industries dependent on such systems adversely.
3. That the American Electrochemical Society, being interested in and representing the electrochemical industries of the United States, should strongly oppose all attempts at governmental operation of hydro-electric systems.

"It is needless to present any evidence to the members of the American Electrochemical Society that the electrochemical industries are of vast importance to the whole nation and to every individual composing it.

Even a superficial examination of numerous governmental activities shows that those which can only be undertaken by the Government leave much to be desired in their results and that when these are of an industrial nature they are invariably inefficient, uneconomical and subject to numerous glaring defects which are obviously inherent in governmental work of this kind in a democracy, when the present state of human character is considered. Under an autocratic government certain causes of the defects of such governmental activities do not exist; but, as recent experience has shown, even when the existence of a democratic nation is threatened by external aggression and a temporary reversion to autocratic government becomes necessary, governmental industrial enterprise is far inferior to private undertakings of this nature.

"It is the belief of all American citizens that governments are instituted among men to secure certain inalienable rights, among which not the least is individual liberty, and that the reason why their country has prospered so wonderfully is because those intrusted with its administration have not only confined themselves within their constitutional spheres, but have refrained from encroaching on and consequently diminishing the fields of activity of its citizens. Most of our citizens who have given the matter careful thought also believe that governmental encroachment in such fields will greatly overbalance, in permanent evil, any partial or transient benefit which it may yield.

"There is no evidence that governmental ownership of hydro-electric systems will be any freer from defects than other kinds of governmental industrial enterprise, but quite the contrary.

"Your committee believes that the American Electrochemical Society should have an opportunity to go on record as opposed to Government ownership and operation of hydro-electric systems and that this record should be given the widest publicity."

The Smoker and Inspection Trip

The smoker, under the direction of Mr. M. B. Coho, proved to be a great success. As a parody on the afternoon's program on released information, Mr. Ellwood Hendrick read a paper on Deceased Information, in which he brought forward a few delicious bits of scientific information promulgated by Pliny the Elder, who perished in the eruption of Vesuvius, 79 A.D. This was followed by an exhibit of unusual views of some members of the Society, thrown on the screen and "explained" by Mr. L. E. Saunders. The program was concluded by a view of several animated mechanical movies, by courtesy of the Bray Studios. These included demonstration of the mechanism and operation of the Lewis machine gun, the internal combustion engine and the telephone. Singing and a Dutch lunch concluded the plans for the evening.

The inspection trip Saturday morning was attended by over 100. Visits were made to the Loose-Wiles Co., the Wright-Martin Aircraft Co., and the Nichols Copper Co. Luncheon was served at the latter place by courtesy of the company.

Presidential Address and Technical Papers

The opening address was that of President Tone on "Electrochemistry in Its Human Relations," which is printed in full elsewhere in this issue.

Principles of Inductive Heating With High Frequency Currents

DR. E. F. NORTHRUP, who has recently perfected a new type of electrodeless electric furnace at the Palmer Physical Laboratory at Princeton for the Ajax Metal Co., gave the theoretical principles involved in inductive heating. He derived equations whereby rates of heating and thermal efficiencies can be obtained in quaternary circuits with e.m.f. impressed on the primary circuit, also general equations applied to a single pair of coupled circuits. In conclusion Dr. Northrup said:

"The development of electric heating with high-frequency currents and without interlinkage of an iron magnetic circuit with an electric circuit was brought by the writer to its present stage of development (December, 1918) almost entirely by laboratory experimentation. In the course of this experimental work it has been proved beyond doubt that, using oscillatory currents to secure the requisite frequency, rapid heating of a crucible and its contents may be obtained with a thermal efficiency in the neighborhood of 60 per cent, and temperatures up to 1800 deg. C. or 2000 deg. C. may be obtained. Batches of several kilograms of such materials as Pyrex glass among the non-conductors and pure iron and pure nickel among the conductors have been rapidly melted in air and in vacuum. Platinum has recently been melted without the presence of carbon in a 20-kw. furnace sold to the Baker Platinum Co.

Nature of Problems Recognized

"After these experimental results had shown the correctness of the physical ideas which led to and guided the experimental developments, the precise nature of the problems involved became more and more clearly recognized. The necessity became apparent for developing in a comprehensive way a complete theory of this method of electric heating, and of other entirely new engineering matters which develop when high-frequency currents, in connection with large amounts of power, are utilized.

"These theoretical foundations have now been laid and all the basic mathematical relations have been found which are necessary for, and will permit the design of, very large power heating units.

"For electric furnaces which require the use of 100, 500, 1000 kw. or more, it is highly probable that the best and most practical source of the high-frequency current required is, in the light of present practice, an electric generator direct connected to a steam turbine.

Voltages Required

"Practical considerations demand that the voltages applied to, and used near, the heater unit shall be well below any voltage which might be dangerous to life. The mathematical treatment proves that there is no theoretical limitation in this method of heating, either to the voltages which may be safely used or to the size of the units and the amount of power which may be employed. Theory also shows that in all cases where the high-frequency current is obtained from an alternator the supply lines can furnish power at practically unity power factor and that the possibilities of obtaining high thermal efficiencies and rapid heating and elevated temperatures are equal to or better than the results obtained in these respects by standard methods of electric heating. Futhermore, both theory and experiments have proved that uniformity in the temperature of the heated mass, perfection in the control of temperature and the ability to heat up charges from the cold with great rapidity exceed anything heretofore obtained in electric furnace practice.

Path Now Laid for Advance

"The path is now laid and the mathematical formulæ are given for the purely engineering advance in the designing of large power units for heat treatment of materials (glass, non-ferrous and ferrous metals) in tonnage quantities.

"The oscillatory current system for obtaining the required current of high frequency has not so far been utilized in power units exceeding 60 kw. The large expense of the condensers required, which are only active in the oscillatory current method from one-fifth to one-sixth of the time, the rather low power factor connected with this system and the high voltages required for generating the oscillations would seem to limit this method of obtaining high-frequency current to single power units of the order of magnitude of 100 kw.

"Two or more oscillatory current systems may be made, however, to operate in conjunction to heat a single furnace of large dimensions.

"Because, on the other hand, high-frequency currents may be obtained with oscillatory discharge with ap-

paratus which contains no moving parts and which has an exceedingly slow depreciation, this system of heating is ideally adapted to small power installations and to all kinds of laboratory furnace practice.

Larger Problem Awaits Solution

"The much larger problem, of the heat treatment of materials in tonnage lots, awaits for its practical solution the development of less expensive and more efficient means of obtaining currents of 10,000 cycles or more in limitless amounts. Intensive investigation is now in progress in several quarters looking to the development of high-power, high-frequency apparatus, and full success in this matter will mean a great and highly satisfactory solution of the future commercial heat treatment of materials in large quantity by means of the electric furnace."

Extraction of Uranium From Pitchblende

The carbide method of separation as developed by Gustave Gin and communicated to the society prior to his death was given in connection with the methods used at Joachimsthal.

The powdered mineral is roasted in a reverberatory furnace until sulphur is all removed. Almost all the arsenic is likewise removed and the uranium changed into sesquioxide.

The roasted material is mixed with carbon and put into an electric furnace with two hearths. The quantity of carbon introduced should be insufficient to reduce all the metallic oxides. The lead, copper, iron, nickel, cobalt, and perhaps a little of the tungsten, will be liberated as metals, and there is formed a slag containing silica and the lower oxides of uranium, vanadium, tungsten and molybdenum. The base metals are run off and carbon is then added to the slag in sufficient quantity to reduce the oxides and transform them into carbides.

The further treatment in the electric furnace gives a mass of carbides of uranium, tungsten, vanadium and molybdenum, which if cooled quickly on removal from the furnace can be easily pulverized. The powdered carbides are treated with water at 60 deg. C. Uranium carbide decomposes water, giving hydrated uranium oxide, green at first, but rapidly becoming blackish on contact with air. This precipitate is separated by flotation and dried and calcined. It then serves for the electric preparation of the pure metal or of its alloys or for the manufacture of uranium compounds such as the nitrate of alkaline salts.

Treatment of Residue

The residue from the treatment with water contains all the unattackable carbides and silicides. It is dried and treated with potassium nitrate to fusion resulting in a mixture of the alkaline vanadates, tungstates, molybdates and silicates. This fusion is dissolved in hot water and hydrochloric acid added. Tungstic and silicic acids are precipitated while molybdenum and vanadium remain in solution with any phosphoric acid. After filtration and washing of the precipitate tungstic acid is separated from the silica by fusion with bisulphate of potassium. The product of this fusion is dissolved in water, which removes potassium sulphate and leaves a white residue of tungstic acid and silico-tungstate of potassium. The residue is treated with cold water to which is added ammonium carbonate, dissolving the tungstic acid and leaving the silico-tungstate undissolved.

In the solution coming from the first operation and containing molybdenum and vanadium it is extremely difficult to remove phosphoric acid, and it is preferable in practice to precipitate it as ammonium phosphomolybdate. The solution is concentrated and ammonia is added until a yellow precipitate is no longer formed. Filter, and in the filtrate the vanadium present may be precipitated as ammonium vanadate by adding ammonium carbonate and crystals of ammonium chloride. The filtered liquid contains only ammonium molybdate, that is if all the molybdenum has not previously passed into the phospho-molybdate. The ammonium molybdate is obtained by concentrating to dryness and calcined in the air to molybdic acid.

Finally, molybdic acid may be separated from the phospho-molybdate by dissolving it in a concentrated ammoniacal solution and adding chloride of magnesium to precipitate the phosphoric acid as ammonium-magnesium phosphate.

Dr. S. C. Lind, Bureau of Mines, Golden, Colo., contributed a discussion in which he called attention to the radical change which had occurred in the last ten years regarding the rare elements. Pitchblende, formerly the chief ore of uranium, has been relegated to secondary importance by the carnotite of Colorado and Utah. Furthermore, uranium, formerly the principal product of the treatment of pitchblende, is now almost a by-product, with radium of primary importance. This has altered the metallurgical processes, and has brought into prominence that using an initial nitric acid leach as opposed to the older methods using sulphuric acid which throws radium into the tailings as a sulphate.

Electrolytic Silver and Gold Refining

Mr. George G. Griswold gave the following account of the Moebius process: "The first electrolytic plant for the treatment of doré bullion was put in at the Kansas City Smelting & Refining Co., Argentine, Kansas, in 1884 or 1885 by Dr. Moebius. This worked entirely satisfactorily, and was followed by other installations. The second was at the Perth Amboy plant of the American Smelting & Refining Co. These were of the Moebius vertical type. Dr. Moebius afterward patented a horizontal system with traveling silver belts for cathodes, a small installation of which was made at Perth Amboy, but did not prove as satisfactory there as the vertical type. When the parting plant was destroyed by fire, in 1897, it was decided to install the vertical system in the new plant. The decision to adopt this system was due to its greater capacity for a given floor space, smaller tie-up, and the fact that being run in connection with a lead refinery the anodes could be cheaply made 990 fine or better.

"The new tank room contains twenty-four sections of six tanks each, the sections being in series and the tanks in multiple. In the original installation the tanks were made of wood, which was never very satisfactory, and consequently stoneware tanks were used in the new plant.

The Anodes and Cathodes

"The anodes, weighing about 100 ounces, are cast by hand in the lead refinery and transferred in locked steel boxes, by a storage battery truck, to the parting plant. They are weighed, counted and punched, and are then used as required. The punching gives a slight depression on each side of the ear of the anode, thus furnishing a secure hold and better contact for the spring clips

which support them. The cathodes were made from cold-rolled silver sheets $\frac{1}{32}$ in. thick. There are 4 bags and 5 cathodes in each tank, and each bag holds 4 new anodes. Seventy-five per cent of the silver is deposited in 24 hours. It is constantly brushed from the cathodes by wooden sticks, rigidly attached to a wooden frame having a reciprocating motion, which serves to prevent short circuiting and also to give circulation. The deposited silver falls into wooden silver boxes, and is removed daily by dropping the hinged bottom of the silver boxes, which dumps the silver into a tray from which it is emptied into a wooden silver-car, provided with a false bottom and filter. The car is transferred to vacuum boxes, the silver washed, and then transferred to the melting room, where it is dried, melted, and cast into bars.

"The electrolyte is a neutral nitrate solution containing 15 to 20 grams silver and 30 to 40 grams copper per liter. Silver nitrate is added as required, and enough electrolyte withdrawn daily to keep the purity up to standard. The waste electrolyte is put in a wooden tank and the silver precipitated on copper, after which the copper is cemented out on iron and the resultant solution, after passing over lime, thrown away.

Current

"Current was supplied by an engine-driven generator in the same building and a current density of 19½ amp. per sq.ft. carefully maintained; but later it was found more advantageous to install a motor-generator set in the central power plant, and to increase the current density to 40 amp. per sq.ft., which increased the capacity accordingly. The current is carried from the switchboard by copper cables which distribute it through mercury-filled copper cups over ⅞ in. cold-rolled copper bus-bars, the end ones being bent to fit into the mercury cup when lowered into position.

"The bags which contain the gold slime are removed at regular intervals, and the contents sluiced into the gold box, thoroughly washed, transferred to iron boiling kettles, and treated with H_2SO_4, 66 deg. B., to remove the copper and silver. The gold slime is washed, dried and cast into anodes for electrolytic refining by the Wohlwill process. The liquor from boiling the slimes is run into lead-lined tanks, and the silver precipitated out on copper. The copper-bearing solution then goes to the copper refinery.

"The Wohlwill installation has five cells, and is in series with the silver sections. At the time it was put in, owing to the war, it was not possible to obtain porcelain, and stoneware cells were used. With the high current density of 150 amp. per sq.ft. osmosis develops in the stoneware; also, as they crack with any unequal strain, it was necessary to place them in a lead-lined box filled with water heated by steam coils. The boxes are supported in a lead-covered table with cupped top.

"An interesting feature is the use of mercury cups on the ends of the copper bus-bars, whereby any unit or units can be cut in or out quickly by using cross bars, also of copper. with ends bent to fit into the cups.

"The cathodes are thin gold sheets, rolled from electrolytic gold, and are connected to the contact bars by bending one end of the sheet around them and clipping them fast.

"The electrolyte contains 30 per cent free HCl, 80 to 85 g. gold per liter, and varying amounts of platinum and palladium. When the solution accumulates a sufficient percentage of these latter metals, a portion is withdrawn, and they are separated, refined and sold as pure metals."

Process for Refining Nickel

Mr. George A. Guess gave a description of a new method in which impure nickel, containing copper and iron, is electrolytically refined, using it as anode. Iron goes into solution and accumulates there, but copper, which also goes into solution, is precipitated therefrom continuously by keeping powdered calcium carbonate (limestone) suspended in the electrolyte. An unusual salt is thus formed from the copper in solution, $2CuO.2NiO.SO_3$, completely precipitating out copper, which settles, with $CaSO_4$, as a mud. The cathode is enclosed in a canvas bag to keep it free from mechanical impurities. Glue is used in the solution. The cathode nickel contains usually less than 0.001 per cent copper. The mud is reduced by fusion to a nickel-copper matte, which is dead roasted, and then reduced to nickel-copper alloy, NiCu, which is used as anode in an ordinary copper refining bath to recover its nickel as sulphate.

Referring to Mr. Guess' paper, Dr. Hering pointed out that in this case we have a suspension of solid particles in an electrolyte, and that they would migrate in a definite direction, usually with the current to the cathode. For this reason he thought it would be necessary to put a porous cell around the cathode to prevent the deposition of these solid particles, and he wondered whether the arrangement provided by the author would be effective. Mr. Hogaboom called attention to the use of glue in the electrolyte and said that his own experience was that glue produced dark and brittle deposits of nickel. He questioned the advantage of its use.

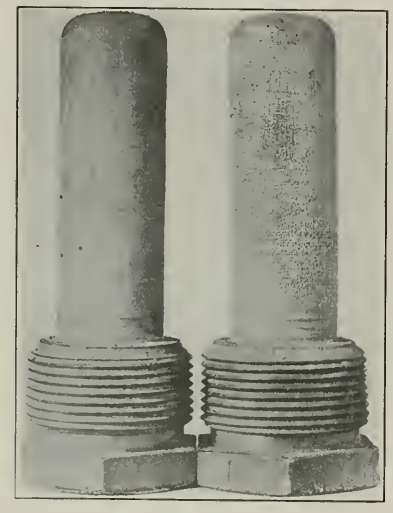
Electroplating

Mr. Oliver P. Watts reviewed his investigations on electrop'atings of copper upon iron by preliminary dipping of the iron article in solutions of various metals which lie, electrochemically, between iron and copper. Arsenic, antimony, bismuth, lead and tin dipping solutions were tried, and arsenic, lead and antimony solutions found effective in securing a good subsequent electroplating of copper. Even bismuth can be electrodeposited on iron by using a preliminary arsenic or antimony dip. Nickel can be deposited on aluminium by using a ferric chloride dipping solution. The paper will be published in a future issue.

In discussion one member related his experience with nickel-plated steel surgical tools. The plate peeled from these articles, particularly at or near the cutting edges. On careful examination it was found that there was a film of dirt on the steel wherever the nickel peeled, and investigation was made to ascertain how the dirt got there. It was believed that the dirt came from particles floating on the surface of the solution which would adhere to the steel articles when they were placed in the bath. It was also thought that these particles being submerged might be carried by the current and deposited on the articles. A preliminary copper plating was considered advisable in order to make the nickel more adherent.

Mr. Hogaboom was of the opinion that a dirt film on the surface of the bath would affect the articles regardless of a preliminary copper plate; and Mr. Reeve

doubted if the dirt came from floating particles because it had been his observation that when articles were placed in the plating bath the surface film spread when touched and thus left a clean surface through which to insert the articles into the bath. He was of the opinion that the surface of steel was such that while it might appear to be clean, it would still have pin-holes containing dirt which would prevent good plating. He said that the "water-break" test is not adequate to determine the cleanliness of a steel surface. MR. MADSEN questioned the value of a preliminary copper plate in order to make the nickel adherent. He thought that floating dirt on the bath which might become wetted and sink would migrate with the current and be deposited in the plate. He thought also that impurities in the anodes



PITTING IN ELECTROPLATING

might act likewise, and that under certain conditions of current, temperature, etc., nickel oxide might be carried across. DR. RICHARDS thought that the whole trouble of peeling on sharp-edged tools would be avoided by making them of the alloy stellite.[1]

When making some lead platings, Mr. Watts observed that heavy pitting suddenly and irregularly appeared. After considerable study of the cause, it was finally found to be due to air dissolving in the electrolyte while it was resting over night and cooling, which was then expelled as minute air bubbles on the work when the bath was heated up by the passage of the current. The microscopic bubbles clinging to the work, which had been left immersed in the bath, started the pitting.

The difficulty was overcome by heating the solution to a little above its working temperature by means of a lead steam coil before resuming plating, whenever the tanks had been out of use for any considerable time.

MR. HOGABOOM reviewed his experiences with pitting in electroplating and exhibited a piece of silver plating on glassware which he had made many years ago. Various experiences and experiments confirmed him in the belief that the pitting was due to air in the solutions, particularly the surface layer of the solution in the vat. He thought that lead deposits were affected more than other metals by air in the plating solution.

[1]See this journal, May 15, 1918, p. 541.

Notes on Electrostatic Precipitation

MR. H. D. BRALEY reveiwed electrostatic separation of particles from gases and emulsions. The various applications discussed are: Recovery of metallic dust, of antimony, sulphur and arsenic, of potash, of sulphuric acid fumes and the dehydration of aqueous oil emulsions. Accounting data obtained from the International Smelting Co. show that the process has unquestionable financial merits. Separate discussions are given regarding the construction and operation of various types of treaters, temperature control as affecting operation, gas velocity during treatment, direction of gas flow, capacity of electrical supply, operating voltage, apparatus, transformers, generators, synchronous motors, rectifiers and accessories.

In discussion of this paper DR. DUSHMAN expressed the belief that the kenotron was more practical in current rectification than indicated by Mr. Braley. The operating temperature of the filament is about that of the ordinary incandescent lamp—far below the melting point of tungsten. He stated that the research laboratory of the General Electric Co. had perfected a control panel which protected the kenotrons against high-voltage stresses. The basic difference between the kenotron and the mercury-arc rectifier is that the former can be operated in parallel to get any quantity of power, which is not possible with the mercury-arc. Further, the kenotron can be operated up to 150,000 volts, and reduces to a minimum the surging in the precipitator circuit. He showed oscillograms of kenotron operation in comparison with mechanical rectifier operation, taken in co-operation with the Research Corporation. These portrayed the peculiar characteristics of the circuit of the Cottrell precipitator, one feature being the flattening effect produced on a high voltage wave due to the corona load. Others showed the smooth waves, both current and voltage, with kenotron operation, as compared with unsteady current conditions and distorted voltage wave with the mechanical rectifier.

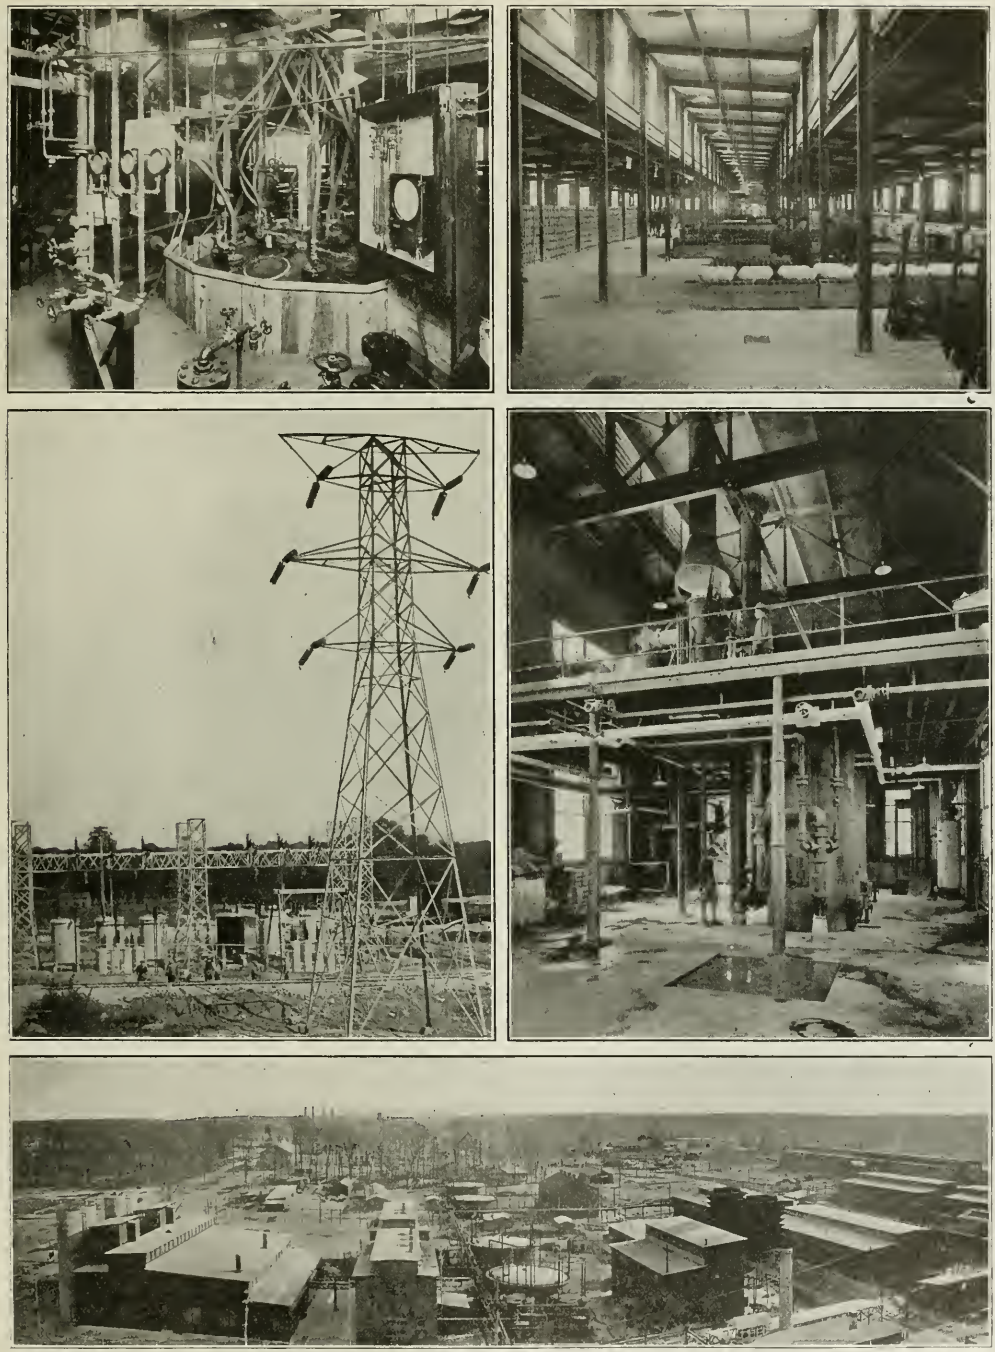
Nelson Chlorine Cell

MR. C. F. CARRIER of the American Cyanamid Co. gave the history and a description of the construction and operation of the Nelson cell. Because of the important part this cell has taken in chlorine production, the full paper will be presented in an early issue.

The illustrated lecture on oxidation of ammonia to nitric acid, by MR. W. S. LANDIS, was largely attended. The paper will be printed in full in a subsequent issue.

Symposium on Released Information

No body of scientists and engineers played a more important part in preparation for war than did the electrochemists. To their lot fell a vast amount of research, construction of tremendous plants and production of important munitions of war. Some of their achievements were disclosed for the first time in the symposium which the Society held on April 4. As one listened to the successive speakers, almost all of whom explained that their work had been interrupted by the armistice, one came to the conclusion that the said armistice was a great bar to scientific progress as well as to the defeat of Germany.



VIEWS OF EDGEWOOD ARSENAL

Upper left—Levinstein mustard gas reactor. Upper right—Shell storage. Center left—Transmission line and transformer station. Center right—CO gas producer. Bottom—General view of phosgene plant.

Col. W. H. Walker gave an illustrated lecture on Edgewood Arsenal, which was a development of the Chemical Warfare Service constructed for the manufacture of poison gases and the filling of shells. He made some introductory remarks on the nature of gas warfare, along the lines set forth in our recently published interview[2] with Brigadier General Amos A. Fries, to wit, that it was not wholly to be condemned and that it had some commendable features. Colonel Walker also expressed the hope that the Chemical Warfare Service would be re-established and maintained as a separate and distinct branch of the military forces.

In the early days of our preparation for gas warfare it was expected that the toxic materials for shell filling would be supplied by manufacturers, but it soon became apparent that this would be inadequate and that a special plant would have to be built. Edgewood Arsenal was the result. Here the Government built and operated a plant of which the country may be proud, both as to technical efficiency and economy of construction. The gases produced by the service were phosgene, chlorpicrin and mustard gas, or dichlordiethylchloride. In the production of the latter our chemists developed a process of treating sulphur chloride with ethylene under proper conditions. This method was far superior to the chlorhydrin process used by the Germans. Colonel Walker spoke enthusiastically of the work of the first enlisted men who worked at the Arsenal, giving them credit for a large share in the general accomplishment. It was his opinion, also, that in no other munition plant was there gathered together so efficient and loyal a body of scientists and engineers.

Smoke Screens

Mr. Otis Hutchins gave an account of the experimental work done in the laboratory of the Carborundum Co. on the production of silicon tetrachloride. A charge of 80 lb. of silicon carbide was packed around a carbon resistor consuming a current of 15 kw. at 15 volts. When heated to the temperature of reaction, chlorine gas was conducted through the mass and silicon tetrachloride obtained by leading the gas through a water-cooled condenser. An average of 20 lb. of $SiCl_4$ was produced per hr. which was limited only by the available chlorine supply. The efficiency of the reaction was from 85 to 90 per cent. About 1500 lb. of $SiCl_4$ was made in all. Silicon tetrachloride was tested out comparatively with the other well-known chlorides of zinc, aluminium, phosphorus, etc., in organic synthesis, but was not found of any special applicability.

Silicon Chloride in the War

Major G. A. Richter gave an excellent account of the method of using silicon chloride in the war as follows:

"The funnel is a smoke device attached to the deck of a vessel and operated to produce a smoke screen as a protection against submarine attacks. It consists of a horizontal cylinder about 6 ft. long and 28 in. in diameter, provided with suitable connections for the introduction of silicon tetrachloride and ammonia under most advantageous conditions. One end of the cylinder is equipped with a hand fan, the function of which is to furnish large volumes of air for dilution of the respective vapors before mixing. The silicon tetrachloride is vaporized through a bank of very efficient spray nozzles located about 12 in. in front of the fan and directed toward the other end of the cylinder. The ammonia is introduced through another spray nozzle located about 12 in. from the exit end of the cylinder and also pointed toward this end of the apparatus.

"The ammonia is forced through the nozzle from a steel cylinder by means of its own vapor pressure. The silicon tetrachloride is propelled from a second steel cylinder by means of dissolved carbon dioxide. The tetrachloride line running from the cylinder to the nozzles is provided with a glass-wool strainer to remove any particles of sediment which may accumulate in the system on standing. To operate this smoke device, both valves leading from the tetrachloride and the ammonia reservoir are opened wide and the hand fan at the rear of the funnel revolved in order to provide sufficient air dilution of the vapors.

"Dry carbon dioxide was selected as a propellant for the silicon tetrachloride for several reasons. It does not react with the tetrachloride at any temperature likely to be encountered. The silicon tetrachloride is forced through the nozzles at nearly a constant pressure and rate, whereas with compressed air or nitrogen the rate of discharge of liquid is seriously affected by the progressive drop in the pressure within the container. Such a change in rate of discharge of silicon tetrachloride causes a variation in the proportion of chemicals delivered and consequently lowers the obscuring power of the smoke produced.

"When the pressure of a solution of carbon dioxide in silicon tetrachloride is released, it effervesces in a way similar to soda water. This behavior apparently causes an exploding effect on the particles of solution discharged through the nozzles, thus resulting in added disintegration and more rapid vaporization.

"Inasmuch as the vapor pressure of liquid ammonia and the total pressure of the silicon tetrachloride solution rise and fall with temperature changes, they tend to keep pace in rates of discharge through the nozzles. Experimentation established an optimum mixture of 12 per cent of carbon dioxide in the silicon tetrachloride. Under a surveillance temperature of 60 deg. C. this composition will generate a pressure of 600 lb. to the square inch. At —26 deg. C. this pressure drops to 225 lb. These experiments were conducted in a vessel two-thirds full of the liquid mixture.

"Every effort is made to duplicate as closely as possible in a practical way those conditions which proved most efficient in the laboratory. A ratio of two parts of tetrachloride to one of ammonia is maintained without much trouble. The liquids are sprayed through the funnel at a rate of 7 lb. and 3½ lb. per minute respectively. A heavy white cloud of high obscuring power is formed. It is easily set up, readily controlled and is so nearly neutral in composition as to allow the vessel generating the smoke to pass through it. A single pair of cylinders contains sufficient material to generate an efficient cloud for a period of thirty minutes."

A Portable Precipitator

Lt.-Col. Arthur B. Lamb gave the details of the miniature Cottrell portable precipitator which he and his research staff, Capts. Gerald L. W. Wendt and Robert E. Wilson, had developed. A lead storage battery in a special form offered the best supply of current so far as weight efficiency was concerned—30 watt-hr. at ½ amp. for 10 hrs. with a weight of 3 lb.

[2] See this journal, Feb. 15, 1919, p. 152.

The best induction coil was a special design furnished by the Samson Electric Co. of Canton, Mass., having an input of 5.8 volts with 0.46 amp., an output of 875 volts with 16 microamp., and an efficiency of 0.52 per cent. The weight of the coils were 14 ounces.

As many tubes as are necessary for the air volume required are used, connected in parallel. In its present form the precipitator uses four glass tubes 1½ cm. in diameter and about 12 cm. long, each wrapped in a strip of copper gauze. In a production form these glass tubes will presumably be replaced by thin tubes of iron or aluminium, glazed or enameled on their inner surface. The inner electrodes are made by cutting a strip of copper-wire cloth of fine mesh in such a way that only two adjacent parallel strands are included, together with the correspondingly short lengths of the many crosswise strands cut. This is then twisted lengthwise through four or five axial turns, and the ends of the long wires are inserted into the heavier electrode holders and insulated from the outer electrode tube.

The weight of the precipitator proper is less than a pound, and when manufactured in quantity need not exceed a few ounces.

EFFECT OF RATE OF FLOW ON PRECIPITATING EFFICIENCY OF SINGLE TUBE

Rate of Flow Liters per Minute	Efficiency Against NH_4Cl Smoke 1 in 10,000
3	100%
5	100%
10	93%
15	85%
25	79%

These results indicated that for a man exercising only moderately, four or perhaps five tubes should afford adequate protection against any toxic smoke. A full-size portable outfit was therefore roughly constructed and tested out in the main testing chamber by wearing it in a cloud of diphenylchlorarsine smoke set up by detonation. Such a test has been found to penetrate all except the very best filters within a few minutes, but the man wearing the electrical precipitator was able to remain for a full hour without suffering any discomfort whatever. This indicated conclusively that the smoke precipitation was complete under these conditions. There was no appreciable resistance to the flow of air through the precipitator. A canister containing gas-mask absorbent was, of course, used between the precipitator and the wearer in order to remove any toxic gas or vapors which might be present. It was found to kill bacteria suspended in the air drawn through it.

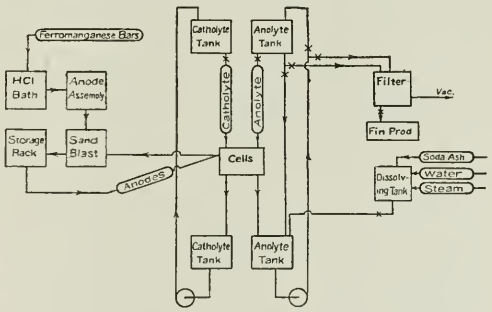
In discussion of Mr. Lamb's paper, MR. MESTON expressed the belief that it would be possible to get the same results with alternating as with direct current—with an induction coil as well as with a storage battery. DR. BANCROFT told of a small Cottrell precipitator which had been made for analyzing smokes, and MR. WILSON referred to the use of the apparatus in hospitals where it had been found much more efficient than the felt gauzes used in contagious diseases. DR. C. A. DOREMUS offered a note on the use of electrostatic precipitation in the manufacture of white arsenic from mispickel, or arsenopyrite. The ore was concentrated and roasted, and the fumes collected in a Cottrell precipitator.

Electrolytic Sodium Permanganate

MESSRS. ROBERT E. WILSON and W. GRENVILLE HORSCH reviewed the development of the ferromanganese electrode sodium permanganate process and gave the following account of the commercial half-ton plant:

"All things considered, the batch system of operation is the one best suited to the electrolytic production of sodium permanganate. Among the chief factors that lead to this conclusion are the simplification resulting from doing the cooling in one place outside of the cells, and the avoidance of the necessity for careful adjustment of the rate of circulation. Furthermore, uniformity of operation is gained by having all the cells throughout the plant operating on electrolyte of the same composition. With the batch system, the process will be intermittent with respect to the product turned out, but continuous in the sense that the current will be kept passing constantly through the cells, which will never be emptied of electrolyte except for purpose of cleaning and of renewal of the diaphragms.

"The interval of time selected for turning out of a single batch is one week. This interval is fixed by the amount of solution placed in the anolyte system and the final concentration of permanganate to be attained in the cells. One week is selected because if the interval is much greater the tankage required becomes excessive. On the other hand, if the interval is much less than one week the 'turn-over' becomes too frequent, resulting in increased labor requirements, and the condition is



FLOW SHEET

approached of having too small a volume of liquor to permit enough being outside the cells for adequate cooling and for settling out of the sludge.

"The concentration of sodium permanganate to be attained in the cells is limited to about 8 per cent, for the reasons previously pointed out. Fortunately, the evaporation of the solution may be carried out easily and inexpensively and if 30 per cent solution is to be produced, as was desired, it makes little difference in the final cost whether the evaporation is started from 8 or from 12 per cent.

"There are four principal operations to be carried out in this process; namely, the preparation of the solution, anode manipulation, filtration, and evaporation. When the plant is started for the first time an 18 per cent caustic soda solution has to be made up. During normal operation, however, there is only the simple preparation of a 12 to 14 per cent solution of soda ash.

"Anode manipulation is a question which demands more attention than it does in the majority of electrolytic processes. It is planned to have the cells arranged in banks of approximately eight each. It will then be possible to handle the anodes from all of the cells in one bank, simultaneously, using a small overhead crane. Thus, after shutting off the current from

the bank, eight anodes together will be raised, reversed, and lowered or carried to the sand-blast room to be cleaned, another set being put in their place. The sand-blasting can be effected while the anodes remain suspended from the trolley which conveyed them to the sand-blast room. The semi-plant scale experiments showed that the anodes would run more than twenty-four hours before needing reversing, and a slightly less time on the second side before removal altogether. It is therefore planned to make operations uniform by reversing the anodes in one-half of the plant each twenty-four hours, and to carry on replacement in the other half during the corresponding interval. This work would not, of course, consume the whole twenty-four hours, but could readily be carried out by two men during an eight-hour shift.

"In this process a sludge consisting of a mixture of the oxides of iron, manganese and silicon is always formed. It is planned to remove most of this by settling in the upper anolyte tank. For the purpose of washing the sludge and filtering the final product vacuum filters are installed.

"The power requirements and arrangement of circuits will be mentioned briefly. All the experiments which have been made are consistent with the belief that the energy consumption will be not greater than 12 kw.-hr. per lb. (26.5 kw.-hr. per kg.) of sodium permanganate produced. Allowing a loss of 3 per cent in evaporation, and, say, 10 per cent due to inactivity of a portion of the plant, a producing capacity in the cells of 1130 lb. (514 kg.) per 24 hr. must be allowed in order to turn out 1000 lb. (453 kg.) of the finished product. The power required is therefore found to be about 570 kw. It is planned to generate this power at about 112 volts. The cells will be connected in series-parallel, with a third wire running between in such a way that a single bank of eight cells may be cut out with very little disturbing effect on the current passing through the remaining cells. Running at a current density of 120 amp. per sq.ft., each cell exhibits a resultant drop in potential of about 7 volts.

"A design has been made and submitted to the Government giving rather detailed plans and specifications for a half-ton plant and including an estimate of the cost based on the best information in the light of all the work done. This estimate assumes the cost of raw materials, labor, and construction to be as they were in the year 1918, and provides for writing off the plant in two years.

"Based on these war-time conditions a fairly accurate cost of building and equipment (not including a substation, since the power cost estimate is based on 110-volt D. C., delivered to the plant) for such a plant is $85,000. Pure sodium permanganate in 30 per cent solution could be produced for about 60c. per lb. This cost can be further analyzed as follows:

Raw materials	$0.183
Power at $30 per hp.-yr	.067
Amortization	.120
Labor and overhead	.090
Contingencies	.140

Electric Furnace Manufacture of Silico-manganese

This paper dealt with war-time production of silico-manganese at Anniston, Ala., by the author, MR. B. G. KLUGH. The work was done in rectangular open-top furnaces comprising a steel shell 15 ft. by 7.5 ft. by 5 ft. high in one case, and 18 ft. by 9 ft. by 5 ft. high in another. The furnaces were 3-phase with 3 electrodes in line. Current was furnished at 22,000 volts and stepped down to 65 for the small and 100 for the large furnace. The raw materials used were silica rock, manganese ore, limestone and bituminous coal. The analysis of a 50-ton lot was Mn, 65 per cent; Si, 21; Fe, 13; C, less than 1. The following data relate to this product:

Ratio of ore to metal	3.53
Mn charged in metal, per cent	73.00
Mn charged in slag, per cent	10.02
Mn charged in gas (by diff.), per cent	16.98
Total weight of charge in metal, per cent	16.11
Total weight of charge in slag, per cent	31.34
Total weight of charge in gas, per cent	52.55
Pounds slag per ton of metal	4,358
Pounds gas per ton of metal	7,308
Pounds electrode per ton of metal	168
Pounds reducing carbon per ton of metal	1,715
Kw.-hr. per ton of metal	9,000

The author realizes that these results are not ideally economic, but presents them as showing what was accomplished under war-time conditions. In 1918, due to the shortage of manganese ores, the company made use of high-manganese slags from former operations, also from blast-furnace operations. One hundred tons of metal produced averaged Mn, 70 per cent; Fe, 9; Si, 20; C, less than 1. The treated slag and that resulting from the smelting had the following percentage compositions:

	Mn	SiO_2	Al_2O_3	CaO	MgO	BaO
Slag treated	20	34	14	25	2.0	1.5
Slag produced	1	29	23	42	2.7	1.6

Current consumption was 15,000 kw.-hr. per ton of metal. Mr. Klugh states that no difficulty is experienced in producing alloys of specified composition, within the limits of analytical error, and believes that if steel makers desired a certain SiMn alloy it could easily be furnished and replace the use of ferromanganese and ferrosilicon.

Lead Plating

MR. A. G. REEVE gave an interesting account of leading gas shells. Shells, copper "struck," filled with lead bath, anode and paddle, were placed on the plating bench (fifty-two 75 mm., 4.7 in. or 155 mm. shells per bench unit), anode and paddle quickly attached to the rotating spindles, and deposition begun.

Each spindle could be raised and disengaged from the driving pulley independently. The entire frame carrying the 52 spindles could be readily raised or lowered to suit the various shell sizes.

Current was supplied to the spindle through its two babbitt bearings set in woodwork. To use the available ampere-hours advantageously, the 52 spindles were divided into four batteries and connected in series, with 6-volt plating current, the 13 spindles of each battery being connected in multiple. To insure uniformity each shell was given a new anode, the old ones being re-cast.

The specification for gas shells required that the thickness of plating should not be less than ten nor more than fourteen thousandths inch (0.25-0.35 mm.) for all sizes, except that five thousandths (0.125 mm.) was desired on the threads in the opening. This was accomplished by withdrawing from the shell, when half plated, a small portion of the bath by use of a rubber bulb and a brass tube bent at the end so as to reach down only the required distance into the shell opening. To further equalize the thickness of deposit, each shell was turned part way around on its axis several times during the plating period.

The following table gives approximate data on the

volumes, areas, amperes, and time, etc., for three shell sizes:

	Exposed Anode Surface, Sq.In.	Cathode Surface Sq.In.	Ounces Lead Deposited	Amperes	Hours
75 mm.....	11.50 (18 sq.cm.)	64 (100 sq.cm.)	4.51 (127 g.)	5	6.63
4.7 inch.....	20.07 (31 sq.cm.)	147 (229 sq.cm.)	10.21 (289 g.)	10	7.50
155 mm.....	37.06 (58 sq.cm.)	266 (412 sq.cm.)	18.61 (529 g.)	20	6.84

The bath as received from the refiners ready for use analyzed about as follows:

Deg. Baumé	Per Cent Pb	Per Cent H_2SiF_6	Per Cent Free H_2SiF_6	Per Cent Glue
43	18.02	14.14	2.90	0.4

This was supposed to work best at 95 deg. to 100 deg. F. (35-38 deg. C.) with from 2 to 5 per cent free acid, and in practice it was found that the resistance of the bath was such that with 6 volts the shells and bath soon warmed up to the desired temperature while the plating was going on.

Regardless of the recommendations of those who furnished the lead bath, the quality of the deposit was materially improved by the addition of 2 lb. of glue to each barrel (50 gal.) (5 g. per liter) of new bath before using. As fast as the plating operation was completed the bath was poured out of the shells and filtered, and one lb. of glue added per barrel of bath (2.5 g. per liter) each time it plated a set-up of shells. The number of shells set up for plating with one barrel of bath and the volume of lead deposited per barrel set up, are given below:

	75 mm.	4.7 in.	155 mm.
No. of shells filled per barrel (190 liters) of bath...	346.0	100	42.37
Lb. of lead deposited per barrel (190 liters) of bath.	97.3 (44.2 kg.)	64 (29.1 kg.)	49.30 (22.4 kg.)

It will thus be noted that in the 75-mm. shells each gallon of bath deposited nearly 2 bbl. of lead in 6.63 hr., with one glue addition. The discoloration which the exterior of the shells acquired was scoured off by a revolving brush with an abrasive and water.

Mr. Blum called attention to the extension of lead plating, saying that before the war there were but two or three places in the United States where it was done, and that within two months after war was on there were from 20 to 25 plants in existence. He believed that lead plating was likely to find new applications in industry because there was no difficulty in depositing coatings up to $\frac{1}{16}$ in. in thickness. In lining some catalyzers for the Edgewood Arsenal the Bureau of Standards had treated an area of over 50 sq.ft. and had deposited 275 lb. of lead.

Mr. E. C. Walker said that he had eliminated the difficulty of plating the bottom of the booster orifice by circulating the electrolyte and using still anodes, whereas the author of the paper had used rotating anodes.

Mr. Frary referred to Mr. Blum's work at the Arsenal and said that before satisfactory work finally was done there had been trouble with blistering in the lead coating itself. It was finally proved that the trouble was in the preliminary pickling of the vessel, and that when the surface was prepared by sand-blasting instead of pickling the trouble vanished.

Mr. Bradley asked if the process could be applied to the lead-lining of pipes for resistance against attack of sulphuric acid. Mr. Reeve thought this could be accomplished without difficulty; and Mr. Walker mentioned the successful coating of pipes and buckets. The latter were used for carrying sulphuric acid, and had a coating 0.001 in. thick.

Mr. T. P. Baily gave a paper on the heat treatment of anchor chain, drawbar knuckles and aëroplane parts, and the melting of yellow brass, which was excellently illustrated with moving pictures. The heating is accomplished by an electrical resistor of granular carbon contained in carborundum fire-sand beds. The apparatus is controlled by pyrometers which maintain exactly the desired heats. Chains of 90 ft. length and 3400 lb. weight were treated at the National Malleable Castings Co. for the Emergency Fleet Corporation.

Mr. George K. Elliott described the experience of the Lunkenheimer Co. with duplex process iron castings. The molten iron tapped from the cupola was superheated in a basic electric resistance furnace. Improved fluidity was obtained due to the higher temperatures obtainable and, most important of all, the sulphur content was decreased from 0.1 per cent to 0.03 per cent in 25 minutes. The process presents an important field for future development where better strengths are required than can be obtained from ordinary cupola iron. Steel castings can readily be made, as there is no limitation to the heats obtained for fusions.

Mr. W. E. Moore discussed electric steel made in acid furnaces. He concluded that electric steel is superior to the product of the small ovenhearth or the converter in regard to costs of raw materials, alloys, refractories and composition control.

Mr. C. S. Cox of the Duquesne Light Co., Pittsburgh, read a paper on "Power Production for Electrochemical Purposes." He stated that steam-generated electricity can compete with hydraulic in all cases except where great natural advantages are found.

Resumption of Trade With Certain Countries

The War Trade Board has from time to time, since the armistice, announced the resumption of trade with certain countries in Europe with which trade was prohibited during the war by reason of the blockade.

In order that the business public may now have a complete list of these countries, the Board announces (W. T. B. R. 687) that trade has been resumed with Siberia (see W. T. B. R. 470, issued Jan. 3, 1919). Alsace-Lorraine (see W. T. B. R. 486, issued Jan. 8, 1919), Palestine and Syria (see W. T. B. R. 530, issued Jan. 20, 1919), Mesopotamia (see W. T. B. R. 560, issued Feb. 3, 1919), Servia and Roumania (see W. T. B. R. 551, issued Feb. 4, 1919), the territory included in the line set out in article 3 of the military clause of the armistice protocol of Nov. 3, 1918 (see W. T. B. R. 574, issued Feb. 4, 1919), Finland (see W. T. B. R. 590, issued Feb. 11, 1919), Czecho-Slovakia (see W. T. B. R. 594, issued Feb. 13, 1919), Bulgaria, Turkey, and Black Sea ports (see W. T. B. R. 602, issued Feb. 16, 1919, and W. T. B. R. 665, issued Mar. 24, 1919), German colonies (see W. T. B. R. 609, issued Feb. 21, 1919), the occupied territory of Germany (see W. T. B. R. 610, issued Feb. 22, 1919), Adriatic ports, Albania, and Montenegro (see W. T. B. R. 623, issued Feb. 28, 1919), Luxemburg (see W. T. B. R. 652, issued Mar. 17, 1919), the territory adjacent to and dependent upon the Adriatic ports, including Albania, Montenegro, Croatia, Slavonia, Bosnia, Herzegovina, and Dalmatia (see W. T. B. R. 656, issued Mar. 20, 1919), Poland (see W. T. B. R. 675, issued Apr. 1, 1919), Esthonia (see W. T. B. R. 676, issued Apr. 1, 1919), and German-Austria (see W. T. B. R. 679, issued Apr. 2, 1919).

Buffalo Meeting of the American Chemical Society

Report of Acts of Council and Technical Sessions—Best Attended Meeting in the History of the Society—Sessions Enlivened by Successful Smoker and Banquet—Symposiums on Library Service and Mustard Gas

THE 57th meeting of the American Chemical Society at Buffalo was called "Victory Meeting," and it was very largely attended.

Meeting of the Council

The Council was called to order at the University Club at 4 p.m. on Monday, April 7, there being ninety-two Councilors present, the largest number that ever has been counted at one meeting. Aside from routine business, provision was made for specifications for standard laboratory apparatus and for specifications for a standard polariscope. The German instrument which was formerly used by sugar chemists differs from the French type, and presents some undesirable irregularities. A committee is to devise and recommend specifications.

It was agreed to urge as a basis for governmental action the appointment of a high commission to coordinate the natural resources of the country, and it was recommended that in the proposed international councils of chemistry both pure and applied science be included as component parts of it, rather than that their spheres of activity be divided. It was also urged that neutral nations be invited immediately to participate in the deliberations of the body, and to be represented in its membership. A division of Rubber Chemistry has been added to the Society, and it was announced that a Dyestuff Section, of which Dr. C. L. Reese is chairman and R. Norris Shreve secretary, will function at the September meeting in Philadelphia. Reports of many committees were read.

It was decided that all papers presented at any meeting of any section are properly available for publication in the Society's journals and may only be released under permission of its editors.

During recess, at the invitation of the Western N. Y. Section of the Society, the Council dined at the University Club, and immediately afterward resumed its session.

Discussions of Reports

The evening was devoted to discussions of reports, among which was one on Co-operation Between Industries and Universities, and one on Compendia of Chemical Literature and that of the Clearing Committee. The report on Compendia, presented by Dr. Stieglitz, proposed that American chemists take up the preparation of critical volumes on physical and chemical constants and related numerical data (besides certain monographs in other fields as specified). This will leave to the British Commission the preparation of compendia of inorganic and organic chemistry, and to the French Secretariat of the International Commission on Annual Tables of Constants, etc., the continued compilation of non-critical abstracts of constants, numerical data, etc. Convincing reasons for this subdivision of the work were given. The business control of the publication it is proposed to vest in these trustees.

It was in December last that President Nichols called a meeting of the Council to consider proposals in relation to reconstruction. The proposals were at once so multitudinous and miscellaneous that they were referred to an omnibus or clearance committee of which Dr. Arthur D. Little was chairman. The committee laid away in cold storage a large number of recommendations that were evidently designed for other worlds than this, and proceeded to work out into definite shape and form, those that might, could, would or should be undertaken. The whole series offered enough opportunities to appease the most insatiate workers, with

American Falls | Goat Island | Horseshoe Falls | Niagara Falls Power Co. | Victoria Park

enough left over to last, as somebody said, about a hundred years. It is to be printed and circulated for discussion later.

The General Meeting

On Tuesday morning, April 8, the general meeting was held in the ballroom of the Hotel Statler at 9.30 o'clock. There was standing room only, and not much of that. The reason for this was due to the habit of members of the Society to refrain from advising the secretary whether they intend to be present or not, and then coming in great numbers. Out of a total registration of 1150 only 150 had signified to the secretary their intention to be present. The contribution of CHEMICAL & METALLURGICAL ENGINEERING of a printed registration list in convenient form which appeared every afternoon seemed to find favor. It gave the name and address in Buffalo of every registrant.

The HON. GEORGE F. BECK, Mayor of Buffalo, made a short speech of welcome in which, possibly instigated by the threatening rain, he expressed regret that the Society had chosen a season for its visit when the climate of the city was less attractive than at other times. Those who are familiar with the cold blasts of Lake Erie in the Fall and Winter were content to be present in the Spring. He cited statistics relating to the city among which was contained the information that in 1828 one-third of the traffic of the Erie Canal was taken up with the transport of whiskey.

DR. NICHOLS responded in his usual happy manner, after which, in a business meeting that followed, PROFESSOR GIACOMO CIAMISIAN of Bologna, Italy, was elected an honorary member.

DR. (LIEUTENANT-COLONEL) WILDER D. BANCROFT, who is the first of the annual chairmen of the Chemical Section of the National Research Council, reported that that body will now continue its activities on a peace basis. He announced that the Rockefeller Foundation had set aside $500,000 to be spent within the next five years for fellowships in research in chemistry and physics. The minimum fellowship is to be $1500 annually, and it is intended to make these the equivalent of post-doctorate fellowships, although it is not demanded of aspirants that they have Ph.D., or Sc.D. degrees. There are no strings whatever attached to the offer. Anybody who has research in hand or under consideration may apply. He may choose his own subject and his own institution of learning, subject, of course, to the approval of the committee which has the matter in charge. It is hoped to continue good men in research on some problems for terms of two or three years, so that work may be brought as nearly as possible to completion. The committee is ready now to consider applications. It is really an extraordinary opportunity. All that is required is qualification in scholarship and ability, and merit in the subject. Applicants should address Dr. Wilder D. Bancroft, Chairman Division of Chemistry, National Research Council, Washington, D. C.

The President made an appeal on behalf of the children of French chemists and engineers who, as officers, have fallen in the war. This supplemented a similar appeal from Secretary Parsons at the meeting of the Council.

President Nichols' Address

PRESIDENT NICHOLS then made a short address on reconstruction. He declared that the way in which reconstruction problems are solved will be of vast influence, either for good or for evil, for the next century. Without doubt peace terms will soon be agreed upon, and we then should prepare ourselves for peace. Until lately public and private interests have been subordinated to winning the war. In making the change we must bear the public welfare in mind, and remember that we cannot possibly return to the conditions of five years ago. Awful damage has been done, and things cannot be made the same as they were. Revolution has been in process for some time, and revolution can be just as effective, even if we see but little of it on the surface, as if it were to march with plumes and banners. Great changes have taken place, among which we must count the enormous additions to public debts which are said at present to exceed $315,000,000,000. Now the honest thing to do with debts is to pay them, and reconstruction must look forward to eventual liquidation.

SHOULD SEEK PATH OF WISDOM ON LABOR QUESTION

Many employers have been disposed to regard their employees merely as so many hands. Now the pendulum is swinging the other way, and labor is at times disposed

to hold that leadership and the administration of industrial affairs rest solely within its councils. It is our business to seek the path of wisdom, and not alone to find it, but to demonstrate that only by the earnest co-operation of labor and capital, working in harmony and not at cross-purposes, can industry endure. We must bear in mind that quality of product, efficiency of work, and right living under wholesome conditions, are important things, and that wages are subsidiary to them.

Another silent revolution has been the change in the character of our population within the last fifty years. Many of our new citizens have brought with them old-world theories of the inviolability of force.

Prohibition, which we awoke one morning to find all inscribed upon the Constitution, is not a subject the merits of which we should discuss at this place. But we must beware lest so important a material as ethyl alcohol be legislated out of industry as well as out of drink.

The conservation of our national resources, including water power, forest products, and many other sources of wealth, is a very pressing question. Dr. Nichols urged all present to read an article in the March number of the *Atlantic Monthly*, by Dr. Arthur D. Little, entitled "Developing the Estate," to learn of our wasteful extravagance, and of what we should do to prevent it. He expressed the opinion that our great stores of sulphur should not be used where pyrites and sulphurous ores could be roasted to provide what is needed, and he believed that the great opportunities for chemists is to be found along the lines of conservation.

In regard to unrest among workers he pointed out that many employers have been guilty of unfairness. There has probably been less of this than many suppose to be the case, and the condition of the worker has been constantly improving for as long a time as he could remember. Nevertheless the unrest continues. Now, if the present system results in continuous improvement, it is a fair question to ask why it should be changed, as many demand, for something which, as evidence shows, produces nothing but sorrow and destruction. He believed that the only affirmative answer to this is to be found in the propaganda of men and women who can make an easier living by talking than by working. During the reconstruction period we must demonstrate conclusively that our present civilization is based on justice and equity for all. By this means we can set at naught the eloquence of the professional agitator.

Tariff Commissioner Culbertson

The Hon. William S. Culbertson of the U. S. Tariff Commission spoke on "American Chemical Industries and the Tariff Commission." The two outstanding forces which modified chemical industry during the war were the isolation of the Central Powers and war orders. The American public realizes now as it never did before the relation of chemical industries to the national welfare. The month of famine in dyes was the most potent argument it ever encountered in support of this thesis. There were other problems, however, which had to be met, and which were met, but were, of course, less spectacular. Among these were chlorine and chlorine products, barium salts, caustic soda and many others. The speaker thought that the importation of monazite sands from Brazil to make thorium nitrate, in Germany, and the following exportation to this country as gas mantles or preparations for mantles, was one of the most illuminating examples of how not to conduct an industry—so far as America was concerned. And the speedy development of the rare earth industry in this country under pressure of need he regarded as even more illuminating—as showing how things should be done.

The same conditions that obtained in this country operated also in Great Britain, Norway, Sweden and Japan. They have been busy to capacity, supplying war needs until lately; and now they must look for other markets. Investigation of commercial policies is greatly needed, as well as an assemblage of facts related to them.

The war solved some problems in chemical industry, and it created others. It also taught us certain things, among which we may mention for example, the fact that a policy of *laissez faire* has no place in chemical industry.

In the mind of the speaker there is no question that the coal-tar dye industry needs protection. As soon as hostilities ceased Great Britain took steps to conserve her own dye industry by prohibiting all imports of dyes, except such as are authorized by a licensing board, Mr. Culbertson felt that we cannot adopt such a measure, and that we must find our safeguard in the tariff. Our industry is doing business on a lively scale, but it cannot be expected to be able to accomplish in four years what the Germans did in forty to fifty years. The Germans have the advantage of priority in the art, and they have always taken advantage of unfair practices. The difference in priority Mr. Culbertson believed could be met by the tariff, and such unfair practices as bribery and full-line-forcing by the Bureau of Foreign and Domestic Commerce. But dumping surplus stocks at less than cost to gain a market is another problem, and in order to meet this Mr. Culbertson proposes that the tariff law be supplemented, giving the President extraordinary powers to prohibit importations and to increase duties on all materials which he has reason to believe would be sold with a view to destroying competition.

Mr. Joseph H. Choate, Jr., on the Chemical Foundation

Mr. Joseph H. Choate, Jr., general counsel to the Chemical Foundation, spoke on "German Methods and Our Present Situation." He said that the efforts of the Alien Property Custodian had centered in the beginning on the dye industry, so far as chemicals were concerned, and that pharmaceuticals followed. Heavy chemicals in the U. S. seemed to be generally free from German ownership.

In regard to dyes the Germans held in substance a world monopoly, acquired by a combination of natural advantages, and sub-natural methods. They had cheap and docile labor and cheap chemists. They could combine into any kind of a tangle they desired, and the more they interlocked the better the government liked it. First they made two great trusts, and in time the twain became one. Manufacturing on a large scale brought down production costs, which gave a large surplus for export, and the government liked this too. The big trust was formed avowedly for foreign trade, and it has available capital of about half a billion dollars. It is a mighty power.

In the United States they found the dye business permeated with Germans and German chemists, but there was hardly a sign of German ownership, except

among three concerns which reported German ownership. This amazing manifestation of German integrity almost stunned them at first, but, after diligent search, an example of its working was discovered, in the Bayer Co. This concern had an enormous fund from goods sold in the East which could not be remitted to Germany. Among the many uses to which this fund was put was the secret purchase of a nice little going concern known as the Williams & Crowell Co., to which all the assets were being quietly transferred, so that when the Alien Property Custodian should take over the German-owned agency, he might receive an empty shell. When he included the Williams & Crowell Co. in his seizure there ascended unto the skies a high and mighty wail. Hoechst, Cassella and the Badische claimed to be owned by Americans, and the speaker believed that a great hazard to American industry was averted when the actual participation of the German trust in these concerns was smoked out. The Badische interests, for instance, were shown to have belonged always, from the very beginning, to American agents in New York. There was no record anywhere that the German company had been interested. But the remittance of $1,250,000 as dividends by the American agents to the Badische Co. within a rather short period of time was sufficient evidence to convince Mr. Palmer that the Badische Co., after all, was interested. The Hayden Chemical Co. and the Bauer Chemical Co. transferred their stocks in February, 1917, to their general counsels, but the purchasers did not pay for them. German ownership has been pretty well brought to light, he believes.

How Best to Protect American Industry

But there remains the great trust. What has it been doing during the years of the war? Of course we don't know, and without doubt some of its branches have been making munitions. It is fair to believe, however, that vast quantities of cotton vat and other much-desired dyes are stored up, ready to be thrown upon the market here at any price. Mr. Choate did not see how a tariff alone can protect the American dye industry. The German trust can afford to buck up against a 100 per cent tariff, and finally control the situation. He believed the industry in this country to be in a precarious condition, and said that in considering the matter the Alien Property Custodian had come to the conclusion that the only way to stave off a recurrence of the German monopoly was by seizing their patents and preventing control from that source. The Chemical Foundation was therefore formed which purchased in fee all German chemical patents from the U. S. Government, for $250,000. As an organization designed to benefit chemical industry in the U. S. it is hoped that as time goes on the Foundation may buy other patents and continue indefinitely to sell rights under them. But all of these measures will not suffice, in the views of the speaker, to conserve the industry against an antagonist so strong and unprincipled as the German syndicate, unless our Government follows the lead of our British cousins by taking the bull by the horns, and prohibiting imports of dyes, save under a specific license in each individual case.

This was followed by a very pretty little tilt at argument in which Mr. Choate favored the license system and Mr. Culbertson opposed it, in the belief that a proper tariff provision would be an adequate protection for the United States.

Mustard Gas Symposium

On Tuesday afternoon there was held a symposium on Mustard Gas, in the auditorium of the Technical High School. It covered the ground so thoroughly that it became necessary to continue the discussion over to Wednesday morning, drawing a large attendance. Space forbids our reporting the papers in detail, but we cannot suppress the wish that the entire proceedings might be recorded in a separate volume. Despite what appears to be the conclusion of certain governmental authorities to break up the Chemical Warfare Service by extracting the chemistry from it, separating defense from offense, destroying the works, and vesting whatever authority may remain in men with neither training nor experience nor interest in chemical warfare, we know that chemical warfare is here to stay. To the nation at war that is not prepared against it it assures certain defeat, while to the army that is prepared, it is the least dangerous and most humane of all methods of attack. In the interest of the general welfare the chemists of the country should preserve as much as they can from the official discard.

Divisional Meetings

On the morning of Wednesday, April 9, the Divisional Meetings began, and the most important paper of the whole convention was then presented by Dr. Irving Langmuir of the General Electric Laboratories, before the Division of Physical and Inorganic Chemistry, on "The Arrangement of Electrons in Atoms and Molecules." A well-known chemist declared the occasion to vie in importance with the first presentation by John Dalton of his atomic theory. Dr. Langmuir spoke for an hour and a half, before an audience that crowded nearly every square foot of space, and he spoke as one inspired. Later numbers of the journal of the Society will print his exhaustive presentation of the subject, but we are sure that all his hearers will remember the occasion. He started with the theory of "The Atom and the Molecule" as presented by G. N. Lewis, and followed it as far as it went. Then, by a series of postulates, which we shall not repeat because they would require explanatory comment to bring them into correlation, he arrives at a structural theory of the atom which becomes a complete working hypothesis, explaining valence, the irregularities of the periodic law, compounds of the CO type, and the theory of Werner. So profound was the impression made by this masterly presentation, that by urgent request it was repeated on Thursday morning before the Division of Industrial Chemists and Chemical Engineers in the auditorium of the Technical High School.

Preferential Catalyses in the Purification of Hydrogen

Professor H. S. Taylor of Princeton followed with a short talk on "Preferential Catalyses in the Purification of Hydrogen" which contained an interesting statement, and a suggestion that is well worthy the attention of industrial chemists. He desired to oxidize CO, contained as an impurity, to CO_2. With Ni he oxidized hydrogen also, to water, but FeO_3 he found to be selective. Trouble was the process was slow. By mixing two catalytic agents in the proportion of 85 to 15, viz.: FeO_3 and Cr_2O_3 the reaction was speeded up 700 times. Professor Taylor urged further research along the lines of these catalytic boosters, in the interest of better chemical control in technology.

In the Division of Industrial Chemists and Chemical Engineers the proceedings began with a series of twelve papers on Library Service in Industrial Laboratories. The contributions were from librarians engaged with the Carnegie Library of Pittsburgh, Dr. George W. Crile, Eastman Kodak Co., the Chemical Catalog Co., Arthur D. Little, Inc., National Aniline & Chemical Co., Inc., National Carbon Co., N. J. inc Co., Stone & Webster, the Solvay Process Co., The Barrett Co., and E. I. du Pont de Nemours & Co.

Uses for Libraries

Limitations of space again forbid details, but possibly the following argument may roughly cover the ground. If men are to work with their minds with a view to making needed things as well as possible, and as cheap as possible, it is part of the game to let them learn what others have accomplished along similar lines. The information is contained in periodicals and books. These are valueless unless they are available, and they are not available unless each is to be found in a particular place on a particular shelf. When this situation has been reached a library results. Now library service consists in telling the man who wants to know in which book or paper he can find the information he is seeking, and where to look for these. Titles often are misleading.

Other Papers

Dr. Adams T. Clarke told of the joys and sorrows of producing unusual organic compounds for chemical research, and expressed his obligations to many manufacturers for their assistance. Dr. W. J. Hale of the Dow Chemical Co. followed with the opinion that manufacturers should do more; that they should send their products freely, and that they should purify the materials themselves, as far as possible, which is often a much cheaper process for the original maker than for Dr. Clarke in his establishment. He wanted to see the prices for pure chemicals brought down.

Dr. A. G. Peterkin presented a paper on phenol, in which he reported 8,000,000 lb. as the annual pre-war consumption in the U. S. This was chiefly imported from England. During the war manufacture increased to the rate of 150,000,000 lb. annually, of which not over 2,000,000 lb. was distilled direct from coal tar. The Government now has from 30 to 50 million lb. on hand, and uses for it are wanted. When present stocks are absorbed there should be use for the output of one or two phenol plants in this country.

Dr. Paul Rudnick gave a series of tests of metals held in couples in solutions of $CaCl_2$, which are offered for sale as motor car anti-freezing mixtures. In many cases the metals held up well for eighteen days, but lost in weight seriously the ensuing week. His conclusions were not favorable to the use of $CaCl_2$ in automobile anti-freezing mixtures, and this was confirmed by a majority of those who followed him in discussion. One member had reached like conclusions, and had advised against such a mixture, but his advice was disregarded, and after two winters the old machines were still in running order. Against this, however, many machines were reported as seriously damaged after short use of such mixtures. Aluminium suffers most from them.

Three Papers by Dr. Baskerville

Dr. Charles Baskerville presented three papers. The first was on lead-coated iron sheets which were free from pin-holes. A roof made of this material has been exposed to the weather since 1914, and is still good. The second was a reinforced lead, of which he showed examples in sheets, similar to wire glass in its reinforcement. Seven-inch vacuum mains made of this material showed no tendency to collapse. The third paper had to do with "Utilization of Asphaltic Base Acid Sludge from Petroleum." The sludge is treated in the following manner: After heating to about 120 deg. F., the sludge separates into three layers, of which the bottom is concentrated acid, and is recovered. The middle zone contains the asphaltic bodies, which are washed with water, and treated with lime. A useful asphalt paper was shown, made of this recovered material.

Mr. R. O. E. Davis gave results of his work, showing difficulties in connection with CO in the Bucher process. The effects were found due to the small amount of CO_2 that is always in equilibrium. Eight-tenths of one per

cent of CO_2 totally inhibits the yield of fixed nitrogen. Four-tenths of one per cent permits a yield of 60 per cent, and the presence of one-tenth of 1 per cent or less has no effect. One of the mysteries still to be solved in the Bucher process is to determine what the product really is. It is neither a cyanide nor a cyanamide, but rather a mixture of several nitro carbides which have not yet been isolated and determined.

Social Features

The smoker on Tuesday night was about the liveliest entertainment of the kind we have ever attended. The chairman of the committee, Mr. F. A. Lidbury, is not given to inertia in the presence of opportunities to crack heads, and on such occasions he is no milder than a man from Kildare with a blackthorn. Nobody was safe after his name was called.

On Wednesday evening at 6 o'clock the members of the Council were entertained at dinner by one of their number, the Rev. M. J. Ahern, S. J., President of Canisius College, in the refectory of that institution.

At 8.30 on the same evening Provost Edgar F. Smith of the University of Pennsylvania delivered a very scholarly address to a large body of members and guests of the Society and Buffalo citizens in the auditorium of the Hutchinson High School, on "A Chemical Story." He brought out how the phlogiston theory met its original defeat in Philadelphia, at the hands of young James Woodhouse in argument with Joseph Priestly. He also gave a remarkable list of American origins in chemistry and physics that have been forgotten in the literature, and he made an earnest plea for their incorporation in text-books. Why American scholarship seemed to pass under a cloud in the first half of the nineteenth century and to forget even its own, is an interesting question which the good Dr. Smith did not undertake to answer—and this is no place to discuss it.

On Thursday evening the banquet was held, at which Mr. Lidbury presided as toastmaster. In this post he was almost as gentle as a dove—and yet not quite as gentle as a dove. There were many speeches, but none of them long. The toastmaster had a stop-watch and a bell.

Seeing Chemical Plant Apparatus Made

THE addresses and papers of the Spring meeting of the American Chemical Society at Buffalo were followed by exceptionally interesting plant visits. That to the Schoellkopf works of the National Aniline & Chemical Co. should prove an inspiration to the 1100 members in attendance. Though they could have stayed home and perhaps ultimately read in their publications the hundred-odd papers given at the sessions, they never could have received the personal enthusiasm for American chemistry that would have resulted from seeing and then believing in our own industrial efforts.

After being informed that the annual production of dyes in the Schoellkopf plant had been pushed from 2,000,000 to 22,000,000 lb. during the war; the rapid and partial inspection of the works through huge boiler, power and refrigeration plants, and by batteries of mixing machines, autoclaves, filter presses, tanks, stills and condensers, all as compact as extensive, can convey no more than a general impression of the great quantities and types of apparatus used there.

The plant of the Buffalo Foundry & Machine Co. was of especial interest to the industrial chemists on the tour, for here is made Buflokast and Buflovak chemical apparatus. Believing that the attendance represented but a very small part of those keenly interested in seeing chemical apparatus made, we take this opportunity to carry a few views and notes to our readers, in the hope that they will find them of value.

Melting Iron for Casting

Two types of cupolas are used in this foundry. The air furnace is reverberatory and has the advantage that the molten metal does not come into contact with the fuel impurities such as pyrite sulphur. Eight hundred thousand cubic feet of air (64,800 lb.) is used in this furnace per hour, consuming about seven tons of coke and producing 27 tons of molten iron. Since the heat generated by a pound of coke should theoretically melt about 40 lb. of iron, assuming that the combustion and absorption be perfect, it will be seen that an ideal efficiency of only 10 per cent of the heat energy is

SWEEPING FUSION POT CORES

obtainable. Fluorspar is used as a flux in some cases, and white marble chips in others. A tuyere area equal to 31 pipes of 6-in. diameter is required. Ten inches clearance is allowed between them and the sand floor of the cupola. The other cupolas are of the standard foundry type and have a 15- and 10-ton capacity per hour each.

Making Cores

The characteristic of almost all chemical castings is that they require unusually large cores. Containers holding as much as 400 cu.ft. are ordinary. Both the design and size of the cavity in the casting is obtained by properly suspending and submerging the core. The latter operations are by no means simple. The buoyancy effect of the molten iron, which is about three times heavier than the core material per unit volume, has to be overcome by large iron weights, more than twice as heavy as the submerged core.

The illustration of the fusion pot cores shows the materials and method used in building cores. The center is built up of brick and mortar reinforced with iron rods and ties. Over this a refractory loam is applied and shaped by a revolving sweep, having the center of the core as axis. When the design is finished, the core, which has been built on a car, is run into a drying kiln and fired to remove all moisture. This is very important because water will not only chill the iron too rapidly but gases excessively—expanding about 9000 times in volume. Upon taking the core from the dry kiln, small drying checks are finished over with a special preparation, which imparts a smooth and very refractory finish.

DISSOLVING TANK MOLD

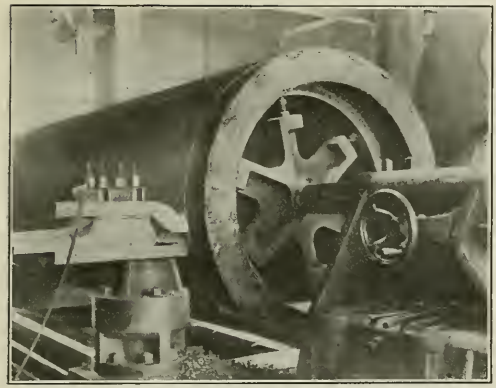
Sweeping Molds

Patterns, sweeps and shaping tools with the skill of the molder are all in need. The illustration shows the mold for a 14-ft. 4-in. dissolving tank in preparation. The sweep for shaping the cylindrical walls and the pattern shaped ribs in the bottom can be seen. The depth of this casting is about 9 ft. As molten iron has a fluid pressure about seven times as great as water, the need for deep pit casting is evident. The ground is well vented with cinder bedding and pipes. The walls of the finished mold are torch baked and finished off similarly to the core surfaces.

POURING A HIGH RISER CASTING

Pouring Castings

After the core has been properly centered and weighted, the ladle is filled with the required amount of metal. The channel for the inflow is connected with the base of the mold and in this way a minimum amount of abrasion of the earth walls is obtained during the pour. The illustration shows a 35-ton ladle being poured with an extra high riser. This is a special feature with these products and makes castings under great liquid-metal head pressure as well as furnishing



MACHINING VACUUM DRUM

large risers in which most of the entrapped sand, gas, etc., is segregated to be removed later. The iron flask rings are lugged together. The small flame shooting from the joints is the gas distilling from the loam, which has been heated to above its kindling point.

The excess metal in the riser is readily removed in a lathe, the operation of which is shown on a drum in an accompanying illustration. In the case of drums, an excess of surfacing material is cast also which is removed at the same mounting on the lathe. In a similar manner, all parts which require perfect lines and surfaces are machined in either a planer or lathe.

The grain of the metal will depend largely on the time of cooling, which will be controlled by the heat of the pour and the time allowed before the casting is stripped. Where a hard and fine grain is desired, the mold is stripped while still at a high heat and the casting air cooled. The core is pulled apart and not taken out whole.

Silicon irons are used where resistance to acids is desired, though time does not permit details to be described here regarding the compositions of each special type of chemical resistant metal. However, special alloys are always prepared under the direct guidance of the metallurgical laboratory to meet the requirements to which the apparatus is to be put in use.

Sizes of Apparatus

As far as the foundry is concerned, there is practically no limit in the size to which castings can be made. Transportation facilities alone govern weights and sizes. For instance, the two dissolving tanks shown on the car weigh but 21 tons each, nevertheless there was only one route out of the several available which had bridge clearance sufficient for them to pass in order that they could reach their destination at Perryville, Md. So 14-ft. clearance can be seen to be the exception rather than the rule. As for weight limits, special six-truck cars are available with well over 100-ton capacity. No single piece of apparatus is likely to stay within the limits set by the car clearances and even approach this weight.

However, industrial chemistry is always demanding larger and larger equipment, and a new method of transportation that is capable of accommodating even the large 400-ton cranes of the foundry has come into vogue. This is by water, through the canal, lake and river route. If the huge ocean liner, the stern half of which is shown on its way to the ocean, only has to be cut in two to meet the water route clearance limit, what chance will the railroads have when really large apparatus is demanded?

Research Laboratories

The research laboratories are composed of two main sections, analytical and mechanical. The first comprises the various chemical laboratories, which are maintained for conducting the analytical work connected with the research department. The second consists of the mechanical testing laboratories containing working units of various apparatus, where practical tests are made on customer's materials to determine the apparatus best adapted to them.

These laboratories are in charge of chemists, metallurgists and experts who are thoroughly experienced in the chemical processes and mechanical operations involved in the use of apparatus.

Vacuum Laboratory

The various determinations pertaining to experiments in vacuum drying and evaporating are performed in the vacuum laboratory. Here are also kept complete records of all tests, with samples of some of the materials tested in various stages of the evaporating or drying process. Information and data pertaining to tests are treated in strict confidence and never divulged except to those entitled to them.

Physical Testing and Microphotographic Laboratory

This laboratory is an example of the care and thoroughness observed in manufacture of this type of apparatus. Not only are all raw materials analyzed chemically, but in addition a tensile test is made on samples of all finished products, which are also microscopically examined by means of the microphotographic camera.

The proper metal mixtures and other data required in the production of the castings used in this work are determined in the metallurgical laboratory before the work is taken up in the foundry.

LARGEST TANKS EVER SHIPPED BY RAIL

Another example of the completeness of the laboratory equipment is the laboratory cupola, a part of the metallurgical laboratory equipment. By means of this cupola metallurgists are able to make actual samples of various metal mixtures for testing to determine the mixture best suited for the purpose intended.

A small electric furnace is also in this room for laboratory experiments in electrometallurgy. Work of a larger scope in this field is carried on in the electrometallurgical development department, adjoining the main foundry.

Testing Laboratory

The testing laboratory contains working units of various apparatus, including each standard type of vacuum drier and evaporator, thus making it possible to conduct experiments on each type, if necessary, to determine the one best adapted for the material being treated.

The apparatus used is of small commercial size, and any results obtained can be duplicated, except as to quantity, in the larger sizes.

Wet Vacuum Pump. Used for producing ordinary vacuum on evaporators. When a high vacuum is required the evaporators are connected to one of the dry vacuum pumps.

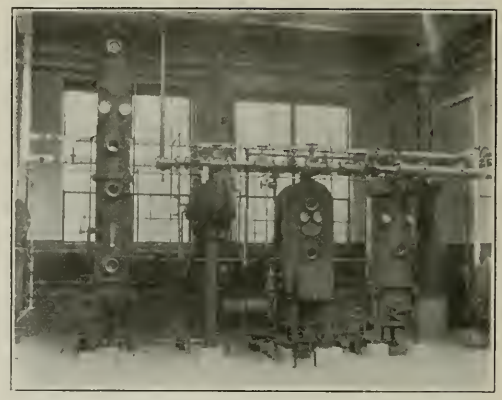
Surface Condenser. Used with evaporators when they are being operated under high vacuum with a dry vacuum pump.

Vertical Tube Evaporator of the Crystallizing Type. Used for evaporating solutions containing salts which become insoluble during the concentration. This small evaporator is equipped with a single filtering device at the bottom, but on larger types two or more salt filters are provided, which can be used alternately without interrupting the operation of the evaporator as each salt filter requires emptying.

Horizontal Tube Evaporator. Used for common solutions which are to be distilled or concentrated to higher densities without the separation of salts, and which have no tendency to foam or produce scale.

In the sizes built for general commercial work the shells are cylindrical. An important advantage of this construction is the possibility of increasing the capacity by simply adding another cylindrical shell and providing longer tubes. This avoids the necessity of installing entirely new equipment when more capacity is required. The shells are made in one piece up to 12 ft. long, thereby reducing to a minimum the number of joints and the chances of leakage.

OCEAN LINER CUT IN TWO BEING CARRIED TO THE SEA



SECTION OF LABORATORY SHOWING HIGH CONCENTRATOR, RAPID CIRCULATION, HORIZONTAL TUBE AND VERTICAL TUBE EVAPORATORS

Rapid Circulation Evaporator. This type is especially adapted for evaporating foamy and delicate liquors. It is economical and capable of high capacities. A special feature of this type is the fact that it can be operated with very small temperature differences, on which account it can be used in multiple effects of many units. This makes for high economy in steam consumption and large capacity of liquor handled.

Other features are as follows: High liquor velocity in the tubes, easy cleaning of tubes from the outside, liquor losses on account of foaming or entrainment reduced to a minimum, large capacity per sq.ft. of heating surface, simple operation. It is also noted for its high efficiency, uniform circulation, substantial construction and moderate cost. The amount of liquor in circulation is very small and the possibility of foaming is reduced to a minimum, as the liquor level is always kept low and the foam is broken up in the upper part of the tube where film evaporation takes place.

High Concentrator. Especially adapted for the high concentration of caustic soda, potash, ammonium nitrate and electrolytic caustic solutions above 36 deg. B. This evaporator produces a very rapid, uniform circulation of the liquor and it is possible to concentrate to high densities that are not possible with evaporators of standard construction.

The high concentrator is also used for liquors separating salts, and especially caustic solutions at high densities, where an all-cast iron construction is absolutely necessary. The tubes are made of alkali- or acid-resisting iron depending on the nature of the liquor to be concentrated. The evaporators can be operated under atmospheric pressure or under a vacuum as may be most suitable for the material being handled.

Special Vacuum Drum Drier. For drying pasty substances. This drier is now in the process of development.

Crystallizer. This apparatus can be operated with or without a vacuum. The jacket is cast integral with the pan, this construction being also followed in the larger sizes. This eliminates all joints as well as the use of bolts, packing, etc. This apparatus can be used for concentrating and crystallizing a great variety of products.

Vacuum Rotary Drier. Used for drying materials that permit mixing or agitation. The interior is equipped with mixing arms and paddles attached to a revolving shaft. In larger sizes this shaft is also a heating tube which assists in the drying.

Vacuum Drum Drier. In operation, converting milk from liquid state to dry form. This drier is also used for drying many other liquid materials. Besides being used on experimental work, this machine is also used commercially for drying smaller quantities of material than can be handled economically in the large apparatus. The results obtained on this machine can all be duplicated, except as to the quantity, on the larger sizes.

Laboratory Shelf Drier, Small Size. This is used very extensively in laboratory and research work. Many concerns use it for conducting tests on their own materials and also for determining in advance how deep to load pans for their larger driers. In this drier the center of the stand forms the condenser, and the base a receiving chamber for condensed vapors.

Circulation Pump for Circulating Hot Water. In making drying experiments it is often necessary to use hot water as a heating medium. This pump is connected to all driers for this purpose.

Dry Vacuum Pump. Two-stage, steam-driven. The arrangement of the piping on this and the single-stage is such that either pump can be connected to any piece of apparatus in the testing room, this permitting the operation of any apparatus with a single- or two-stage pump as desired.

Surface Condenser. The surface condensers are connected to all apparatus. They are so arranged that any valuable solvents from materials being dried may be recovered, and also drained from the condensers without interrupting the drying operation.

Expansion Tank. Used in connection with a dry vacuum pump to collect and reclaim highly volatile vapors which sometimes pass through the cylinder of the vacuum pump with the exhaust air from a vacuum apparatus.

Impregnating Apparatus. Used for impregnating any material with liquid compounds, oils, paraffine, colors, etc. Also impregnating electrical apparatus such as coils, armatures, transformers, etc., with insulating compound.

Industrial Research in England

The British Government has placed a fund of a million sterling at the disposal of the Research Department for the purpose of encouraging industrial research. In order that the assistance rendered may be effective in increasing the initiative and independence of the manufacturers, the Advisory Council for Scientific and Industrial Research has recommended that the new fund should be expended on a co-operative basis, in the form of liberal contributions by the Department toward the income raised by voluntary associations of manufacturers established for the purpose of research. That is, if the firms in an industry which are engaged in the production of similar articles, or alternatively, if the firms in different industries which make use of the same or similar raw or semi-manufactured materials, will combine to improve the processes of manufacturing those materials, the Department will contribute liberally to a joint fund for this purpose.

In this manner, a number of research associations may be formed, some treating the problems of a whole industry, while others may limit their activities to a specific branch of a single industry. The expenditure of the fund for each association will be controlled by a committee or board appointed by the firms contributing to the association and the results obtained will be available for the benefit of these firms only. The Government, however, reserves the right of veto in case any proposal is made by a research association to communicate any results of research to a foreign person or to a foreign corporation, and the right, after consultation with the association concerned, of communicating the results of discoveries to other industries for their use on suitable terms. However, no results will be made available to firms or individuals who are eligible for membership in the association in question but have not joined it.

It is hoped and anticipated that these associations, after having received Government assistance during the period of formation, will eventually prove self-supporting and thus make industrial research an integral part of British industry.

Civil Service Examinations

Associate Chemist.—Applications on Form 2118 will be received until further notice. Requirements; Ph. D. degree or equivalent. Entrance salary, $1800 to $2500 a year.

Junior Chemist.—Application on Form 1312 will be received until further notice. Bachelor's degree required. Entrance salary ranges from $1200 to $1440 a year.

Laboratory Aid.—Examinations will be held May 7, June 4 and July 9 at the places designated on Form 1237. Applications must be sent on Form 304. Entrance salary, $840 to $1240 a year.

All of these examinations are open to women as well as men.

American Welding Society

The first meeting of the American Welding Society was held on March 28, 1919, at the Engineering Societies Building, 33 West 39th Street, New York, and the constitution and by-laws were adopted as recommended by the organization committee.

The following officers were elected: President, C. A. Adams, Cambridge, Mass.; vice-president (for 1 year), J. M. Morehead, New York; vice-president (for 2 years), G. L. Brunner, Utica, N. Y.; directors for 1 year, W M. Beard, New York; M. H. Roberts, New York; M. M. Smith, New York; L. D. Lovekin, Philadelphia; Alexander Churchward, New York; W. H. Patterson, Pittsburgh; Walter J. Jones, Philadelphia; C. A. McCune, New York; directors for 2 years, R. R. Browning, New York; A. S. Kinsey, Jersey City; Victor Mauck, Conshohocken; E. L. Hirt, South Bethlehem; J. F. Lincoln, Cleveland; H. M. Hobart, Schenectady; D. C. Alexander, New York; H. R. Swartley, Jr., Jersey City; directors for 3 years, L. H. Davis, New York; E. L. Mills, New York; D. B. Rushmore, Schenectady; James Burke, Erie; D. H. Wilson, Jr., New York; Hermann Lemp, Erie; C. J. Nyquist, Chicago; Alexander Jenkins, Baltimore.

At a meeting of the directors in the afternoon, W. E. Symons was appointed treasurer and H. C. Forbes secretary.

National Research Fellowships in Physics and Chemistry

The National Research Council has been entrusted by the Rockefeller Foundation with the expenditure of an appropriation of $500,000 within a period of five years for promoting fundamental research in physics and chemistry primarily in educational institutions of the United States. A system of National Research fellowships is to be established, under the administration of the Research Fellowship Board of the National Research Council, the members of which are the following:

HENRY A. BUMSTEAD, professor of physics, Yale University; SIMON FLEXNER, director of laboratories, Rockefeller Institution for Medical Research; GEORGE E. HALE, director of Mount Wilson Observatory; ELMER P. KOHLER, professor of chemistry, Harvard University; ROBERT A. MILLIKAN, professor of physics, University of Chicago; ARTHUR A. NOYES, director of the Research Laboratory of Physical Chemistry, Massachusetts Institute of Technology; WILDER D. BANCROFT, professor of physical chemistry, Cornell University.

Fellowship Appointments.—Candidates for Research fellowships will include those who are brought to the attention of the board by professors in educational institutions and by other investigators throughout the country, as well as those who apply on their own initiative. As a rule, fellowships will be awarded to American citizens who have had training equivalent to that represented by the Doctor's degree, but in exceptional cases this requirement may be modified. The salary for the first year is ordinarily $1500, but this, too, may vary in individual cases. The results of all investigations conducted by Research fellows are to be made available to the public without restriction.

Fellowship Applications.—It is expected that fifteen to twenty Research fellowships will be available during the coming year, and that the number will be increased in subsequent years. Applications for these fellowships should be made on the form provided for the purpose, and should be sent to the secretary of the Research Fellowship Board, National Research Council, 1023 Sixteenth Street, Washington, D. C., to whom all other correspondence should also be addressed. Applications will be received up to Sept. 1, 1919, for fellowships available during the next academic year; but a limited number of appointments will be made on the basis of the applications received on or before April 20, 1919.

Imports and Exports

The Bureau of Foreign and Domestic Commerce of the Department of Commerce reports the following imports and exports for January, 1919:

IMPORTS BY COUNTRIES AND EXPORTS (TOTALS ONLY) OF LEAD AND ZINC

IMPORTS

Articles and Countries	Gross Weight Tons	Contents, Lb.	Value
Lead ore:			
Canada	507	113,618	$5,762
Mexico	4,731	639,817	26,776
	5,038	753,435	$32,538
Lead bullion and base bullion:			
Mexico	9,885,902	9,678,891	$611,716
Zinc ore and calcamine:			
Canada	1,042	894,752	14,969
Mexico	1,298	1,034,319	21,216
	2,340	1,929,071	$36,185

FOREIGN EXPORTS (TOTALS)

Lead pigs and bars		5,666,988	$516,057

DOMESTIC EXPORTS (TOTALS)

Lead pigs—Domestic ore		4,658,421	360,457
Lead pigs—Foreign ore		12,875,887	886,130
Zinc spelter—Domestic ore		10,680,934	1,047,990
Zinc spelter—Foreign ore			
Zinc in sheets		3,408,051	786,798

IMPORTS OF TIN BARS, BLOCKS, PIGS, ETC., BY COUNTRIES AND CUSTOMS DISTRICTS

Countries	Lb.	Value	Districts	Lb.	Value
England	168,108	$137,491	Buffalo	14,552	$5,576

Effecting and Controlling Crystallization of Ammonium Nitrate

A Description of the Crystallizing Process Employed at the U. S. Ammonium Nitrate Plant—Survey of the Air Conditioning Features Involved and Their Relation to the Entire Process of Refrigeration

By J. ESTEN BOLLING

THE article on the U. S. Ammonium Nitrate Plant which appeared in the last issue of CHEMICAL & METALLURGICAL ENGINEERING discussed in detail the chemistry of the process employed and included a general description of the mechanical operation of the plant.

It is the writer's purpose to describe at greater length the means employed to effect and control crystallization after the liquor leaves the filter presses, passes through the dilution tank and is delivered to the pipe lines.

The entire crystallizing cycle, from the time the liquor leaves the dilution tank until the crystals are removed from the pans, was considered a unit problem and entrusted to the Carrier Engineering Corporation, of New York City.

The liquor, or solution, leaves the filter presses at a temperature of not less than 64 deg. C., being cooled slightly at the dilution tank, and it was decided to pre-cool it to approximately 38 deg. C. before admitting it to the crystallizing pans. To accomplish this the liquor is pumped from the dilution tank to a pre-cooling room where it is passed through a battery of double-pipe pre-coolers.

Cooling the Liquors

These pre-coolers are constructed of 2-in. pipe within 3-in. pipe, the general construction being similar to that of ordinary ammonia condensers, except that a metal spiral was wound around the 2-in. pipe so as to practically fill the annular space between the two pipes. The pitch of the spiral is about 2.5 ft. and it was added to increase circulation, insure uniform cooling throughout the moving column of liquor, and to prevent the inner 2-in. pipe from sagging at the center and thereby causing a variation in the cross-section of the liquor column exposed to the cooling surface. The pipes are 20 ft. long and could be expected to sag considerably, the smaller internal pipe more than the larger external one.

The liquor is circulated through the annular space between the pipes, the cooling water being passed through the inner 2-in. pipe. This was necessary on account of the relative volumes to he handled.

Two batteries of pre-coolers were installed for each unit of four crystallizing rooms, each battery consisting of 5 regular banks and one spare bank. The connections were designed so that any one bank could be cut out of the system for cleaning, without interfering with the operation of the others. When the liquor is drained out the coils can be flushed clean with water, heated by means provided.

A unique feature of the pre-cooling system is, that in order to avoid over-cooling, it is necessary to raise the temperature of the cooling water *above* that at which it is supplied from the mains. The pre-coolers were therefore arranged for recirculation of cooling water, so that a large percentage of the total volume in circulation is recirculated by independent pumps and the required percentage of cooler water admitted by means of an automatically controlled 3-way valve. It should be noted that the cold water supply varies from 0 deg. C. to 29 deg. C. and that the automatic control was designed to constantly maintain the entrance temperature of the cooling water at a degree high enough to prevent "freezing" in case of a complete cessation of liquor flow.

In addition to the automatic regulation of the cooling water temperature, thermostats were placed in the liquor outlets from each bank of coils, so connected that the flow of cooling water is instantly cut off whenever

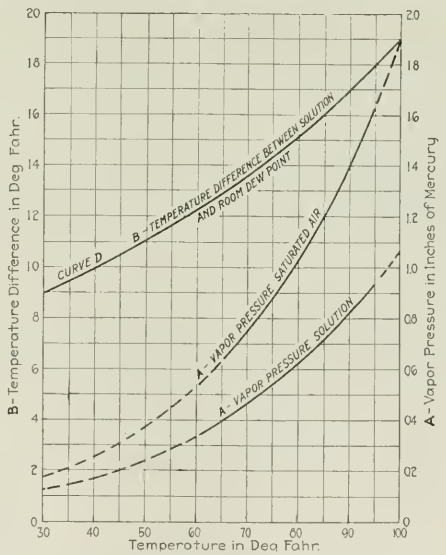

FIG. 1. VAPOR PRESSURE CURVES

the temperature of the liquor drops below the danger point. This was considered necessary because the rate of liquor flow through the coils is determined not by the quantity produced in the digestors, but by the flow into the crystallizing pans, and this flow is variable through rather wide limits, being a hand operation. A condition of complete stoppage was not considered impossible.

The liquor is drawn from the pipe lines into the pans by hand and it is obviously possible for all the pans to be filled at one time so that, for a short period, no liquor would be drawn from the lines. To prevent the freeze which might result under this condition, the liquor feed lines were made in the form of loops which completely encircle the crystallizing rooms. The liquor from the pre-coolers is discharged into an equalizing tank located in the pre-cooler room. From this equalizing tank it is pumped around the loop by independent circulating pumps. These pumps move a volume about twice that which is normally flowing into the pans at any given time, thereby maintaining a constant rapid circulation in the pipe loop. The liquor which has completed the circuit of the loop is returned to the equalizing tank, where it is mixed with pre-cooled liquor from the coils and where an automatically controlled volume of hot liquor, direct from the dilution tank, is admitted to bring the temperature of the entire tank content up to the required degree for safety.

Besides this automatic control of the tank temperature, the liquid level maintained in the tank is governed by a float valve, to prevent overflow. In case the flow into the pans is stopped for a short period the equalizing tank acts as an emergency storage to absorb the fluctuation in flow.

Due to the unusually high temperature of the liquor leaving the filters it is possible to effect nearly two thirds of the total requisite refrigeration in the pre-coolers. The cooling effect of the pre-coolers is equivalent to approximately 1000 tons of refrigeration.

Every precaution was taken to prevent freezing the liquor in the piping system and to this end the design and installation of the entire system was left to the Carrier Engineering Corporation staff of engineers. Dead ends in any part of the piping system were carefully avoided, and means were provided to maintain the liquid temperature in case the flow is stopped, or the system can be immediately drained where necessary, the liquor being stored where crystallization will do no damage.

The saturation temperature of the liquor depends

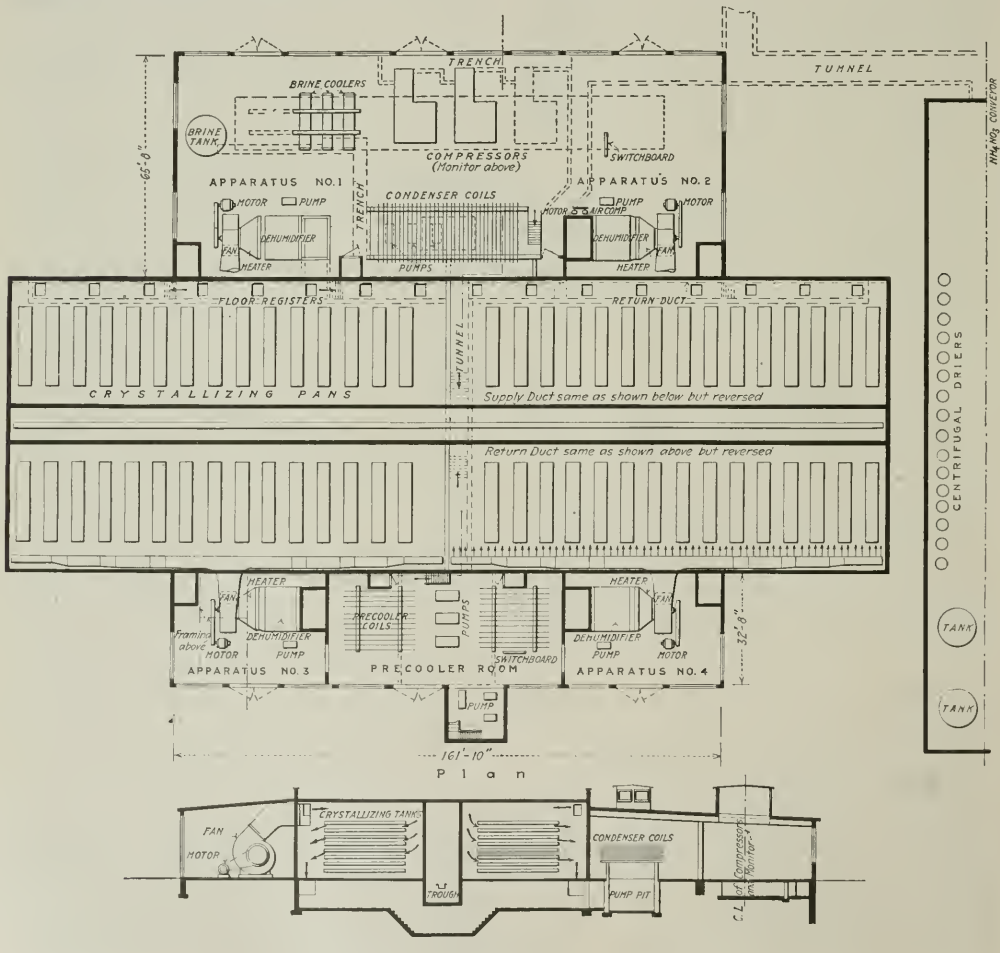

FIG. 2. PLOT PLAN OF APPARATUS

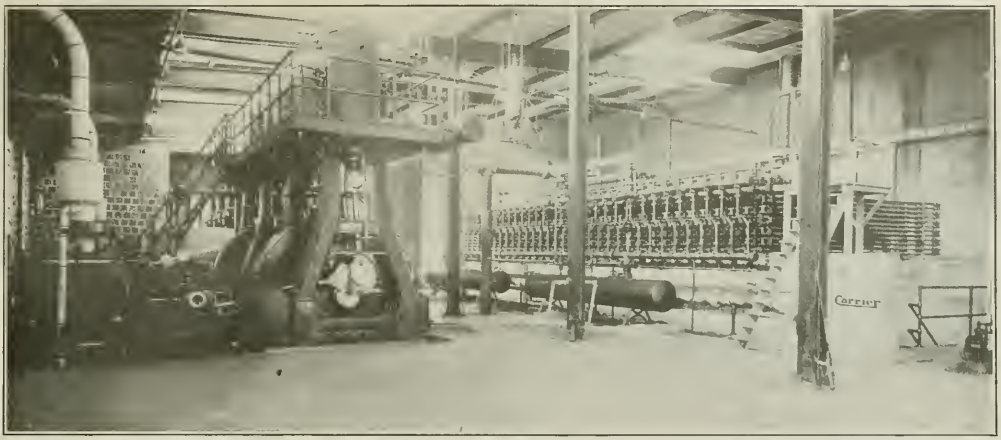

FIG. 3. AMMONIA MACHINES AND BAUDELOT COILS. VERTICAL SINGLE-ACTING COMPRESSORS, STEAM DRIVEN

upon the operation at the dilution tank, and in spite of every precaution it was expected that this would vary considerably. The "safe" temperature was therefore determined for the extreme of this variation and all adjustments made accordingly.

The large pre-cooling coils provide a great excess of hot-liquor radiation in the pre-cooler room and it was therefore necessary to install equipment which would lower the temperature of the room to a permissible degree. Under full operation it is necessary, with the outside temperature at zero F., to introduce cold air in order to keep the room temperature down to 90 deg. F.

For this purpose a small fan was installed and equipped with automatic damper regulation which admits the required volume of cold outside air and recirculates a proportionate volume of air drawn from the room. In summer this fan provides a full volume of outside air, but distributes it uniformly so as to prevent local chilling of the smaller pipe lines or coils, which might be expected if ventilation were obtained through open windows or doors.

Crystallization Department

After pre-cooling the liquor is run into the pans in the crystallizing room.

Due to the very narrow limits between the temperature at which the NH_4NO_3 crystallizes and the temperature at which the other salts begin to crystallize, it is imperative that the cooling be accomplished by the air surrounding the pans, rather than by any form of cooling surface. As pointed out in the previous article, if the filtrate were simply cooled to 20 deg. C. it would be supersaturated with all three salts, NH_4NO_3, $NaNO_3$, and Na_2NO_4, and further fractional crystallization would be necessary in order to separate pure NH_4NO_3. To prevent this sufficient distilled water is added to the filtrate to prevent crystallization of $NaNO_3$ and Na_2SO_4, by lowering their concentration ordinates as is shown in the cycle on page 321.

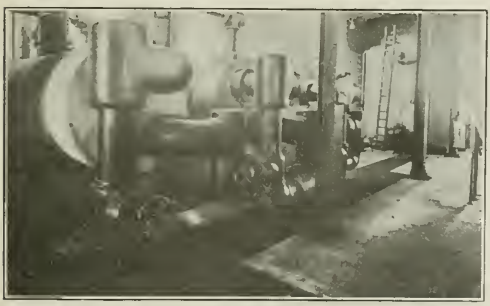

FIG. 4. SHELL AND TUBE BRINE COOLERS

Desirability of Minimizing Evaporation

In order to maintain this balance, which is carefully determined and effected at the dilution tank, and in order to prevent excessive surface cooling, it is desirable to minimize evaporation from the pans, as far as possible. To avoid evaporation it is necessary to maintain a vapor pressure in the air surrounding the pans, equivalent to or greater than the vapor pressure in the liquor at any given temperature while cooling. To maintain this vapor pressure in the air requires a high humidity, since it requires a correspondingly high dew-point. From the vapor pressure curves in Fig. 1 it appears that the highest vapor pressure in the liquor (at 100 deg. F.) is approximately 1.05 in. Hg, while the dew-point necessary to establish a vapor pressure in the air equivalent to 1.05 in. Hg is approximately 81 deg. F., or 19 deg. F. lower. The ideal crystallizing cycle would, then, contemplate an initial dew-point of, say, 82 deg. F. constantly decreasing along the curve "D," so that the vapor pressure in the air would always be maintained at a value slightly higher than the vapor pressure in the liquor. This would prevent all evaporation and still effect rapid and efficient cooling. To accomplish this it would have been necessary to install a Carrier thermotyme regulator and carefully adjust the instrument for the required control. Although the equipment was designed so that a thermotyme regulator could be later installed, it was decided to begin the operation without complicating matters by installing this instrument, production being of far greater importance than efficiency of operation.

A dew-point of 35 deg. F. was therefore fixed, this

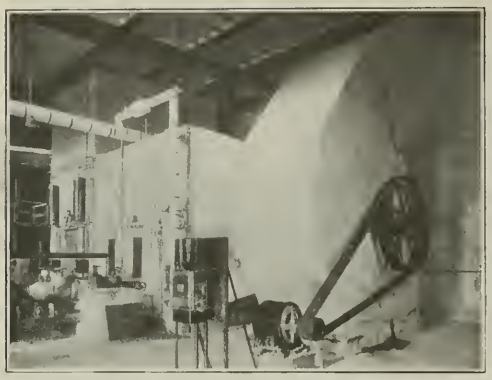

FIG. 5. AIR CONDITIONING UNIT

being low enough to effect rapid cooling and to efficiently utilize salt brine for cooling the air. The dry bulb temperature in the crystallizing rooms was specified at 45 deg. F. (7+ deg. C.) permitting a diffusion of 10 deg. F. This required an air supply of 75,000 cu.ft. per min. to each crystallizing room (or a total of 600,000 cu.ft. per min. for the entire installation), in order to effect the required cooling with the given diffusion (rise in temperature due to heat absorbed from the liquor). To cool the total volume of air to the specified dew-point of 35 deg. F. requires 700 tons of refrigeration.

The crystallizing plant is divided into two main units,

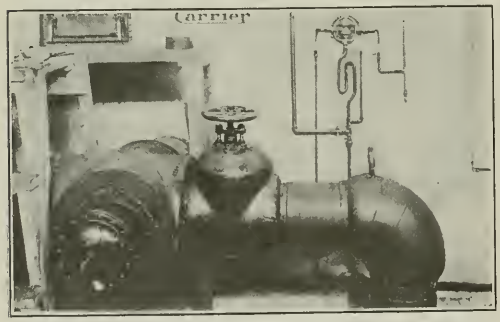

FIG. 6. THREE-WAY VALVE BRINE THERMAL CONTROL

designated as Line A and Line B. Fig. 2 shows a plot plan of one of the crystallizing room units. Since they are exact duplicates this discussion will be confined to a single unit.

Each unit is composed of four separate crystallizing rooms, approximately 36 ft. x 128 ft., each containing 15 tiers of 8 pans each, or a total of 120 pans per room and 480 pans per unit. The volume of each pan is about 40 cu.ft.

The air supply equipment is divided into a separate apparatus for each room, or four complete sets of apparatus per unit.

Refrigeration Equipment

Each unit is supplied with refrigeration from one set of two compressors which supply cold brine to each of the four sets of apparatus. Each compressor set consists of two vertical, single-acting, two-cylinder York ammonia compressors, driven by horizontal Corliss engines (Fig. 3), the machines operating at a suction pressure of about 28 lb. and a head pressure of about 165 lb., and each developing 175 tons of refrigeration, or a total of 350 tons per unit. These machines are cross-connected so that they can be operated as a pair or independently, providing for adjustment of either machine without interfering with the operation of the other.

The compressor sets themselves are also cross-connected with each other so that in event of the complete failure of either set ammonia can be taken from the other unit, as far as available.

Pump-out lines were installed so that any part of the ammonia system can be thoroughly cleansed without affecting the rest of the system.

Three shell-and-tube type coolers, Fig. 4, were installed for cooling the brine. The brine is pumped to each of the four dehumidifiers (Fig. 5), and there

FIG. 7. PHOTOGRAPH OF BUILDINGS SHOWN IN FIG. 2

sprayed into the mist chamber through which the air is drawn in its passage to the fan. The air is thus brought into intimate contact with the finely divided spray of brine and thereby thoroughly cleansed, reduced to the temperature of the brine and completely saturated with water vapor. The temperature of the air leaving the dehumidifier (and hence its humidity, complete saturation being effected) is controlled by means of a thermostat actuated by the air temperature and acting upon a 3-way valve in the brine circulating pump line. This valve (Fig. 6) is so arranged that it governs the relative volume of brine recirculated from the dehumidifier tank (where the spray is collected

FIG. 8. MAIN SUPPLY DUCT, SHOWING EJECTOR NOZZLES

after falling from the nozzles) and the volume of fresh cold brine direct from the coolers. In this manner the temperature of the brine leaving the sprays is accurately controlled.

Since the operation of the control might add sufficient cold brine to the dehumidifier circuit to flood the tank, means were provided whereby a level regulator operates upon the suction of the circulating pump to equalize the volume of brine being removed from the tank and that being added through the automatic 3-way valve. In this manner the liquid levels in the dehumidifier tanks were maintained within a variation of one-quarter inch.

A large brine storage tank was provided wherein the entire volume of brine in the system can be drained while the dehumidifiers and lines are being cleaned. Operation can then be resumed without the delay incident to making up a new charge of brine.

Brine concentration is maintained by the addition of salt and not by evaporation. The concentrator consists of a small tank placed within the large storage tank. This tank is equipped with tangential jets and so valved that part of the recirculated brine can be by-passed into the jets which are arranged to act against a charge of

FIG. 9. INLET END OF DEHUMIDIFIER, SHOWING COMPRESSED-AIR CONTROLS

salt. The smaller tank overflows into the larger storage tank, providing a simple and effective means for maintaining concentration.

Three Brine Circulating Pumps

Three brine circulating pumps were installed as shown in Fig. 2. Two of these are used for regular operation, the third being a spare, so connected that it can be used for operating the concentrator when desirable, providing a quick concentration.

The length of the brine supply lines is so great that the movement of a maximum volume at certain times sets up a high frictional resistance which varies, of course, from a maximum to practically zero in proportion to the volume of brine being moved. Such a variation in pipe friction would cause a corresponding variation in delivery pressure at the 3-way valves and seriously impair the accuracy of the control. To obviate this variation a special pressure regulator, built by the Taylor Instrument Companies, was installed in the lines, and regulates the delivery pressure at the 3-way control valves between 18 in. and 20 in., with great accuracy.

The thermostatic control which actuates the 3-way brine mixing valve is in operation during the summer season only. Whenever the atmospheric temperature is low enough to provide the necessary cooling, the compressors are shut down and this control is adjusted to operate 3-way mixing dampers, recirculating part of the air from the room, adding the requisite volume of cold air from the outside, and affording a relief for an equal volume through a vertical exhaust tower (Fig. 7). In the summer these dampers are disconnected entirely and the openings closed with heavy tight-fitting doors.

The roofs of the crystallizing rooms are surrounded with a water-tight concrete wall about 10 in. above the roof level. The basin thus formed is filled with water to a depth of about 8 in. The evaporation of this water, in the summer season, absorbs the greater part of the direct sun heat and greatly decreases the loss by radiation.

Air Conditioning

After the air has been conditioned in the dehumidifier it is drawn into large Buffalo Conoidal fans and blown into the crystallizing rooms. The accuracy and sensitiveness of the controls is of little value unless the air distribution within the rooms is uniform and positive. Distribution is effected by means of the Carrier Ejector System, shown in Fig. 8. The circulation is indicated by the arrows in the elevation shown in Fig. 2. The fans discharge into the main trunk duct. From this duct, at regular intervals, nozzles project at right angles. These nozzles are so arranged that the kinetic energy of the high-velocity jet of air is utilized to set up a suction or "ejector effect" which causes a large percentage of the room air to be drawn into circulation. Thus the actual movement of air *within the room* is many times the volume handled by the fans. The path of the circulation, as indicated by the arrows, is across the top of the room, back through the pans, and out through the return duct, which is placed beneath the floor directly under the supply duct, as shown.

This system insures absolutely uniform distribution, and effective and positive velocity, minimum consumption of power at the fans, and enables an apparatus of small capacity to perform work usually requiring much larger, and correspondingly more expensive, equipment.

Accurate Control of Temperature and Humidity of Air of Great Importance

It is essential that the temperature and humidity of the air be controlled with the greatest accuracy, as a drop of a few degrees will begin to crystallize the undesirable sodium salts. From the first day of operation the control was so accurate that no difficulty whatsoever was experienced in holding the variation within a negligible range. All of the thermostatic controls employed act by the expanding and contracting effect of temperature on metal, which effect is utilized to operate a small air valve. The movement of this valve admits or releases an air pressure of approximately 15 lb. per sq.in. which acts upon diaphragm valves or diaphragm motors as required. Fig. 9 shows two of the control panels with small belt-driven air-cooled compressors for maintaining the compression.

It should be remarked that this installation is particularly significant because it again demonstrates the practicability of air conditioning apparatus on a large scale, where dehumidification requires mechanical refrigeration, and where immense areas must be controlled with a precision equal to that of the finest laboratory processes.

New York City.

CONTACT SULPHURIC ACID PLANT, AREA B.

Erection of Huge Sulphuric, Nitric, Mixed Acid and Denitrating Plant Under War Pressure

Construction of One of the Largest Acid Plants in the Country, Under Adverse Conditions—A View of the Situation in General With Methods of Construction

By H. E. and C. E. HOLLISTER

THE construction of one of the largest acid plants of its kind in this country and possibly in the world was started on a river bottom farm, still covered with corn stubble, in March, 1918. The weather was bad—cold and extremely rainy. For a month the sunshine was a rare sight. The frost had just left the ground and a wagon buried to its body was a common sight. A bull team, although perhaps considered by many as out of keeping with modern construction, was a valuable asset and the only certain method of transportation. Corduroy roads had to be built for trucking, plank runways for handling material in wheelbarrows and hand carts, but with all handicaps the wheels were started on an arranged schedule, with a fixed goal, and except for modifications made to suit uncontrollable conditions due to other war requirements of the country, they continued to turn as desired throughout the job.

Acid Plant

The acid plant was a portion of an explosives plant being built for the Government. The trouble in one part was common to the others and all work had to be co-ordinated to avoid undue confusion.

The acid plant covered roughly 110 acres and formed rather a triangular shaped plot, as seen on the general outline plan. The east side was bounded by the main line railroad tracks and a portion of the sorting yard, the west side by the river, while the other sides were boundaries of other areas of the explosives plant. (See Fig. 1 showing general layout of plant. Buildings shown in solid were required first. Each unit as numbered was a complete process in itself and put in operation in succession.)

The contact (sulphuric acid) plant consisted of seven units with capacity of 560 tons of oleum per day, with sulphur storage, building and apparatus for preparing platinum mass, acid storage tanks, etc.

The nitric acid and mixed acid plant consisted of four units with an available capacity of 720 tons per day, with a working storage to hold 20,000 tons of nitrate of soda, and an emergency storage for a surplus of 15,000 tons, also bag washing buildings, storage buildings, etc. The acid mixing plant was arranged to take care of the full output of the nitric plant, with a 30 per cent excess for emergencies. There were offices, service buildings, machine shops, compressor houses, fuel storage and other accessories erected for use of both plants.

In addition to the nitric and sulphuric acid plants, there was erected a denitrating and concentrating plant to handle 480 tons of spent acid from a cotton nitration plant, the concentrated sulphuric being returned to the nitric plant for charging retorts, and the nitric remixed at the denitrating plant with oleum to produce mixed acid.

These figures will give some idea of the size of the plant, but as a matter of comparison it is fair to say that before the war a 10-ton oleum unit was an average size. A fair size plant might have four of these units. This oleum plant had twenty-eight 20-ton units. Ten 6000-lb. nitric retorts were considered a fair sized nitric plant at one time, a few explosives plants possibly having as many as twenty. This plant contained ninety-six retorts arranged for a 7500-lb. charge and could, if the emergency had arisen, have handled an 8000-lb. charge.

The whole plant was much more extensive than any previous construction of similar nature. There were those plants which by slow degrees had grown to great proportions, but even in these there was no group of this size more diversified.

There were many handicaps, which were to be expected on a piece of work of this magnitude, also many which were not expected in advance. Large quantities of material were required, which had to be obtained from sources already crowded with orders, and shipped over congested railroads. Special apparatus had to be built and, due to its nature, could only be obtained from a limited number of manufacturers. Although the plant covered a vast area, storage space was limited, and the receiving and handling of materials had to be closely watched to avoid congestion. Labor and specialized mechanics, that should have been plentiful on a Government proposition at that time, were conspicuous by their absence.

The plans were started in New York and outlined enough for preliminary listing of materials, and purchasing was started. Arrangements were made for delivery of materials on certain dates to correspond as nearly as possible with schedules of construction.

Systems of listing on material bills and item lists were adopted and various parts given mark numbers which were used to distinguish them throughout the preliminary work and for use during construction. Considerable work was done to standardize and simplify the apparatus and buildings for the purpose of ease of construction, economy of materials and to expedite erection. It was necessary in many cases to make changes in design to suit the standards of manufacturers or to make it possible for certain shops to utilize materials in stock. This, of course, cheapened the work and greatly assisted in delivery of finished apparatus.

After designing work had reached a proper point and purchasing had progressed to such an extent that the program of delivery was assured, the construction work was started.

Purchasing

A special department, working in conjunction with the agents for the Government and the director's staff, handled the purchasing for these areas. The engineers and technical advisers, with the advice and assistance of the War Department officers, settled questions of quality and type of apparatus or parts.

An attempt was made to have details prepared and orders placed in advance for materials which would require considerable time for completion, so that all parts would come in as required. Orders were placed on basis of price, quality and delivery, and in some cases prices obtained, especially in castings, were on a par with those made to private industries before the war and high prices of pig iron. It was necessary to be reasonably assured before placing an order that the company was in a position to make the deliveries, and had or was in position to obtain the required raw materials without assistance. With few exceptions, the materials and apparatus were delivered as required.

The preliminary work on all the plant was started as soon as conditions due to the severe winter weather permitted, and actual building of the plant began as soon as the needed material arrived. A temporary spur about a hundred yards from the right of way had been laid and a drive was started for one of the permanent tracks

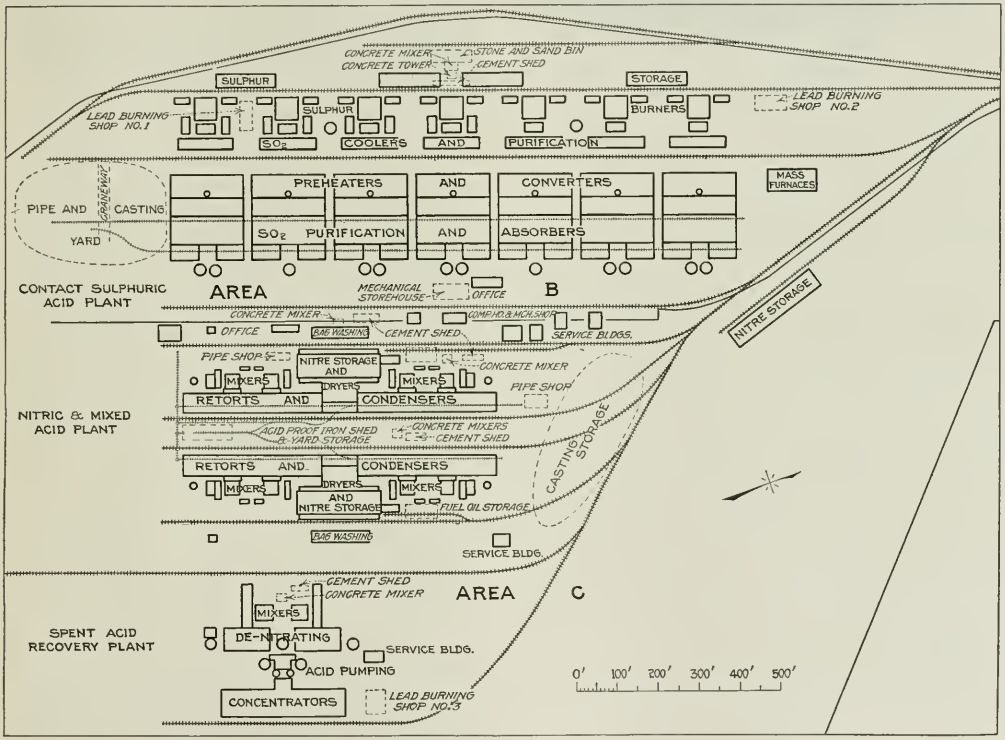

FIG. 1. GENERAL LAYOUT OF THE PLANT

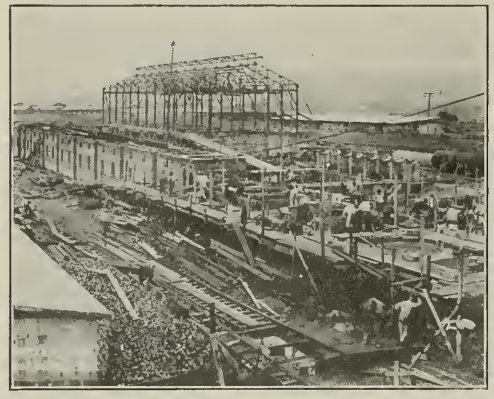

FIG. 2. UNIT 3, AREA C. STEEL WORK OF NITER STOREHOUSE AND RETORT SETTINGS UNDER CONSTRUCTION

through the area. The others were laid as the work progressed.

Lumber and other materials already available were utilized to erect warehouses for construction purposes, offices were erected, which remained as permanent operating offices, but during construction were used for the field office force and draftsmen. Temporary roads, runways, etc., were built and general preparation made for the real construction of the plant. The first excavation was started by hand, and later on steam shovels were utilized where possible. Some forms were also started for the concrete footings.

A large concrete plant with cement storage houses, bins for sand and gravel, and a tower were erected in Area B. This was to supply concrete to Units 2 to 6 by chutes and to the other units by means of concrete buggies. The preliminary starting and early stages of the work were greatly handicapped by the uncertainty of labor, delays in the delivery of some of the construction equipment, and many other annoyances beyond the control of the organization. Housing conditions were at that time insufficient, which caused discontent among the workmen, made worse by the cold weather and rain which fell daily for quite a period. In spite of these conditions a good start was made.

Excavating was done with steam shovels and drag scrapers where possible, and the remainder by hand. Trench diggers were used for pipe line trenches. In most places scrapers were used for back filling in connection with some hand work. In Area B the first unit was excavated mostly by hand, but in other units the greater part was steam shovel work. In this area it was necessary to use dirt excavated from the first four units for building up the grade of the three other units, the ground being highest at the northeast side and sloping toward the southwest.

In Area C footings were excavated through mud in the low ground at Unit 3, and while these were being concreted, scrapers were used to grade land between the two units, the dirt being used as fill west of the unit. After completion of concrete footings, material excavated by steam shovels and scrapers from Unit 1 was used to bring Unit 3 to grade. Excavated material from Unit 2 was also used for back filling in and around Unit 4.

The spent acid plant was on fairly level ground, practically the only excavation being done for the footings. This gave about enough fill for the low spots around the buildings. All the material excavated could be used within a reasonable distance of the point from which it was taken and it was either put in place as excavated, or piled out of the way for distribution later. This was fortunate, as lack of roads made haulage almost impossible. As excavation progressed it was immediately followed by concrete work, which in turn was closely followed by construction of buildings and apparatus.

Concrete Work

Most of the footings were mass concrete. Reinforced concrete was required for some of the walls of buildings and apparatus supports and for storage bins, bag wash houses and trench slabs. Forms were constructed of lumber and made into permanent panels or collapsible forms whenever possible. As many of the footings were duplicates, this saved labor and material and greatly expedited the work.

As many of the walls were high and as it was desirable to fill the whole form at one pouring, the form work had to be well done and carefully tied and braced. No oil or grease was used on forms, but very satisfactory results and a smooth surface were obtained by using finished lumber, and working the concrete well while pouring. Due to the shortage of form lumber, it was sometimes necessary to remove them the morning following the pouring, but care was taken to prevent loading or side pressure from fill to come on the concrete until it was well seasoned, thereby avoiding any injurious results. In most cases after the first units of both Areas B and C were under way, concrete floors were poured at about the same time as footings. By doing this it was not necessary to keep mixers tied up, so preventing interference with other construction. After concrete work in a particular building was completed, the equipment was then available for use elsewhere, and was either used at another point on these areas or turned over to contractors on other areas.

In Area B the first concrete was mixed in small mixers and placed by hand, but later the concrete tower was put into operation and the concrete either shot directly into forms or into hoppers, from which point it was conveyed to the desired locations by buggies. A spur

FIG. 3. COMPLETED STACKS FOR SEVEN H_2SO_4 PLANTS OF WHICH NO. 4 IS UNDER CONSTRUCTION IN THE VIEW

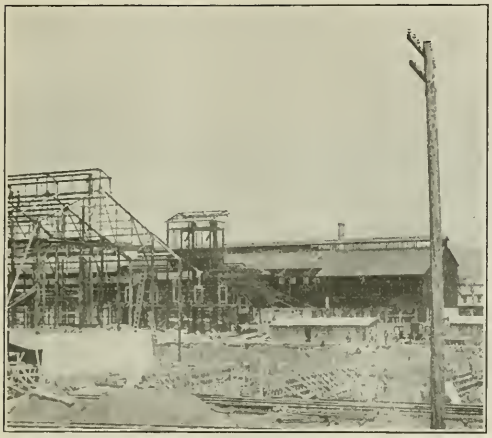

FIG. 4. ELEVATORS, BINS AND DRIERS IN COURSE OF CONSTRUCTION

track was built directly alongside of the material bins as shown in Fig. 2 and material unloaded and delivered to bins by a stiff-leg derrick fitted out with a clamshell bucket. The flow of material from bins to mixer was by gravity. Due to the congestion of buildings and lack of unloading space, the concrete tower was extremely useful and accomplished the desired results. The variation of material and substitution made for sand and stone caused annoyances at the start of the work, but these were overcome as soon as the crew became experienced in handling them. For special mixtures or out of the way places, portable mixers were used.

On Area C the arrangement of buildings made a tower impractical. Austin cube mixers of one-half yard capacity equipped with a self-loading device, filling at ground level, were used. The mixers were cribbed up to such heights that discharge hoppers emptied into a receiving hopper or concrete buggies, and these buggies were pushed along runways above forms. Where possible, mixers were placed alongside of railroad tracks and material used with one handling.

Runways were built up and cleated into sections so that they could be cheaply and quickly changed to any location. These sections were used throughout the job either in elevated positions or on the ground.

Reinforcing rods were cut, bent and otherwise prepared in advance of the concrete work, and were carefully bundled and marked in readiness for use. The steel for the storehouses was prepared in such manner that a section of the building could be assembled in one day. These sections were 50 ft. square and 14 ft. high. Work on the first unit of both Areas B and C was somewhat slow at the start, but rapid progress was made on other units where it was possible to use the forms and standardize the work. The crews were also more familiar with the work than in the beginning.

General Erection

Buildings were constructed with timber, steel and concrete frames, the filling walls being of corrugated asbestos-covered metal, wood covered with roofing paper and battens, tile walls, brick walls and novelty siding. Roofs were of corrugated asbestos-covered metal, wood or cement slabs, with tar and gravel covering. The various illustrations show the types quite plainly. There was considerable delay caused by lack of steel work, its slow delivery being due to manufacturing and transportation conditions throughout the country. Lumber at times ran low, but this construction was most flexible and substitutions could be made which prevented any serious hold-ups of the work. When held up for steel, apparatus was often erected in advance of building. When shortage of any particular materials did occur, the men were immediately shifted to other parts of the job, so that at times work had been started and partly completed at several points. The object was, however, to complete the work in units, as certain buildings were required first to start manufacture. These were indicated and called for in the original schedules and were as shown in Fig. 1. To obtain the greatest efficiency from available workmen, shifting was of course necessary, but they were returned as quickly as possible to the buildings being pushed to completion.

Construction of one unit after another was started in such a manner that the mechanics moved successively from one group to another. This meant that after the first unit was complete and in operation, the successive units were ready at regular periods. Fig. 3 illustrates fairly well units at various stages of completion, each stack being in the center of a unit.

The steel work of the buildings was in many cases also part of the apparatus. It was not always possible or desirable to distinguish between the two for erection purposes. Millwrights, machinists and apparatus erectors were intermingled with other mechanics when and where necessary to properly erect the work, and the work was so laid out and supervised that no confusion resulted. This intermingling of men of various trades required at times considerable tact to keep peace in the family.

Upon completion of the building frame work, and in most cases before the buildings were closed in, erection of apparatus was started. The apparatus in many cases was ready for operation about the same time the buildings were finished. In Fig. 4, center, can be seen elevators, bins and driers in process of erection while building is under way, an example of this type of construction.

The building frame work was simplified as much as possible so as to utilize standard shapes. The steel buildings were fortunately so located that a locomotive crane could be used for placing the steel, in both areas, from railroad tracks. This greatly facilitated erection, especially where it could be unloaded and put directly

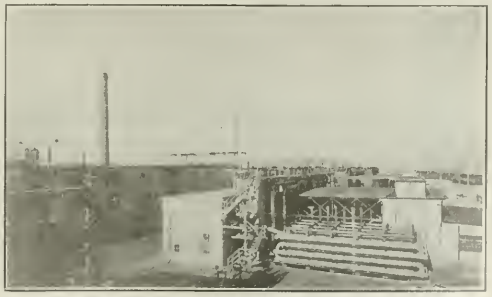

FIG. 5. SULPHUR BURNER BUILDING. SO_2 COOLERS IN FOREGROUND

in place. A narrow-gage track was run from the brick and tile stock piles to buildings under construction and cars either pushed by hand or hauled by an electric storage battery tractor were used to handle the materials. These tracks show in several of the illustrations. Lumber was delivered by cars to the nearest point and distributed by teams.

Apparatus Construction and Erection—Pipe Work

In acid plant work only a small amount of the apparatus can be purchased complete and ready for erection. Most of it consists of material in a partly finished form ready to be built in with other parts to form a certain piece of completed apparatus. Considerable of the apparatus was constructed of masonry with a large amount of lead work, pipe of various kinds and steel work. Mechanics of all kinds were required, and due to the very large scale on which everything was done, it was necessary to train men for many purposes.

Millwrights and machinists were necessary to assemble and erect machines and apparatus which came completed, as well as the building of special apparatus, either by themselves or with other mechanics. Several hundred pipe fitters were required, some on steel and wrought iron piping, which was both flanged and screwed, for handling steam, air, water, acid, oil and other materials. Others were on cast iron pipes which varied in size from two inches to twenty-four inches. These were both flanged and bell and spigot, used to carry illuminating gases, acid gases, acids and water, etc. There was also considerable special pipe and special acid resisting pipe required to handle nitric acid, also brass, glass and special steel pipe.

A pipe yard was located at the north end of Area B. This was the only available open space. Two narrow-gage tracks ran the full length of the sulphuric acid buildings from this yard, and flat cars hauled by electric tractors delivered the material when required. A small overhead craneway with traveling cranes, part of the permanent equipment borrowed from the acid plant, made it possible to reload heavy pipes on the flat cars with little labor. A locomotive crane unloaded the incoming freight cars and placed material in storage piles, as desired. As the freight cars arrived with mostly fixed loads and sometimes with parts not required for immediate use, this method of handling was found very efficient.

At the nitric and spent acid plants in Area C steel

FIG. 6. CONSTRUCTION BUILDINGS. MASS HOUSE TO THE LEFT

FIG. 7. VIEW OF SULPHURIC ACID UNIT

pipe was unloaded for storage as close to the pipe shops as possible. Heavy pipe was delivered direct by locomotive crane to the trenches or places in which it was to be used. Acid-proof iron was included as apparatus and placed in special warehouses.

Lead Work

Lead piping, of which there was a great amount (a good example of which is shown in Fig. 5), was all handled by a crew of about seventy lead burners. Large lead pipes, ells and other fittings were prepared and made up in the lead shops, with all other work which could be handled at this point, leaving the final assembly only for field work. In this way it was possible to utilize the men regardless of weather. The system of narrow-gage tracks made delivery of heavy and bulky parts to their final location an easy matter. The sheet lead as it arrived in carloads was sorted by a locomotive crane and delivered to the proper lead shops. Hydrogen for the burners was both purchased in cylinders and manufactured from spelter and acid on the job. The cylinders were used mostly for assembling lead work in place, as it was more handy and cleaner. Each lead shop was equipped with a very large capacity generator.

The lead burning shops 1 and 3, each located at the most central points, both as to delivery of finished material and railroad facilities, as the handling of the raw materials, as shown by figures given later, was no small part of the job. Lead shop 2, with its storage, scrap melting shed, etc., is seen in the foreground of Fig. 6.

Castings and Apparatus

The heavy castings and parts of apparatus to be erected also required much attention and forethought in handling. A portion of the pipe yard was used for heavy castings and parts of apparatus. The same cranes and industrial cars handled this material. All materials were reinspected before erection, and by the use of the overhead cranes, parts could be handled, sorted and stacked as desired. In this way there was no confusion and a check of stock on hand could be made very quickly.

Tanks were taken from cars and placed directly on foundations as often as possible, with the exception of those to be erected in place. In this case the sheets were taken from cars by cranes and placed as near the permanent location as conditions would permit. As most of the tanks were behind schedule in delivery, all footings were completed in ample time and this portion of the program worked out very successfully.

At Area C, especially in the nitric acid plant, there were many heavy castings. The retorts weighed about

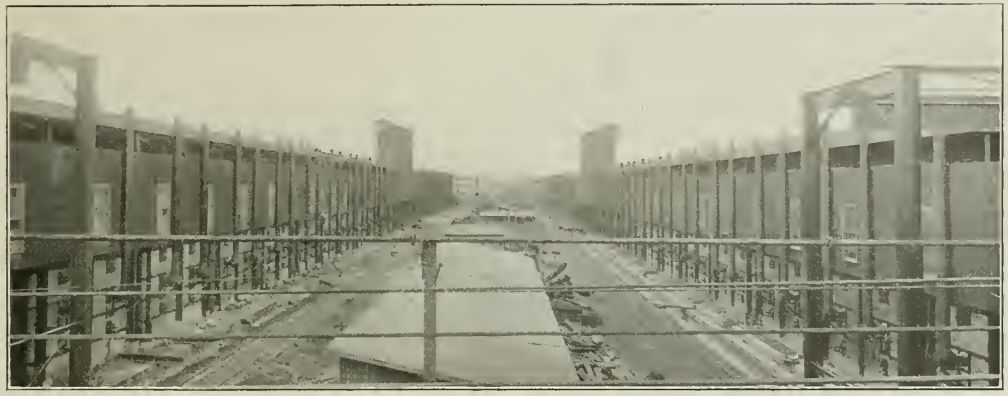

FIG. 8. NITRIC ACID RETORT AND CONDENSER BUILDINGS

eleven tons each. As these came in shipments of two or three, and as it was found more convenient to place them in their settings with a powerful locomotive crane which had to be borrowed, they were accumulated until twenty-four were on hand. The castings as they arrived were unloaded by the regular cranes along the spurs at the south end of the unit and rehandled when enough were on hand. Twenty-four of these retorts as well as their tops could be put in place in six hours. Small castings were sorted, inspected and placed between Units 2 and 4 and taken to location as required by industrial cars.

A warehouse fitted with shelves and bins was erected between Units 1 and 3 at the north end, as shown in the foreground of Fig. 8, where it could be served by two railroad tracks and have wagon delivery. This building was used for the storage of special acid-resisting iron pipe, castings and glass. This material is very brittle and must be handled like glass or porcelain ware. All pieces had to be reinspected upon unloading before being put in stock, as breakage and damage during shipment run high. The warehouse was provided with an industrial track its full length, this track branching out into the four units of the nitric plant. Material was loaded on flat cars as required and distributed. There was practically no breakage of this material after it arrived on the ground, which was considered quite a feat, as in ordinary practice this loss runs very high.

The greater part of the castings for the spent acid plant were unloaded from the cars and delivered by the locomotive crane almost at their destination. Due to the compact formation and nearness of main railroad tracks, an industrial track system was not used. In the other areas they were indispensable and saved much time, labor and trouble.

The apparatus was assembled and erected inside of the buildings by chain blocks and hand derricks. In some parts of the sulphuric and spent acid plants, where continuous replacement of heavy castings is necessary during operation for the purpose of cleaning or replacing apparatus, permanent craneways were erected. These were used for erection purposes during the period of construction.

Mason Work

A great amount of the work, as is usual in acid plants, consisted of masonry. This also varied from common wall and fire-brick settings to acid-tight masonry. Even the acid-proof masonry consisted of various grades of acid-proof brick laid in a number of mixtures of acid-proof cement to suit the various conditions. Fire brick was also of several qualities to meet the heat requirements. Brick work in plants of this nature must be

FIG. 9. TOWER AND PREHEATER BUILDINGS. BRIDGES CARRY LEAD SO_2 LINES

FIG. 10. NITRIC AND SPENT ACID PLANTS

properly and carefully constructed. The life of the plant and economy of operation in many cases depend on the proper carrying out of this end of the work. Many masons are not suited and others without the proper experience must be trained for their particular work. Where possible and practical, mortar was mixed in small concrete mixers, the large number of masons and extent of work making this an economical method. Where parts of the building or other apparatus were built into the masonry, various mechanics worked together or shifted their work to accommodate one another.

Inclines were constructed, operated by gasoline hoists, equipped with narrow gage cars to supply material to towers and other high places. One is shown in center of Fig. 6 at the left of locomotive crane. These were so arranged that a number of towers could be fed from the same incline. Fig 7 is a view of one unit of the sulphuric plant looking west. The nitric and spent acid plant is in the distance. The river is to the foot of the hill in the background, almost half a mile from the camera. Fig. 9 shows a view looking south between the sulphuric buildings. The building to the right, containing furnaces, had to be of steel. The small one at the left is timber, that to the far left is of steel and houses the sulphur burners.

Fig. 10 shows a view of one end of the nitric acid plant with pipe trestle, pump houses, etc., for all acids pumped to the explosive plant. Fig. 11 is the denitrating end of the spent acid. The concentrating plant can just be seen in the distance to the right.

There were used in the construction of these plants roughly speaking 2,000,000 common brick, 110,000 stack brick, 2,000,000 fire brick, 1,500,000 acid brick and 6,000,000 ft. of lumber, 500,000 building tile, 38,000 yd. of concrete, 120 tons of reinforcing rods, 3000 tons of fabricated structural steel, 40,000 ft. of steel and wrought iron pipe, 6000 ft. of cast iron pipe, 8900 tons of special iron castings, 1750 tons of sheet lead, 1314 tons of steel tanks and 715 tons of acid-resisting iron castings.

There was also used 4760 hp. of motors, 158 pumps of cast iron, steel and special acid-resisting iron, 28 low pressure blowers of 2000-ft. capacity each, and considerable quantities of miscellaneous material, among which was 1000 tons of coke, 90 tons of mineral wool, 3700 tons of rock quartz, 128 sets of recording pyrometers, and many miscellaneous articles. There was an average of 20 cars per day to be unloaded and distributed, in addition to which large quantities of all kinds of material were delivered by truck.

The acid plants were built and organization furnished by the Leonard Engineering Co. of New York and Chicago, of which Mr. H. E. Hollister was consulting chemical engineer and technical superintendent. Mr. C. E. Hollister was superintendent in charge of transportation and materials. Mr. W. M. Kallasch was manager.

The Ordnance Department officers in charge of the operation deserve unlimited credit and thanks for their hearty co-operation and assistance. It was through their untiring efforts that many a delay was avoided.

FIG. 11. SPENT ACID PLANT. DENITRATING TOWERS IN THE FOREGROUND

Electrochemistry in Its Human Relations

Electrochemistry Can Contribute to Human Progress and Raise the Standard of Living by Providing Cheap Fertilizer for Increased Crop Yields—It Can Improve Sanitation and Produce New Materials of Construction

By F. J. TONE*

DURING recent years it has been a custom which has now more or less become a dictum that the annual address of the president shall treat of some of the broader aspects of electrochemistry. We have in turn had discourses on the æsthetics of electrochemistry, its external activities, its economic forces, and its public relations. I need offer no apology, therefore, in starting out this morning to make some observations on electrochemistry in its human relations. We are human beings as well as electrochemists, and we may well study the relations of our science to the world problems of today and how we can give most immediate and most effective service for the betterment of human society.

For four years we have been in the thralldom of a great war. We have been passing through a period of violent evolution, the nature and extent of which we have hardly begun to measure or realize. Science and industry, and in fact every human activity, emerges from this world turmoil with new and rapidly shifting viewpoints and new responsibilities, and electrochemistry forms no exception. It is, therefore, profitable at this time to take some survey of our present situation and to forecast our future activities and responsibilities in the new alignment of human relationships. If a new era has begun, what is our part in it?

Big Results of the War

I shall not try to outline any "fourteen points" of future social progress or to say whether some of our values by which we measure such progress are true or false, but one or two things can be stated with a fair degree of assurance. As one of the big results of the war new and better conditions of living are demanded by the masses of the people in all countries. If a higher plane of living in the matter of food, clothing, housing, fuel and sanitation is to be established, and if shorter hours of labor and more opportunity for recreation and self-improvement are to be the order of the new day, this can only be bought about by vastly increasing the production of all the essentials which enter into the needs of modern society. Not forgetting such factors as co-operation, efficiency of organization and distribution and elimination of wastes, production can be increased principally in two ways, first, by using labor more efficiently, and, second, by further supplementing and supplanting labor by the chemical and mechanical instrumentalities of industry. Either we must get more out of labor or we must stimulate the discoveries that will make labor more productive than before. If the world is going to work less, science must work more. The work of the world cannot be done in a six-hour day and a thirty-two-hour week unless applied science gets in a lot of time-and-a-half on week days and double-time on Sundays.

Among the problems of first importance is that of the world's food supply. The crop yields of the world must be vastly increased, and this in the face of a decreasing labor supply. If cereals, cotton and animal fodder must be produced in greater quantity and more cheaply, the answer can only be found in improved transportation and traction for the farmer and in a vastly extended use of fertilizer, and here rests a big problem with the electrochemist.

Judged by European standards, the American farmer is inefficient. He produces fourteen bushels of wheat to the acre, while in Europe the same acre yields thirty. European yields all along the line average from 50 to 100 per cent greater than American yields, and while this increase is in part due to intensive farming, better selection of seed and crop rotation, the big difference is in the enormously greater use of fertilizer. It is of the highest economic importance that the American farmer shall use more fertilizer.

The Electrochemist's Part

The three main elements of plant food are nitrogen, potash and phosphoric acid, and each one of these carries a problem for the electrochemist. The fixation of nitrogen is one of the great triumphs of electrochemistry and the possible exhaustion of the natural nitrate fields is to us no longer a matter of any anxiety. So long as we have energy and air the land need never want for ammonia. Still, the efficiency of the arc process of fixing nitrogen is today less than 5 per cent, and between this figure and the best efficiency attainable, there is certainly breathing space for the most energetic of our research workers. The extension of the cyanamide process has been one of the remarkable chemical events of the war. Its opportunity for peacetime accomplishment is no less, but we still have some distance to go before artificial nitrates can be laid down to the farmer in such quantity and at such price as will mean the doubling of our crop yield.

The Potash Question

The potash problem during the war has been brought into the field of electrochemistry. The Cottrell system of electrostatic precipitation has been successfully applied to blast-furnaces and cement plants, and if all the waste gases from such plants were treated by the Cottrell process, the possible recovery of potash is equal to our pre-war consumption. We can hardly hope that this is commercially possible, but in many localities it will give a permanent source of potash which will maintain its existence under competitive conditions. What the electric furnace can do in phosphoric acid recovery

*Presidential address delivered at the 35th general meeting of the American Electrochemical Society in New York City, April 3, 1919.

is not so well proven. But passing over this, we see that the solution of our national food problem is one in which, despite our past accomplishments, we still have large responsibilities.

In the new order of things we are going to banish the slums and have more healthful living conditions, and the rôle of the electrochemist in sanitation is told in the story of chlorine. We learn that when the armistice was signed we were just ready to deliver each day to our fighting forces on the western front over 200 tons of poison gas. The basis of this great offensive weapon was chlorine, and it was denied its opportunity to demonstrate in a big way what it could do to win the war against the Huns, but I believe it has a far greater opportunity in the germ warfare of peace times.

Chlorine in Sanitation

In starting to investigate the work that chlorine is doing in sanitation, I knew in a general way that it was of growing importance in the purification of drinking water, but upon assembling all the data it was astounding to find that chlorine is today making safe the drinking water of more than 20,000,000 people of this country who dwell in cities. Chlorine is safeguarding one-fifth of our population from typhoid. We learn that a military force or an industrial expedition can go anywhere in the tropics and be at all times assured of potable water if it carries a few pounds of hypochlorite. In the Carrel-Dakin solution for the treatment of wounds, the use of chlorine is defined by a recent authority as the greatest discovery of surgery in the whole war. During the recent epidemic of influenza the number of cases in the cell rooms of two electrolytic chlorine plants located in different States was one-half of that in any other portion of the plants. Starting with a few such facts as these, what more is needed to build up a great structure of organized sanitation with chlorine as its basis? We are looking for an outlet today for a huge producing capacity brought about by the demands of the war. Do not these examples of what chlorine is doing in germ warfare clearly point the way?

Sterilization of Sewage

The sterilization of sewage is as logical a measure of sanitation as the sterilization of drinking water. To be sure, no city drinks its own sewage, but some other city generally does. Why permit Chicago and Milwaukee, Detroit and Cleveland to pollute the waters of Lake Erie, Lake Ontario and the St. Lawrence? Why should Pittsburgh pass its germ-laden water on to Cincinnati and Louisville when an adequate remedy is available at reasonable cost? One hundred and twenty pounds of hypochlorite will sterilize 1,000,000 gal. of screened sewage. A city of 1,000,000 inhabitants can sterilize its sewage at a cost for its chemicals of $360 per day. The cost for a single inhabitant for one year would be about twelve cents.

But the work of chlorine does not stop with water supply and sewage. It should be used to flush and sprinkle our streets, to clean our cars and public buildings and to sterilize our dairies. The organized use of chlorine in sanitary milk production will do more to give our children a pure milk supply than any possible system of inspection.

We are searching for an outlet for our excess chlorine in metallurgy and in organic chemicals. If our electrolytic chlorine friends would begin telling people how they can live in a prophylatic environment, how they can feed their babies pure milk and how they can avoid poisoning their neighbors who live lower down on the same watershed, conditions in the chlorine market would soon be such that they would no longer worry about what the Government is going to do with Edgewood.

Super-Steel

Again, in the metallurgy of steel, if electrochemistry has made great contributions to the art, its responsibilities are no less clearly defined. No one now doubts that we shall soon attain to the super-steel and it is no less clearly indicated that this will be accomplished by the electric steel furnace and electrically produced alloys.

The triplex process using the electric furnace as the third step for the refining operation produces a steel of crucible quality at a cost of a few dollars a ton more than open hearth steel. When it is understood that such steel produces rails which do not break and plates which do not fracture, it will require no advertising campaign in the popular weeklies to bring this product into universal use. Public opinion will demand it.

The alloy steels have made possible the modern automobile, the aëroplane engine and the farm tractor motor. Alloy steels have been a luxury. They have been used only in the vital parts of the mechanism where enormous strains must be met with a minimum weight of material, but their use must be extended. High quality is not incompatible with tonnage. It is the work of the electrochemist to make possible their use as common materials of engineering, thus contributing vastly to improvements in transportation and the mechanical arts. No one needs to have pointed out what this signifies as an economic gain in modern life.

But the field of alloy steels has by no means been fully exploited. The results which the steel maker has achieved with tungsten, molybdenum, chromium and vanadium, marvelous as they are, by no means mark the limit of the art. We now seem to be on the eve of still more important advances based on the use of new alloys including ferro-uranium and ferrozirconium. We hear whispers about a zirconium steel of 300,000 lb. tensile strength and 30 per cent elongation. Not being a steel maker and having no metallurgical reputation to lose, I may venture in my imagination to build an ocean liner or a freight train of this super-steel in which the dead weight is cut in half and the carrying capacity is increased 25 per cent; or, may I visualize the super-steel bridge and finally the super-steel Pullman car, but, in the latter case, we are not so anxious to reduce the weight of the car and save steel. Rather we will make the super-steel Pullman four times as strong with the same weight of steel, and then sleep soundly in the rear section of the rear car while the second section of the train follows one short block behind. Briefly stated, the job of the electrometallurgist is to put super-steel on a big tonnage basis.

Let us now consider energy resources. These are fuel and water power, and their proper utilization not only will reduce the sum total of human toil necessary to run our industrial machine, but is a measure of vital importance to coming generations. Our energy resources are necessary to the functioning of every other resource. They are at the very basis of industrialism, transportation and domestic well-being. Thus they con-

cern society broadly, but they peculiarly concern the electrochemist because cheap electric power is a basic element in electrochemical production. The electrochemist was responsible for the success of the world's first great hydro-electric development at Niagara and became the natural champion of the utilization of our water power resources. But why have we failed to sell this proposition to the man in the street and to those whom in his wisdom he has chosen to legislate for him? There may be many reasons for public indifference to coal economics and the waste of water power, but the fact remains that we have as yet failed to state the simple facts and principles of our energy economics in a way which carries conviction to the people with whom responsibility for action lies. Here are some of them:

1. Coal is our greatest energy resource. It is irreplaceable and notwithstanding an apparent popular belief to the contrary, it is not inexhaustible. The amount available for present and future generations is known to be very definitely limited. The curve of consumption is rising regularly and rapidly and we can compute with a fair degree of accuracy when our magnificent coal reserves will be exhausted.
2. Coal is wastefully mined, wastefully transported and wastefully utilized. If the bituminous coal used for domestic heating alone was first converted into artificial anthracite and the by-products recovered, it would represent a saving of more than twice our entire output of gold for 1917. If our railroads were electrified and fed from central stations recovering the by-products, this saving would be doubled.
3. Fuel and water power are practically interchangeable in industrial economics. The failure to use water power is just as truly a waste as would be the burning of our coal mines and oil wells. If Congress were to enact legislation to set the torch to one-third of all of our coal that was mined in the country last year, it would be no greater an act of folly or a crime than to obstruct water-power development. The utilization of water-power resources will save coal and oil for future generations and release for other useful work in the present generation hundreds of thousands of miners, vast transportation facilities and thousands of railway workers.

Legislation Suggested

Having convinced the people that water power must be developed, perhaps the most difficult part of the problem remains to be solved, which is to arrive at a form of legislation in which the people and the capitalist believe that their respective interests are protected. Passing over the question of Government ownership of water powers, I believe we must all now agree that no legislation for private development stands any chance of enactment which does not carry with it a very much larger measure of public control than would have been acceptable a few years or even a few months ago. Political ideas have changed, and one can plainly observe that public sentiment will not again consent to the development of its water powers as an unrestricted private monopoly. It would not so consent even when awakened to the great economic crime of letting them run to waste. After all, what we want is the power and I believe this Society can not do less than endorse legislation in which public interests are fully protected by control of rates and proper limitation of charter rights. Following this we want Government surveys covering our complete energy resources and their utilization.

My conclusion shall be brief. It is plain that our science faces some of the big human problems of the day. Our opportunity for service was never greater, and I believe it will not be passed by.

Salvaging Industrial Casualties

By Douglas C. McMurtrie

Director Red Cross Institute for Crippled and Disabled Men, Twenty-third Street and Broadway, New York City

In the past, our method of dealing with men permanently disabled in the course of employment has been to pay the worker a pension in the form of compensation, and forget him and his injury. But the cost of disability in the metal trade has not been alone in the premiums paid for casualty insurance. There has been the cost involved in the training, experience and adaptation of a skilled worker who does not return to his job, and the fitting of a newcomer to take his place.

There are three means of reducing and approaching the complete elimination of the cost of disability: first, accident prevention; second, thorough medical attention to minimize the disability resulting from the injury, and third, salvage of the remaining abilities of the worker through rehabilitation for self-support. The first of these has already received wide attention from employers and has wisely been encouraged in a financial way by casualty insurance companies and State funds. The values of the two latter have, however, not as yet been appreciated. Their energetic application would effect a tremendous saving to industry.

Insufficient Medical Treatment

Many injuries from which men would completely recover in a short time under adequate and high-grade medical attention are treated for an insufficient time, or by incompetent physicians, and, instead of a prompt return to work, the case at best drags along over an extended period and at worst becomes chronic or develops into permanent disability. Some States require the insurance carrier to provide but two weeks of compulsory free medical attention to the injured man. For the insurance company to take advantage of this limitation is the most short-sighted policy possible, because for every dollar saved in physicians' or hospital fees, the insurance carrier pays out later ten dollars in compensation. And what the insurance company pays is actually paid by the insuring employers in their regular premiums.

Unlimited medical attention of the highest grade should be an axiom of casualty practice. It should be insisted upon by employer and workman alike. The best outcome of any injury is to have the employee return to his job a well man in the shortest possible time. It is well to develop a science of dealing with cripples, but the ideal is to have fewer and fewer cripples with which to deal.

Rehabilitation for Self-Support

The third method of attack on the cost of disability is rehabilitation for self-support—the re-education of an injured man for an occupation which he can follow, or a process which he can perform, in spite of his handicap. The science of rehabilitation is new, and the experience in it has practically all been gained in the effort to make sound and just provision for the disabled soldier or sailor. Every country among the recent belligerents is to-day operating a comprehensive system of re-education for disabled soldiers, and is placing upon that system more dependence than upon the pension system.

Paying a man a small monthly or weekly stipend on which he is expected to live in idleness is not a very constructive method. With the breakdown of confidence

in the pension system, it was realized that the only real compensation for disablement was restoration of capacity for self-support. It was further realized that very few jobs require all the physical faculties and that in the present-day variety of industrial processes it is possible to find a job in which a man with a given type of disability can function 100 per cent efficient. Some jobs are standing, some seated, others require walking about; some jobs at a bench working on small articles require but little strength, others involve great physical exertion. Still others do not require the sense of hearing; in others the sense of sight is not essential. Finding the future work of the disabled man, therefore, requires expert and painstaking choice, but a successful selection is possible even for the seriously handicapped. The first aim is to place the man back in a different job in his own trade or in a trade closely related. In such a job his past experience will stand him in good stead. Failing this, he can be re-trained for a different line.

Schools for Crippled Men

The process of re-training the disabled is known as re-education, and can best be provided in a special school for crippled men. The first school of this kind in the United States is the Red Cross Institute for Crippled and Disabled Men, established in New York City through the generosity of Jeremiah Milbank. At this school, open to disabled civilians and soldiers alike, six trades are already being taught: artificial limb making, motion picture operating, oxy-acetylene welding, printing, jewelry work, and mechanical drafting. More will be added as the demand develops. Graduates are already giving satisfaction in the jobs to which they have been graduated, so the enterprise has passed the experimental stage. And in the results attained with disabled soldiers abroad there is overwhelming evidence of the logic and practicality of rehabilitation.

The cost of soldier rehabilitation is being met by the United States Government and by the Governments of some of our allies. It will be admitted without argument as desirable that the advantages of re-education be made available to disabled civilians as well, but will not the cost be prohibitive? The fact is that rehabilitation effects a reduction rather than an increase in the cost of disability to industry or to the community as a whole.

A Typical Case

A typical case will illustrate how the saving is effected. A worker in Massachusetts was injured by a fall while working inside a submarine and his hand became permanently crippled. In due course his compensation rate was determined and he was referred to the insurance carrier to be paid $10 a week for a long period, with a maximum total payment of $4000. Since the disability was manifestly permanent, the insurance company wrote the case off its books as a $4000 loss and transferred that amount to reserve to cover the weekly payments. After the compensation had been paid for nearly a year, a new official of the insurance company began looking over the list of men to whom the company was paying compensation. His attention was directed to the man in question and the latter was requested to call at the office of the company. The case was, like many thousands of others, susceptible of rehabilitation for self-support, so the insurance company official put a proposition to the man in very frank terms. "I believe that you can be trained to earn a good living. I want you to understand very clearly, however, that this proposal is to the financial advantage of the company, but I also believe it is to your advantage as well. A total income of $10 a week is not very attractive to you and you would probably rather return to work at a good wage than remain idle. If you will consent, the company will send you to a school of re-education and see if we cannot get you back on your feet in good shape."

The injured man consented to the proposal and the company sent him to the Red Cross Institute in New York. They began to pay him not $10 a week, as required by law, but $40 a week, $20 to him in New York and $20 to his wife at home. The company also paid his traveling expenses in both directions. In eight weeks he was re-educated in oxy-acetylene cutting and welding and returned home. He is now making not only a satisfactory wage but twice as much as he had ever earned before the accident took place.

Every Party in Interest Benefited

In the whole transaction every party in interest was benefited. The man was advantaged in that his general living standard was distinctly raised, and the necessity of working for his living could not be considered as a hardship. The company paid less than $500 for his rehabilitation, and this expense, in conjunction with the $500 already paid in weekly compensation during the first year of idleness, made a total for the case of $1000. It was thus enabled to credit $3000 profit to the account of profit and loss. The community was infinitely the gainer in that the man, formerly an unproductive consumer, became a useful producer instead. The community further gained in the elimination of the disabled man from the category of a prospective dependent, because while compensation might have taken care of him in a very insufficient way during the period of idleness, there would have come a time when compensation ceased and then he would have been in a desperate economic status indeed—confirmed in habits of idleness, untrained for skilled work, and without any source of support.

Revision of Compensation Laws Needed

A more intelligent handling of disability by insurance carriers will, therefore, reduce their expense, and will thus cut the cost of casualty protection to the employer. There is needed also, however, some revision of compensation laws so that there may be definite encouragement to insurance carriers to offer opportunity of rehabilitation and definite encouragement to the disabled men to take advantage of it. Practically every compensation case that has ever come to the Red Cross Institute has come on the day his compensation expired. For one year, for two years, or for four years the man has existed in idleness, drawing compensation, and cultivating habits of indolence. When his support was cut off, he then became interested in re-habilitation. Present compensation legislation tends to encourage the man to remain idle because his payments are reduced by any improvement in earning capacity. A revision of this practice will make for more constructive provision.

In short, the first effort should be to prevent injury, the second to minimize its permanent effects, the third—when disability has ensued—to offset its economic consequences. The execution of this complete program is not only sound humanitarian practice—it is good business as well.

Effect of Certain Accelerators Upon the Properties of Vulcanized Rubber

Experimental Data on the Activity of Certain Organic and Inorganic Accelerators—Magnesia in Small Amount Is Less Active Than Certain Organic Accelerators, and Does Not Impart to the Mixtures the Physical Improvement Characteristic of the Latter

By G. D. KRATZ and A. H. FLOWER*

THE relative accelerating effect of inorganic and organic accelerators has been subject to a diversity of opinion ever since the latter have been employed in technical practice. Likewise, the effect of each upon the quality and physical properties of the vulcanized rubber has been a matter of discussion.

The results recorded in the experimental part of this paper were obtained in the course of several investigations carried on for the joint purpose of determining the relative activity of certain inorganic and organic accelerators, and the permissibility in the use of the sulphur coefficient in evaluating samples of vulcanized rubber known to contain accelerators. As recorded here, this has consisted primarily in (*a*) a comparison of the relative effects of heavy calcined magnesia and an (unidentified) organic accelerator in a mixture containing only rubber and sulphur, and (*b*) a comparison of the effect of larger amounts of heavy calcined magnesia, light magnesia and lime in a mixture which contained an excess of zinc oxide.

Irrespective of the effect of accelerators upon the physical properties of the vulcanized mixture, possibly the advantage most often claimed for the organic variety in preference to inorganic substances is that, in accelerating vulcanization, the former are much more active than the latter and can be used in small amount to replace much larger quantities of litharge, magnesia or lime. Incidentally, the use of heavily pigmented mixtures is avoided by this substitution. Van Heurn[1] and many others[2] have given figures subject to this interpretation. In a recent communication, however, H. P. Stevens[3] has taken exception to this view, and, further, has obtained results which show that magnesia is more powerful than the inorganic accelerator litharge, or even the organic accelerator isonitroso-dimethyl-aniline. While Van Heurn has also given figures for vulcanization coefficients which show that magnesia is more powerful than litharge, unlike Stevens, he found one-fourth of 1 per cent of p-nitroso-dimethyl-aniline to be more active than even 1 per cent of magnesia.

General Part

Although our investigations have not included a comparison of the relative effects of magnesia and p-nitroso-dimethyl-aniline, the organic accelerator which we employed in place of the latter substance was found to be far more active, when used in small amounts, than were similar quantities of magnesia. Likewise, the physical properties of the mixtures which contained the organic accelerator were shown to be superior to those obtained with similar amounts of magnesia. This, however, did not at first appear to be the case owing to discrepancies found to exist when the load required to effect a given extension is taken as a measure of the physical properties[4]. In this instance then, the sulphur coefficient may be said to afford a fair index of the state of cure, as measured by the physical properties, of mixtures known to contain small amounts of either inorganic or organic accelerators.

This statement, however, was not found to be of general application, and certainly is not true for mixtures which contain larger amounts of inorganic accelerators in the presence of an excess of zinc oxide. We have never regarded zinc oxide itself in the same manner as Van Heurn[5], who found it to act as a retardent of the vulcanization reaction. Nor have we, with King[6], classed it, strictly speaking, as an accelerator. Our experience has been more similar to that of Ditmar and Theiben[7], who found that large amounts of zinc oxide effected a slight, and limited, increase in the rate of vulcanization (sulphur coefficient).

On the other hand, contrary to what might be expected, we have found that mixtures which contained fairly large quantities of both magnesia and zinc oxide, when vulcanized to maximum physical properties, had lower sulphur coefficients than a control mixture which was vulcanized to the same degree without the assistance of an accelerator. The substitution of lime for magnesia in such a mixture, however, was found to produce quite a different effect. With lime, after an initial decrease in the sulphur coefficient, the latter value was found to respond to a further increase in the amount of accelerator. This difference in the action of the two substances would indicate that their function in the mixture is not identical.

Our results with heavy mineralized mixtures have shown that such mixtures are not only subject to misinterpretation, but also that (as has already been stated by Eaton and Grantham[8]) the constituents of the mixtures tend to obscure or mask the individual properties of the rubber used. With this the case any formula, such as proposed by Dannerth and Gage[9], is untenable for the valuation of raw rubbers.

Fundamentally, the purpose of any ordinary vulcanization is to obtain the maximum physical properties which the mixture will retain unimpaired over the longest period of time under the conditions to which it will be subjected. Our experience in the past has been that this physical condition may be largely independent of the sulphur coefficient, particularly if the mixture has been vulcanized with the assistance of an accelerator. Generally speaking, we have not found that the sulphur coefficient affords a reliable indication of the physical properties of a vulcanized rubber mix-

*Read before the New Jersey Chemical Society, Jan. 13, 1919.

ture or that it can be taken as a measure of the state of cure except possibly in the case of mixtures which consist of rubber and sulphur only. We agree with Stevens[10], however, that for *hevea* rubber practically all mixtures with a sulphur coefficient in excess of 3.2 will be subject to rapid deterioration.

In a former paper[11] we have given the limits for the vulcanization coefficient of *hevea* rubber at 1.7 to 2.8. Under standardized conditions, the higher figure has been found to be consistently approximated by mixtures vulcanized without the aid of an added accelerator, or with the assistance of one which is only mildly active. The lower figure has been found to apply for mixtures vulcanized with the assistance of even small amounts of powerful organic accelerators or larger amounts of magnesia. The anomaly found to exist between the action of magnesia and lime, however, indicates that a certain amount of reservation should be made in interpreting the coefficients of mixtures which contain either of these substances.

In view of our results as a whole, while we agree with Stevens[12] that the sulphur coefficient is most important as an indication of the ultimate stability of the product, in general practice it should be considered as an indication only. Even in the case of mixtures composed solely of rubber and sulphur we have found it dangerous to evaluate between them on the strength of their sulphur coefficients alone, unless the past histories of the samples in question are definitely known. As Stevens[13] has stated in a subsequent communication, the true value of a product, as expressed by its state of cure, is obtained from physical and chemical tests only when they have been made after a definite period of aging conducted under carefully standardized conditions. Our results along these lines will be reported upon in the near future.

Experimental Part

As a considerable portion of the work described in this part was carried on prior to our repetition of Stevens' experiments, the same sample of rubber could not be used throughout. However, the same sample of rubber was employed for all of the mixtures in each of our experiments.

The rubber used was good quality, thin pale first latex (*hevea*) crêpe. In each instance the sample was subjected to the minimum amount of milling necessary to work in all of the ingredients. Where small quantities of accelerators were used the total time of each mixture on the mill was 18 to 20 minutes[14]; with the mixtures which contained larger amounts of accelerators and zinc oxide this time was increased to 22 to 25 minutes. All mineral substances were previously sieved through a 100-mesh screen.

The heavy calcined magnesia was previously ignited and found to contain 92.73 per cent MgO. Specific gravity 3.24.

The extra light magnesia gave a loss of 4.0 per cent on ignition, after which it was found to contain 94.0 per cent MgO. Specific gravity 2.82.

The lime was air slaked, gave a loss on ignition of 13.46 per cent and contained 55.12 per cent $Ca(OH)_2$. Specific gravity 2.19.

The zinc oxide was lead free. Specific gravity 5.64.

Accelerator "A" was prepared by the condensation of an amine with formaldehyde. It was of C. P. quality.

In all instances, after mixing, a rest period of 24 hours was allowed before vulcanization. A recovery period of 7 days was then permitted before physical tests or sulphur estimations were made. The combined sulphur was estimated by the method of Rosenstein-Davies[15]: the samples, having first been subjected to 24 hours continuous extraction with acetone in a Soxhlet apparatus, were dried in air and then in vacuo at 100 deg. C. to constant weight. The sulphur coefficients given represent the combined sulphur of vulcanization expressed as a percentage of the rubber in the mixture.

$$\text{Sulphur coefficient} = \frac{\text{per cent combined sulphur in the mixture}}{\text{per cent rubber in the mixture}}$$

The physical properties of the mixtures which contained small amounts (0.10 to 1.25 per cent) of accelerators were measured by the method employed by Stevens, *i.e.*, measurement of the load required to effect an extension of one to nine, and also at break for tensile strength and percentage elongation. In making this comparison, figures for both methods were obtained on the same sample or test piece by recording the load required to effect the given extension and then increasing the load and continuing the extension to breaking point. Each figure given in the following tables is the average of at least three test pieces.

Irrespective of the adaptability of the two methods as a means of testing samples of different mixtures, both of them are subject to criticism. The measurement of the load required to effect an extension of one to nine was unsatisfactory in that even small amounts of magnesia decreased the percentage elongation to such an extent that this extension was made just short of the point of rupture, or break. The danger of misinterpreting the results obtained by this method, due to this feature, is commented upon elsewhere in this article. This method would be more generally applicable if the load required to effect a lesser extension was recorded. On the other hand, when tested at break, the samples which contained but small amounts of accelerators had a tendency to be cut by the clamp holding the test piece, before the point of rupture was reached.

Note: The mixtures which contained zinc oxide were tested at break only. All results were obtained on a Scott testing machine of the vertical type.

Experiment 1

In this experiment we first followed the plan outlined by Stevens and have compared the accelerating effect of magnesia against an organic accelerator which we have called Accelerator "A." The effect of these accelerators was tested in the same mixture as previously employed by Stevens, namely, 90 parts of rubber and 10 parts of sulphur[16], with added amounts of the accelerators varying from 0.10 to 1.25 per cent on the rubber content. Vulcanization was carried on in a platen press for 60 minutes at 35 lb. steam pressure (281 deg. F.), after which sulphur estimations and measurements of the physical properties were made on the vulcanized products in the manner previously described.

We found the vulcanization coefficients of the series actuated by our "Organic Accelerator A" to be uniformly higher than those obtained with similar amounts of magnesia. (Col. 3, Tab. I, and Fig. 1). This difference between the results obtained by Stevens and us is readily accounted for in the selection of the organic accelerators employed. His accelerator, as well as our own, is unidentified. When the physical properties of

our two series of mixtures were expressed in the manner adopted by Stevens, that is, by the measurement of the load required to effect an extension of 1 to 9, Accelerator "A" was found to have a slight advantage up to about 0.5 per cent, at which point magnesia produced superior results. (Col. 4, Tab. I, and Fig. 1A.) Thus, the physical properties of the series which contained Accelerator "A" are seen to be at variance with what would be expected from their respective sulphur coefficients, provided that the latter figures can be taken as an indication of the state of cure, as measured by the physical properties.

As the series which contained Accelerator "A" appeared to be much superior to the corresponding mixtures containing magnesia, when judged by the "thumb and tooth," it was felt that the physical properties of the two series were not fully expressed by the above method. They were then expressed in terms of the tensile strength and percentage elongation at break.

When interpreted in light of these results (Cols. 5 and 6, Table I, and Fig. 1A), an entirely different relation was seen to exist. Even in this instance, however, it cannot be said that a direct relationship exists between the sulphur coefficients and physical properties of the various mixtures. In the cases of the mixtures vulcanized with the assistance of Accelerator "A," it is evident from the figures obtained for the percentage elongation at break that this property increased coincidentally with an increase in the tensile strength"; with magnesia, on the contrary, the tensile strength was increased at the expense of the elongation.

This difference in the effect produced in the percentage elongation by small amounts of accelerators prohibits the use of the load required to effect a given extension as a measure of the physical properties of the two series of mixtures. As the percentage elongation of a mixture is increased, by the action of an organic accelerator or otherwise, unless this is accompanied by a corresponding and uniform increase in the tensile strength, a given extension will be effected by a lesser load than would normally be required. This was roughly found to be true with Accelerator "A." On the other hand, when the tensile strength is increased at the expense of the elongation, as was found to be the case with magnesia, it will require an excessive load to effect the same extension. This decrease in the percentage elongation of mixtures which contained small amounts of magnesia was so marked that, with 1 per cent of this substance, an extension of one to nine was produced only by a load just short of that required to produce rupture, or break.

TABLE I.

Accelerator Used	Per Cent Accelerator	Sulphur Coefficient	Load in G. per Sq.Mm. Extended 1 to 9	Tensile Strength in G. per Sq.Mm. (at Break)	Per Cent Elongation at Break
Heavy Calcined Magnesia	0.00	0.684	163	181	962
	0.10	1.012		564	937
	0.25	1.287	501	774	950
	0.50	1.500	633	766	912
	0.75	1.873	832	914	900
	1.00	1.724	886	914	912
	1.25	1.821	883	1002	918
Accelerator "A"	0.00	0.684	163	181	962
	0.10	1.202	402	621	925
	0.25	1.609	630	871*	900*
	0.50	2.079	678	1153*	975*
	0.75	2.347	664	1170*	1025*
	1.00	2.518	636	1250*	1037*
	1.25	3.004	642	1223	1087

* These samples were pinched through by the clamps of the testing machine before the point of rupture, or break, was reached. Consequently, the results for tensile strength and elongation at break are low.

TABLE II.

Accelerator Used	Mixture	Per Cent Accelerator on Rubber — 0 Per Cent	5 Per Cent	10 Per Cent	15 Per Cent
Heavy Calcined Magnesia	First Latex	100	100	100	100

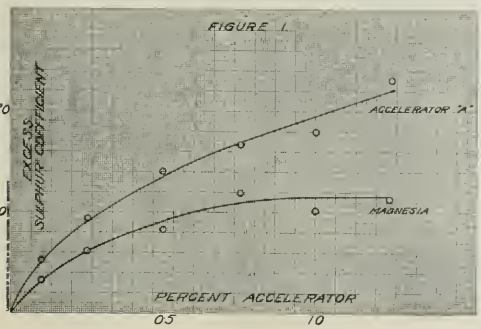
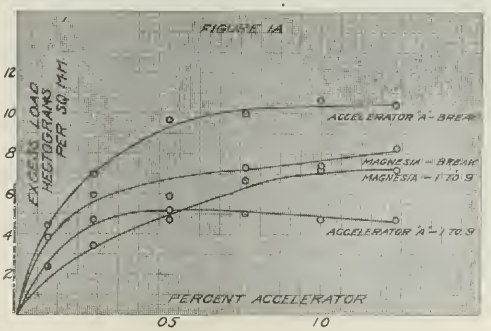
Lime	5	90	1,294	800	1.990
	10	45	1,565	750	2.926
	15	40	1,512	750	

Experiment 2

In the following work, where much larger amounts of inorganic accelerators were employed, it was desired that the effect of the accelerator as a filler should be minimized to the greatest possible extent. This was accomplished by employing mixtures which contained zinc oxide in such an excess that from 5 to 15 per cent of an inorganic accelerator could be included in the mixture, by replacement of a similar volume of zinc oxide, without decreasing the effect, or function, of the latter





substance (Tab. II). The sulphur content of the various mixtures was also cut down from 11 to 5 per cent, calculated upon the rubber. In this instance, and unlike the preceding experiments, the mixtures were vulcanized to maximum physical properties and their respective sulphur coefficients determined at this point. Portions of each of the mixtures were vulcanized in a platen press at 50 lb. steam pressure (298 deg. F.) over a wide range of times and the correct cure determined as the point of coincident, maximum tensile strength and percentage elongation (technical cure[12]). The sulphur coefficient of each mixture when vulcanized to this degree was then determined (Col. 6, Tab. III).

The results obtained show that, for all three of the accelerators used, the best physical properties were obtained with about 10 per cent of each in the mixture. The effects produced by light magnesia, heavy calcined magnesia and lime ranked in the order named. These differences, however, were small enough to be accounted for in the value of each of these substances as a filling material. However, it is evident that the value of these accelerators as filling materials is of limited extent, because, when present in larger amount (15 per cent), in each case the vulcanized mixtures showed inferior physical properties (Cols. 4 and 5, Tab. III). Moreover, the sulphur coefficients of the various mixtures were not found to reflect, or be a measure of, their physical properties. With both varieties of magnesia, the mixtures which contained 10 per cent of these substances were found to have lower sulphur coefficients than the mixtures which contained but 5 per cent, and the latter had lower coefficients than the control which was vulcanized without the assistance of an accelerator. On the other hand, the results obtained with lime were remarkable in that with 5 per cent of this substance, a much lower sulphur coefficient was obtained than in the case of the control, while with 10 per cent, contrary to the results obtained with magnesia, the sulphur coefficient was increased almost to that of the control.

In explanation of the results obtained with magnesia, we have consistently found that mixtures vulcanized quickly to maximum physical properties with the assistance of accelerators invariably show lower sulphur coefficients than similar mixtures also vulcanized to maximum physical properties but without the assistance of an accelerator. Frequently, much higher physical values are developed by those mixtures which contain accelerators. The same is true in lesser extent when a short period of vulcanization is effected by the use of higher temperatures. It is at least indicated that the time required to effect the cure of a given mixture is reflected both in its sulphur coefficient and physical properties.

Conclusions

In view of the foregoing results we have been led to the following:

1. That the physical properties of vulcanized rubber mixtures are more fully expressed in terms of the tensile strength and elongation at break than by the load required to effect an extension of one to nine.

2. When used in small amount magnesia is less active in accelerating vulcanization than certain organic accelerators, and it does not impart to the mixtures the physical improvement characteristic of the latter substances.

3. With mixtures which contain even small amounts of either inorganic or organic accelerators, no direct relationship exists between the sulphur coefficient and the state of cure as measured by the physical properties of the mixture.

4. When mixtures are vulcanized quickly with the assistance of inorganic accelerators, the correct state of cure, as reflected by their physical properties, is obtained at abnormally low sulphur coefficients.

Chemical Laboratories,

[4]This method as employed by H. P. Stevens [*India Rubber J.*, 55, (1918), 25, 5] and others, was found to be subject to correction, as it assumes that, in making comparisons between several samples, similar extensions will be effected by similar loads. Beadle and Stevens [*J. Soc. Chem. Ind.*, 30, (1911), 1421] have previously shown that the addition of as little as one-half of 1 per cent of zinc oxide or talc will produce a marked decrease in the extension of the vulcanized mixture. We have found the same to be true for small amounts of magnesia; certain organic accelerators, however, were found to increase the extension. With such the case, entirely erroneous results were obtained when two series of mixtures, one of which contained small amounts of magnesia and the other similar amounts of a strong organic accelerator, were tested by this method. We have found that comparisons made on the basis of the loads required to effect a given extension are less reliable than those obtained by comparing the tensile strength and percentage elongation at break.

[7]*Kolloid Z.*, 11, (1912), pp. 77-80. In the course of this work, Ditmar and Theiben also found that lime under vulcanizing conditions showed a greater tendency to form thio-compounds than other substances such as MgO, ZnO, etc. In view of this, and the results obtained in experiment 2, we are led to class the action of lime in accelerating vulcanization as more similar to that of litharge than to that of magnesia.

[14]Where less than 1 per cent of a mineral accelerator is worked into a rubber, it is extremely doubtful that it becomes uniformly distributed throughout the mass. When used in small amount (up to 3 per cent), and compared on the basis of their respective lead contents, we have found lead oleate to be more active in accelerating vulcanization than litharge. We attribute this largely to the unctuous nature of the lead oleate, which lends itself to a better incorporation with the rubber than litharge.

[15]*Chemist Analyst*, 15, (1916).

[16]The use of such a large quantity of sulphur is deprecated on the ground that it is in excess of the amount required to give a good vulcanization, particularly when employed in a mixture which also contains an accelerator. The excess of sulphur undoubtedly acts as a "filler," the effect of which is commented upon later in this experiment.

[17]Van Rossem (Reference No. 1, p. 214) has already noted that rubbers vulcanized with the assistance of certain organic accelerators show an increase in their percentage elongation at break. In this connection he has also found that, with similar amounts of an accelerator, the vulcanization of a rubber with a low viscosity value will be accelerated more than a rubber with a high viscosity value. This is explainable in light of the results of Spence and Kratz [*Kolloid Z.*, 14, (1914), p. 265], who found that small traces of acid decreased the viscosity of a rubber solution. As Van Heurn (*loc. cit.*) and others have found practically all accelerators of vulcanization to be basic, and retardents to be acidic, the accelerator is doubly effective in the case of rubbers of low viscosity in that it first counteracts the effect of the retarding agent and then accelerates the vulcanization. This will also account for the greater uniformity which is obtained in the rate of vulcanization of rubbers of widely different viscosity values when vulcanized with the assistance of an accelerator.

Australia Prohibits Dye Importations

Australia has, by Government proclamation, prohibited the importation of all dyes (except those of British origin), unless the written consent of the Minister of Commerce and Trade is secured.

Decomposition of Metals—II*

An Application of Theory to the Commercial Problem of Manufacturing Durable Alloys Containing Tin and Aluminium, With an Outline of Recommended Melting, Drawing and Annealing Practice for Certain Munitions

By COL. A. I. KRYNITZKY

THE WRITER studied the question of disease of metals especially in view of its importance in the manufacturing of ammunition. Rifle and gun cartridge cases, bodies, and the time rings of aluminium fuses, tin preserving jackets and tin tubes for some of the types of fuses—all these highly important parts are liable to decomposition under certain conditions of manufacturing and storage.

A noticeable decomposition was observed on the walls of the fuse tin tubes, which were covered with cracks, specks, projections and rough spots. In some cases such decomposition was followed by the partial destruction of metal. As these tubes were drawn cold, the decomposition may be due to the "disease of cold forging." Similar decomposition would be expected from the stamped tin preserving jackets which are used to seal the fuses.

Fig. 12 shows a preserving tin jacket for the 22-second Russian time fuse. This jacket is in the first stage of decomposition. Part of it, as may be seen from the illustration, is already destroyed and the rest is covered with rough spots and projecting grain formations, all of which indicate an imminent decay.

Fig. 13 shows an aluminium body of a Russian 22-second fuse, made in 1904-05 in Keller's factory (Austria), which has decomposed in a typical manner. Here the decomposition affected the body of the piece and was photographed in Fig. 14 at four magnifications without any preliminary preparation. Chemical analysis of this metal showed the following composition: Al, 94.1 per cent; Sn, 3.3 per cent; Cu, 1.8 per cent. Unfortunately the writer was unable to ascertain whether these parts were subjected to cold forging or pressing or to some other process. Fig. 15 shows the same decomposed spot under 80 diameters. It was impossible to polish these places, as the metal was too brittle, and the writer did not wish to impregnate the mass with rosin or similar cement, in order to avoid raising any question as to the meaning of the photographs. It was accordingly very difficult to focus properly the destroyed portion on account of its roughness. The writer succeeded in getting in the picture most of the scattered bright pins and rods among the gray mass.

It is understood that in all cases the diseases and decompositions were observed in very uniform and good castings. No doubt defects in uniformity of the alloys are detrimental to the service rendered by articles, but such defects have nothing to do with the decomposition of the metal as described heretofore.

In discussing the reasons for the "strange and unexplainable" appearance of cracks and other signs of decomposition in cartridge cases, General Matunin (about 1908) advanced the explanation that the cracks are due to the changes in physical condition (temperatures, etc.), chemical factors (moisture and sulphurous gases), but mainly to the inner stresses set up by the cold forging or drawing. This comes very close to Heyn's theory.

Therefore the following factors should be considered as the reasons why decomposition starts and which may take place at any time within the course of years a piece may be in storage:

1. Additional external forces.
2. Stresses, due to the uneven heating and cooling.
3. Surface injuries caused by mechanical action or due to cleaning and washing.

These have already been adequately discussed in the former article, except perhaps the last. Brass pieces under heavy stresses due to cold forging often decompose and are ruined merely by immersing them in mercury or solutions of mercury compounds, or when subjected to the action of ammonia vapors. Sometimes this action is started by merely covering brass with red mercury paint and exposing the piece for a while to the action of moisture, causing HgS to react with the copper in the alloy, decomposing into mercury metal and forming copper sulphide.

According to researches of Henry S. Rawdon[16] on the deterioration of Muntz metal by selective corrosion (dezincification) the results were "strongly suggestive that brass of the α-β type highly stressed is more prone to selective corrosion than when not so, particularly when the stress is highly localized; for example, at the base of a fine haircrack or a narrow groove." Specimens here were immersed for varying periods in 5 per cent sodium chloride solution.

Heyn and Bauer found in their extensive study of the local decomposition of aluminium ware that the metal is affected differently by water and salt solutions, depending upon the condition of the metal and the kind of solution. The decomposition may spread evenly over the whole surface, affecting the underlying metal but little, or it affects the aluminium in spots only, where it becomes covered with white specks, similar to mold. The metal in such spots becomes spongy, peels off and finally is destroyed. The latter effect was observed in heavily forged or drawn samples (for instance in cold drawn sheets). On annealed sheets the water practically had no effect.

Here, of course, the main cause of the disease was cold drawing, and the internal stresses so set up may be

*The first installment of this article was published in CHEMICAL & METALLURGICAL ENGINEERING, Vol. 20, No. 6, March 15, 1919, p. 277.

[16] "Typical Cases of the Deterioration of Muntz Metal (60:40 Brass) by Selective Corrosion," by Henry S. Rawdon. Technologic paper of the Bureau of Standards, No. 103, December 19, 1917.

removed by a proper anneal. Heyn and Bauer mention 500 deg. C. as a proper annealing temperature. The writer also has frequently observed the slight spotty decomposition of aluminium.

It was stated in the *Russian Artillery Journal* in 1912 that in many cases aluminium cables used for telephone, telegraph and trolley wires failed during and after sleet storms without any apparent cause. In such cases the aluminium has shown plainly a crystalline fracture. Aluminium wires suffer particularly near the seashore and in the vicinity of factories emitting vapor and fume of muriatic acid and alkalies. The writer thinks that such cases are evidence of disease in cold-drawn wires, which possibly could have been prevented by previous annealing.

Captain Crard of the French army in his article "Cartridge and Bullet Brass and Electrolytic Copper" (*Rev. de Met.*, 1909) brought forth numerical values for the safe compression of brass without intermediate

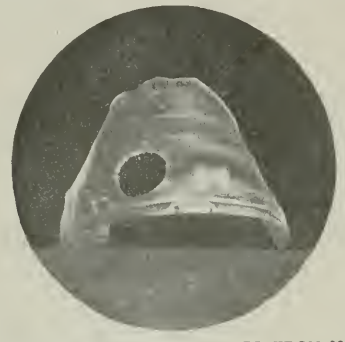

FIG. 12. DECOMPOSED TIN JACKET FROM 22-SEC. TIME FUSE

annealing. He found that the maximum possible deformation for brass should not exceed 200 per cent of the final cross-section, which corresponds to 33 per cent of the original thickness. He stated further that a stable condition follows tempering at from 350 to 450 deg. C. and complete annealing at from 750 to 830 deg. C. After an annealing at temperatures below 350 deg., brass does not remain stable for any length of time, but will develop cracks in the thinner parts. Temperatures above 830 deg. ruin the brass, causing it to lose its strength and durability and to become brittle.

In his treatise[17] Colonel Gronoff discusses the methods for preventing cracks in cartridge cases when stored for a length of time, and states that the cases should be made of metal with a uniform crystalline structure, avoiding excessive deformations in their manufacture, and between passes should be annealed at temperature near 750 deg. C. The mouths of the cases must be submitted besides to a special annealing. As may be concluded from the very extensive researches of Colonel Kourdumoff in Mickall Artillery Academy, Petrograd, Russia (his "Monograph of Copper-Zinc Alloys"), the tempering temperatures for commercial brasses range from about 200 to 400 deg. C.

[17] "Influence of the Methods of Manufacturing on the Mechanical Properties and Crystalline Structure of Worked Brass and Cupronickel and Tendency of These Alloys to Make Cartridge Cases With Ragged Edges," by Gronoff, *Bulletin*, Russian Technical Society, 1911, p. 401.

According to W. B. Price[18], the temperature at which internal strains of brass for cartridge cases are positively reduced if not entirely eliminated is about 500 deg F. (260 deg. C.). The author in his practice in Russia as a rule submitted all rolled and drawn bars and also certain castings of commercial brasses, tin bronze (copper with 8 per cent of tin and about 0.09 per cent of phosphorus), and aluminium bronze (copper with

FIG. 13. BODY OF ALUMINIUM TIME FUSE

9 per cent aluminium) for final heat treatment at 250 to 500 deg. C. (for castings at higher temperatures), according to the mechanical properties desired. Cold rolled rods (also some castings) made of aluminium or its alloys were submitted to a final heat treatment at 450 to 500 deg. C. Thus to prevent deterioration all strained metals must be subjected to a final heat treatment at a certain temperature for each metal. The other methods of removing initial stresses were not mentioned simply because the writer never applied them in his practice and can say nothing positively.

FIG. 14. DECAYED SPOT IN FIG. 13 AT 4 MAGNIFICATIONS

Concerning season cracks in brasses it may be pointed out that according to the researches of Professors Carpenter and Edwards we might expect a transformation

[18] "The Prevention of Season and Corrosion Cracking of Brass Artillery Cases by Special Heat Treatment," by W. B. Price. *Proceedings*, American Society for Testing Materials, 1918, Vol. XVIII, Part II, pp. 179-188.

of β crystals into brittle α crystals[19] to occur in certain brasses under certain conditions.

Proper Manufacturing Procedure for Aluminium Parts and Their Composition

In many countries parts of time fuses are now made from aluminium which contains a little copper and other metals, so that in reality it is a high-aluminium alloy. Possibly, however, copper causes aluminium to be less susceptible to the action of chemical reagents and to decomposition, as defined above. The facts and theories described offer sufficient basis for judging the best manufacturing methods for aluminium parts of time fuses.

Time rings, for instance, which are used in the assembly of the fuses, are flat disks with an open circular powder groove. These rings may be made according to one of the following main methods:

1. Cast and then stamped one way or the other to final dimension.

2. Cast and stamped, leaving in the powder groove sufficient stock for finishing in the milling machine.

3. Cast and compressed without powder groove, which is then milled out.

4. Round rods cast, cold rolled, rings sawed off and finished on machines.

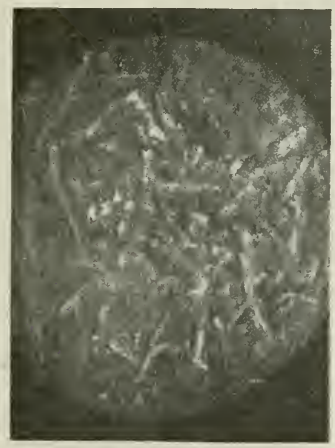

FIG. 15. DECAYED SPOT IN FIG. 13 AT 80 MAGNIFICATIONS

5. Round rods cast, cold rolled, annealed, rings sawed off and finished on machines.

6. Round rods cast, hot rolled, rings sawed off and finished on machines.

Prevention of Decomposition

In regard to prevention of possible decomposition and self-destruction, methods 5 and 6 are, in the writer's opinion, the best. As regards composition it may be pointed out that after many experiments it was found that the best rich aluminium alloy for the time fuses is aluminium with 2.5 per cent to 2.9 per cent of copper.[20] Alloys containing more than 3 per cent of copper are too brittle to be cold forged.

All Russian 22-second aluminium time fuses for the last 11 years in Russia and also in this country were made of this alloy. Although it was very well known that magnesium considerably ameliorates rich aluminium alloys, the writer failed to obtain good results with this element because, first, he couldn't get at that time solid magnesium and was compelled to experiment with magnesium in powder or with small pieces, and,

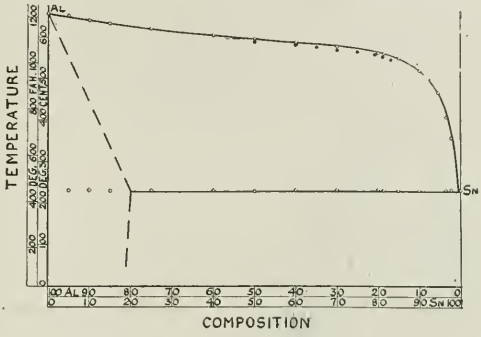

FIG. 16. EQUILIBRIUM DIAGRAM FOR ALUMINIUM-TIN ALLOYS, FROM GULLIVER

second, in rare cases when he succeeded in keeping magnesium within alloy the latter was rather brittle. For the same reason he failed to manufacture duraluminium.

Accelerating Effect of Tin on the Decomposition of Rich Aluminium Alloy

This effect was illustrated in Figs. 13, 14 and 15, showing the decomposition of tin-bearing aluminium alloy. It should appear that such a disintegration occurred not only in such a short time[21] (about eight years) but was to be found only with the above-mentioned time fuses made of an alloy: aluminium with 1.80 per cent of copper and 3.3 per cent of tin.

According to the accompanying equilibrium diagram, Fig. 16, aluminium-tin alloys belong to the class which does not form chemical compounds and when cooled quickly they contain more or less of crystals of nearly pure tin. If there is present free tin in an alloy, we can expect all the phenomena which accompany the decomposition of pure tin. Investigating this question further, we conclude that since pure tin can be found in binary, ternary, or multinary aluminium alloys in its unstable condition, then even a very small addition of tin to the alloy may serve as a source of the "plague." Furthermore, such a small quantity of tin, while decomposing itself, may catalyze decomposition in the other component metals. In this way, tin acts as a poison toward its neighbors.

[19] Although according to O. F. Hudson we have to deal here with a polymorphic change β into β_1. See "The Critical Point at 460 deg. C. in Zinc-Copper Alloys." *Journal*, Institute of Metals, Vol. XII, 1914, pp. 89-99.

[20] It should be noted that this alloy, like other rich aluminium alloys, generally develops some troubles in machining because of the presence of small black particles, which are so hard that the best tools are broken immediately upon touching them. Many experiments were made by the writer with different methods of molding and casting, with the result that this important problem was not solved. Probably these particles are some hard form of carbon, or a chemical compound of carbon with silicon, or of silicon with aluminium. In any case this problem is open to investigation.

[21] It is to be remembered that Russian time fuses are stored in hermetical metal boxes.

The objection may be raised to the application of the aluminium-tin diagram to the ternary alloy aluminium-tin-copper. But in the aluminium-copper equilibrium diagram, Fig. 17, we have a chemical compound or solid solution, so that really there would not be any free copper in the composition used in the fuses which decomposed. Comparing the results of these two diagrams, we may deduce with reasonable certainty that even with the ternary alloy we may expect free tin on quick cooling and without careful annealing.

Therefore, although a small addition of tin to aluminium alloys is very attractive, as it renders the metal very satisfactory for machining, even without a lubricant, and in spite of the fact that small quantities of it may be dissolved by careful annealing this element

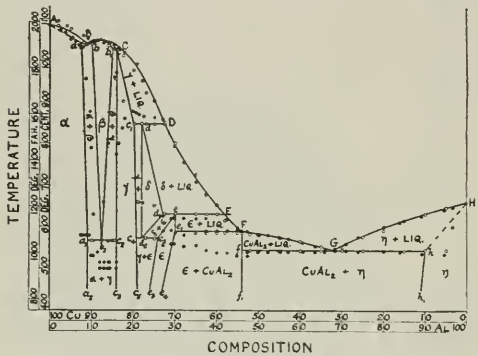

FIG. 17. EQUILIBRIUM DIAGRAM FOR COPPER-ALUMINIUM ALLOYS, FROM GULLIVER

was always avoided and, in the author's opinion, should be avoided when the articles must be kept for a long time, and particularly when cold working is to be used in their fabrication.

As regards a certain contradiction existing between the aluminium-tin alloy solidification diagram which is shown here and the writer's explanation it might be mentioned that at the time when the writer observed disintegration to take place in the aluminium parts of the time fuses considered, he had in mind Portevin's statement[22] in which he wrote in very positive terms that for aluminium-tin alloys there exists neither a chemical compound nor a solid solution.

In the meantime microscopic examination proved, as it was thought, that pure tin occurred in the network and in some spots on the grains and, as is mentioned above, the writer explained the disintegration of this metal as being due to an allotropic modification of the tin in which the tin assumed the brittle form and facilitated disintegration in two ways: (1) Say like bismuth in case of its alloy with copper, where each ductile crystal of copper is surrounded by a weak and brittle envelope of bismuth. (2) As a catalyzer.

Thus the writer explained this phenomenon, but if we have here a solid solution and not pure tin, then his interpretation is incorrect and we must seek some other explanation. Most of these facts and their interpretations are very well known, since they have repeatedly been stated in the literature and if in spite of this the author has ventured to repeat them again it was only in order to bring them together with some of his own observations.

Bureau of Standards,
Washington, D. C.

[22] La présence de l'horizontale eutectique à 229° C. sur toute l'étendue du diagramme montre, qu'il n'existe ni solution solide ni composé défini, à moins cependant que ce dernier ne se forme très lentement. La constation qu'un aliage à 50% Sn maintenu cinq heures constamment agité à 710°–720° sans que cela modifie la courbe de refroidissement rend cette dernière hypothèse improbable." "Aluminum étain," M. A. Portevin, *Revue de Metallurgie*, 1908, 5, pp. 292-293.

A Correction

In the first installment of this article, published in this journal on March 15, a typographical error confused the sense. On page 281, first column, seven lines from the bottom, the sentences should read: According to W. H. Bassett, with wrought brasses in the α phase, the cracks always pass between the crystals. When both the α and β phases are present, the cracks pass through the beta.

War Trade Board Rulings

Importation of Dyestuffs.—The War Trade Board announces that hereafter all applications for licenses to import dyes or dyestuffs must be accompanied by a statement giving complete specifications of the character of the dyes or dyestuffs proposed to be imported. A supplemental information sheet, procurable from the Bureau of Imports, Washington, or from any branch office of the board, should be used for this purpose.

Importation of Ferromanganese and Spiegeleisen.—The restrictions heretofore existing upon the importation of ferromanganese and spiegeleisen have been removed and licenses to import these commodities will now be issued freely when the applications are otherwise in order. Importation of these commodities from the United Kingdom, France, Italy, Belgium or Japan, or from their possessions, protectorates, colonies or dominions, may now be made under General Import License PBF No. 34.—W. T. B. R. 674.

Disposal of Government Spelter

Tentative arrangements for the disposition of the War Department's surplus stock of spelter were made at a conference held in the office of the Director of Sales, which was attended by War Department officials and a committee representing the American Zinc Institute. A complete report was presented by the Government, the figures of surplus shown being considerably less than anticipated by the members of the committee, and it was arranged that the War Department would dispose of its surplus spelter through the zinc committee as representing the producers of zinc. This arrangement will tend to relieve any situation which might arise in the industry from the sale of this property by the War Department itself.

New General Import License

A general import license similar to PBF No. 34, but covering imports into the United States from Mexico, Cuba, Haiti, Santo Domingo and all countries of Central and South America, except British and French possessions, has been issued by the War Trade Board. Individual licenses are required for nitrate of potash, rubber and tungsten ore, in addition to the items mentioned under PBF No. 34 (see page 319), with the exception of ferromanganese and spiegeleisen.

Bituminous Roofing Materials and Construction—I

Genesis of the Roof—Importance of Incline, Types of Roofing Adopted: Flat Roof, Built-Up Felt and Pitch—Roofing Pitches, Weathering Properties—Felts, Sources, Processes of Manufacture

By GEORGE LANDIS WILSON

ROOFS, as developed in the progress of civilization, originally were provided with faces which consisted of overlapping units laid together on an incline so as to break joints with the outer and lower edges toward the drainage point, and each unit projecting beyond the contiguous higher units. Grasses and small twigs commonly known as thatch, slates, flagstone and tiles, shingles made of bark, wood and various composite materials are examples of such facings. All of these required decks, or the equivalent, set at an angle from the horizontal sufficient to direct water to a point where it could not flow back or pass down through the several layers of units and permit leakage through the roof.

For this reason roof design became a problem in the intersection of the faces of pyramids, plinths and polyhedral contours in endless variety.

In the course of time sundry materials in the form of impervious continuous membranes were used as substitutes for the various scale-like applications of material. These were metals, made continuous by the use of soldered seams, continuous membranes built up out of layers of fabric or felt, alternating with various pitch or other water-resisting compositions, and prepared roofings, factory made out of felt saturated with waterproofing materials having the seams cemented together with similar substances. As the use of the various membranes progressed the roof decks used with them were given less slope for the reason that much labor and material are saved when the intricate framings and decks are abandoned, until the "flat roof" became the standard and usual type of construction in many places.

Roof Incline Has Important Bearing

It will be seen that the incline of the roof has a most important bearing in selecting the type of roofing best suited for a given structure. Thus, in general, bituminous roof coverings are divided into two classes; first, those employing a continuous layer impervious to water, the same as in the case of membrane waterproofing used to protect against water pressure below the ground level; and second, those employing separate overlapping units which shed water, as do shingles, tile, etc. While there is a considerable overlapping in the practical application of these two general types, the impervious continuous layer being applicable to any incline, there is a minimum incline below which shingle type is not practicable.

Prepared roofings in roll or sheet form should, perhaps, be considered as a third class by reason of their wider adaptability to almost every roofing condition, although it is generally conceded that they are more serviceable when used on inclines exceeding 2 in. to the foot than on anything less, and that 1 in. to the foot is the minimum, except where unusual and impracticable precautions are taken to avoid exposed nailings and protect against leaks under the exposed laps.

A fundamental to be borne in mind is, in proportion as the roof incline is reduced the greater should be the water-resistant power and assured continuity of the roof covering.

As this article treats only of bituminous roof coverings, it will discuss separately, first, the "built-up" type particularly suited for flat roofs; second, prepared roofings, either in roll or shingle form, particularly suited for roofs of steeper incline.

Conclusive Tests Not Available

Wooden shingles, slate, clay or cement tile, galvanized iron and tin are materials regarding which there is an abundance of general as well as technical information in such form as to be readily available for any one interested in specifying or buying roofing; but such is not the case regarding roofings in which bitumen—coal tar or asphalt—is employed, for the reason that bitumen, which is a hydrocarbon, is the most complex substance with which chemists have to deal. There are probably more than forty different natural sources of bitumens used regularly in the manufacture of roofing, each varying to a more or less degree from the other in chemical or physical characteristics, and each capable to a greater or less degree of mixture with some or all of the others, and each supply, or combination, because of some commercial, physical or chemical characteristics, having its own support among the manufacturers of bituminous roof coverings.

Furthermore there has been no series of tests standardized and accepted as proving that a particular piece of roofing made from a certain material and by a certain process is more suitable for a given purpose than another piece of roofing made from a different material or by a different process. Also, most of the tests that have been suggested are workable only when conducted in a well equipped laboratory, and by some one thoroughly familiar with bitumens and also with their practical uses. Therefore such tests are not available for the average buyer of roofings. As a result each manufacturer has been free to make such claims for his own particular product as his judgment or business necessity has suggested, in most cases without danger of positive and conclusive contradiction; hence there have been large amounts of bituminous roofing materials sold on the basis of claims of general or particular merit which had no justification.

In spite of this condition, which is inherent in the

business and exists today to as large an extent as at any time in the history of the art, the industry has grown during the past seventy years from nothing to such importance that its products annually are used to cover a larger roofed area than are all other types of roofing combined, and in the United States alone represents an investment variously estimated at from $40,000,000 to $60,000,000. This of itself is evidence of the inherent merit of bitumen as a roof covering. The following is offered with the hope that it will in some degree assist the buying public to obtain better value than has been generally the case in the past. We would not presume at this stage in the development of the industry, or of the technical knowledge regarding its supplies, processes and products, to provide an infallible guide.

Functions of a Roof

On the part of the buyer mistakes of judgment, aside from those due to lack of technical knowledge of the commodity, can be traced to confused thinking regarding the results really wanted. Hence it is desirable first to set out clearly the functions of a roof in combination with its joinings and flashings, which serve to complete the connection with projections and walls.

At this time it is also well to remember that every building, except it be a monument, is primarily erected to provide shelter from the weather, and the basic element in such shelter is a serviceable roof. Everything else is really collateral to the principal aim.

Couple with this the fact that in any community the cost of the roofing material used averages less than 1 per cent of the total cost of the finished structures, and misguided effort to make petty savings by cutting either quantity, quality or workmanship here look ridiculous. From the standpoint of the owner, whose entire investment is safeguarded in its most important aspect at such a small relative cost by the roof face, and also of his legitimate agents, the architect and constructing engineer, or contractor, employed and held responsible solely because they are presumed to be skillful and discriminating in selecting that which will be most useful to him, the roof is no place to try experiments. The possible money saving is trifling, while the probable expense, in the event of failure, is large.

Table No. 1—Reasons for Applying Roof Faces, Joinings and Flashings.

(Stated in the usual order of consequence.)

1. To waterproof plane surfaces against rain, melted snow and ice.
2. To join plane surfaces to projections and walls so as to exclude driving rain and snow.
3. To care automatically or compensate for movement and cracks in decks and walls.
4. To protect the most exposed part of premises against spread of conflagration.
5. To provide means for blanketing fire in the building where it starts.
6. To prevent air leaks or drafts, caused by wind.
7. To provide a moderate degree of protection against heat and cold.
8. To provide a presentable architectural finish or uniform effect.

Brief Summarization

The means for accomplishing these results by the use of bituminous materials are briefly summarized as follows:

Table No. II.—Functions of the Substances Used in Bituminous Roof Faces.

1. *Bituminous Waterproofing Material:*
   (*a*) Held as a solid mass of saturant, absorbed in a sheet of felt and on its surface; and also used as a cement at the narrow laps of the sheets when laid. Or
   (*b*) Spread in layers between successive sheets of saturated felt widely overlapped, and also spread over the top to form a continuous membrane.
2. *Absorbent Felt or Textile Used:*
   (*a*) To retain in place greater quantities or more layers of bitumen pitch of suitable softness than would stay by itself or if mixed with pigments or fillers. And
   (*b*) To provide a body of material having sufficient tensile strength and extensibility to bridge all normal cracks and similar changes as they occur from time to time, due to settlement or curing of the walls and decks.
3. *Top Finishing Material:*
   (*a*) To retain an abnormal amount of bitumen pitch in the most exposed place.
   (*b*) To withstand the wear and action of the elements and also abuse by men.
   (*c*) To provide a fire-resisting face to meet conflagration hazards.
   (*d*) To make an attractive, uniform appearance.
   (*e*) On prepared roofing, to supply a dry side, to prevent adhesion and insure easy delivery from the roll when used. Materials so used are cement concrete, bitumen, mastic, vitrified brick, flat tile, small slates, gravel, slag, crushed rock, crushed slate, sand, asbestos fiber, mica flakes or powdered soapstone.

Waterproofing Not a Simple Matter

It is not so simple a matter as it appears to provide a roofing material which will remain permanently waterproof. All viscous materials contain a proportion of oils or oil-like matter having a tendency to evaporate slowly when exposed to the air at ordinary temperatures, precisely as water with a boiling point of 212 deg. F. evaporates rapidly at a temperature of 60 deg. Many of these substances become relatively hard, assuming a crystalline form when they become cold.

The strains placed upon roof faces as the result of extremes in temperature between summer heat and winter cold are evident. In those cities of the U. S. north of 40 deg. latitude, roof surface temperatures as high as 150 deg. above and as low as 20 deg. below zero, F., are usual. It is impossible to make the coefficients of expansion and contraction, due to variable temperature, the same for roof surfaces, roof decks and roof enclosures. The roof face is called upon to provide the element of compensation due to the fixity of construction in the building of which it is a part.

Roofing Pitch

For this reason it is desirable that any bitumen used for roofing materials shall be of a nature that will fuse or run together at a temperature of few degrees below the maximum temperature to which it will be subjected during hot weather. At the same time this fusing quality must be obtained through the presence of oils which are not easily evaporated under conditions of use. The natural oils left in coal-tar roofing pitch during the process of distillation with scientific exactness, to insure a melting point of 140 to 150 deg., as desired, attain these results in an ideal manner. It is difficult to secure equal results when foreign oils are added to bitumen bases. They mix so as to reduce general melting points at relatively high temperatures, say 250 to 400 deg. F., but they do not blend so as to insure the restoration of lesions liable to occur during cold weather.

The causes behind these conditions encountered in practice are indicated by a view of the components in pitch.

Table No. III—Elements in Bitumen Pitches.

1. Gums, which in the last analysis are in the nature of fossilized vegetable tars.
2. Oils which serve as solvents for the gums, and are stable at temperatures less than 150 deg. F.
3. Solvents, which evaporate very slowly at various temperatures lower than 150 deg. F.
4. Fixed mineral matter, composed of infinitely small crystalline units, is usually present.
5. Some asphalts carry wax which is different from gums, because of its coarse crystalline formation, trifling tensile strength and marked inflammability. Such elements are eliminated from coal tar in the making.
6. Traces of sundry alkaline bases which, with the addition of small amounts of water and moderate heat, develop into reagents that attack oils and gums are found in some asphalts. Processes of coal-tar distillation divorce these materials from coal-tar pitch.

Destructive Reactions

In this connection it must be remembered that the water deposited upon roofs is soft water ready to take up promptly in solution every impurity it finds. Roofs are most numerous in places where there are industries and population. The fuels most commonly used in such centers are constantly delivering into the air and depositing upon all the roofs a variety of acid bases which are readily soluble in water. The wastes of civilized life and the ordinary processes of nature constantly produce a supply of micro-organisms which multiply rapidly when water or mere moisture is present and become the source of fungi and molds that cause decay. Weather Bureau records show that rainfall on most occasions is very small in amount, often merely a trace. This means that water sufficient to dissolve all the impurities is frequently present but as a rule not in sufficient quantity to provide a real flow or a flooded washing effect. This chain of circumstances, properly considered, enables one to picture the destructive reactions which repeatedly take place if roofing bitumens contain any susceptible impurities or are so deficient in quantity as to permit any part of the felt to absorb water.

Table No. IV—Some of the Sources From Which Roofing Pitches Are Derived.

1. Tar by-product from coal remaining after production of gas.
2. Tar by-product from coal remaining after the production of coke.
3. Tar produced in the manufacture of water-gas and oil-gas.
4. Deposits of native asphalt which are cut in various oils.
5. Heavy residuals from distillation of petroleum crude oil having asphalt base.
6. Heavy residuals from distillation of petroleum crude oil having paraffine or mixed base.
7. Heavy by-products from treatment of oil-bearing shale rock, lignite or peat.
8. Tar by-products from refining of vegetable oils.
9. Tar and resins from tree exudations and wood-distilling processes.

The methods of treatment to which by-products and residuals are subjected produce pitches of various characteristics. For example, some asphalts are made by oxidizing and polymerizing the hydrocarbons from petroleum sources through the process of blowing heated air or air with steam through the mass for a considerable period of time. Similar treatment with sulphur has been used. The same basic residuals are sometimes concentrated by the mere application of steam heat. The results are not identical. When heated to proper temperature they are all readily absorbed by sheets of felt, but they do not present equal weather-resisting qualities.

The foregoing table does not include all of the possible origins of pitch. Those mentioned are important, and the variety serves to suggest the diversity in the nature of the products which spring from them. Couple with this basic natural variations in the materials used as a starting point, the changes in hydrocarbons caused by heat at different temperatures and during different periods of exposure, the varying degree of skill possessed by operators, or the entire lack of it, the degree of capacity and willingness to test raw materials before refinement or distillation, and the suitability or degree of completeness in the equipment at the works where the pitch is prepared for the market, and there is reason enough to recognize the value to the buyer of established brands sponsored by reputable and responsible manufacturers.

Bitumen as used in saturating felts for roofing must be brought to a state of viscosity which permits it to penetrate the felt. The best method of securing this result is the application of heat, provided the melting point of the pitch is low enough so that the degree of heat required does not damage the felt fabric. Attempts are made to accomplish the result by the use of oils or solvents in the nature of thinners, following the general practice of the varnish trade, so as to secure a saturating material which will penetrate and also set up at normal temperature. This process requires the use of some thinners which evaporate rapidly, and others which evaporate slowly, with the result that the substance of the bitumen becomes cellular and finally impaired to such an extent that the sheet becomes hard and brittle. There are a number of foreign solvents which are effective enough when considered merely as thinners or as waterproofing materials in themselves that are unsuitable for roofing, either because of relatively high inflammability, absence of gum characteristics, lack of synthetic quality, disposition to carbonize at low degrees of heat or readiness to evaporate.

When skillfully used, oils and solvents which have such affinity for the bitumen treated as to form a true combination (instead of a mere mixture) solely for the purpose of lowering the melting point of the bitumen and insuring fixation at normal temperature are serviceable, provided they are stable.

Bitumens used as coatings for prepared roofings and for cementing together and surfacing several layers of felt as applied on a roof surface are generally of a higher melting point than bitumens used as a saturant, but they must also be liquid when used and become solid in a relatively short time at atmospheric temperature. The higher melting point required is obtained either by using different bitumens as a base, or by distillation or oxidation, or by the addition of finely ground inert mineral in the form of silica, slate flour, gypsum, powdered lime, etc. The addition of the inert material is generally for the purpose of lessening the cost, and such mixtures are not as serviceable as pure bitumen except for special purposes outside of the scope of this article.

Felt originally was a specific term used to designate a stuff made of matted wool and hair worked into a compact substance by rolling or pressing and held together by a size made from a weak solution of glue, the dregs of wine or any other convenient viscous material.

Later it became a generic term also applied to any relatively thick sheet which is of comparatively open structure when measured by the standards set up by practice in the paper and cardboard trades. Thus carpet felt, building felt and deadening felt came into regular use at a very early date to prevent the wind from blowing through houses. It was supplied in rolls, as distinguished from flat sheets like paper and strawboard, so naturally fell into a class by itself.

In the United States the history of felt base roofing dates from its employment in gravel roofing, which began about 1845. Naturally the roll felts common in the building trade were used when there was need for a medium to hold a saturation of tar, preliminary to its early application with layers of pine pitch to make a roof face. Coal-tar pitch was first used about 1850. The name "saturated roofing felt" has persisted. The common characteristic of all the felts when considered for saturation lies in their open texture, freedom from inert material and the true absorbent qualities of their fibers, which are truly impregnated and not merely coated by the saturating material. For example, water permeates a body of sand or gravel, yet drains out of it freely and completely; while water impregnates or saturates a sponge or mass of fiber and is removable only by evaporation.

Table No. V—Various Materials Used in Roofing Felts.

1. Animal and vegetable fibers, as wool, cotton and linen, obtained from the maceration of rags and rope.
2. Old paper, jute, flax-tow, hemp, etc.
3. Linters and mill fibers of the waste class.
4. Fibrous wood products obtained by the sulphite and soda process.
5. Mineral fibers, usually of the asbestos series, but sometimes blown slag, mostly non-absorbent.
6. Clay, powdered limestone or like earths used as fillers and weight-makers which absorb little saturant and contribute no strength.
7. Sometimes woven textiles are used as reinforcement sheets.
8. Rarely, wire mesh, wire strands and fiber cords or strings are used for reinforcement.

Processes of Manufacture

The processes of manufacture in the production of roofing felts follow closely the processes established in the writing and wrapping paper industries. However, sorting, cutting, dusting, boiling, washing and beating are not carried so far, and bleaching is unnecessary. The machine used for changing the pulp-like mass into sheets is usually of the cylinder type, although the Fourdrinier type is sometimes used. Press rolls are not set tight, drying cylinders are ample in number and smoothing rolls provide all the finish the dry felt requires. The production of felt for saturating purposes requires a fine balancing of absorbent qualities, tensile strength and durability. "Wool felt" is a misnomer. Felt 100 per cent wool would be entirely unsuited for roofing purposes. A high grade roofing felt contains from 50 to 75 per cent of cotton fiber, a negligible percentage of wool, and oftentimes old papers are used to a limited extent.

Felt when saturated and then surfaced with bitumen becomes roofing and is known as prepared roofing or ready roofing, or felt base shingles, depending on whether furnished in rolls or shingle form, and is a finished product ready for use by itself as a roof covering. Felt when saturated with bitumen but not surfaced must have bitumen used with it when it is applied as a roof covering. While saturated felt by itself will shed water, it is not what would be termed waterproof and will disintegrate rapidly when exposed to the weather. The standard weight of saturated felt for roofing purposes is 15 lb. to the 100 sq.ft., with an allowable variation of one pound either way. Approximately 60 per cent of this weight is saturant and 40 per cent felt, but these percentages vary depending on the viscosity of the saturant and the absorbent qualities of the felt. There are several other weights of felt manufactured because of demand to meet competitive conditions, but there is no reason for any other weight than 15-lb. saturated felt for roofing purposes.

Burning Lime in a Gas-Fired Continuous Kiln

By W. D. Mount

THIS paper is presented for the purpose of drawing attention of lime manufacturers to a system by which lime can be burned economically in a kiln 8-foot diameter with a capacity of 25 tons per day. The ratio of coal to lime is 1 to 5 or 6, depending on the quality of the coal. Cost of repairs per ton of lime is lowered.

The conversion of calcium carbonate to lime is a chemical process which may be conducted without any chemical knowledge, and with but a moderate amount of technical skill. As the carbonate is decomposed at a red heat, it is apparently only necessary to apply the heat for a short period, and the result is lime, regardless of considerations of economy.

"Every step and every factor, however, in the operation of lime burning has a definite significance, and the production of high-grade lime with high-grade economy is as truly a technical process demanding skill and knowledge as any other chemical manufacture. There is need of trained chemists and engineers in this industry to put it upon a distinctly scientific plane."[1]

As every step and factor in the process have a definite bearing on the final outcome, they must be under complete and constant chemical control. Therefore, it is not only necessary that such control be provided, but the design of the apparatus must be of a character that the control can be made effective; otherwise, it will be impossible to realize that continuity of operation and co-ordination of the various factors, so essential to uniformity in quality and quantity of output and the attainment of the highest efficiency and economy.

Engineering Design and Chemical Control Essential

It is doubtful if the salary paid a trained chemist could be invested to better advantage, or be more productive of desired results in any industry than in the manufacture of lime and lime products. However, as already indicated, it is not a problem for the chemist alone, but his work must go hand in hand with that of the engineer. Chemical control cannot be effective in the highest degree unless the design is of a character

[1] Geological Survey of Ohio Bulletins 4 and 5, Orton & Peppel.

to permit the regulation of all those factors having a direct bearing on the final result.

The foregoing statements lead naturally to a consideration of problems of design, preliminary to which, however, it is well to call attention to certain specific factors having a direct and important bearing on the operation of the process. It seems to be the accepted opinion, backed by many years of practical experience, that wood, both technically and as regards quality of product, is the most desirable fuel. It is not my intention, however, to consider the merits of a fuel now unattainable, or at least practically so, but to accept without discussion the most generally available fuel approximating the good qualities of wood, namely, producer-gas made from bituminous coal low in sulphur, in a modern producer-gas machine, so located and operated as to deliver to the kilns the maximum number of B.t.u. per cubic foot of gas. Moreover, that coal will be used, regardless of price, which will give the greatest number of pounds of lime for a dollar.

It would seem axiomatic that a kiln of the shaft type, other things being equal, will have the highest fuel economy when operated so as to be cold at the top and cold at the bottom, and that its capacity, under these conditions, will be greatest when discharging continuously.

"Temperature of burning is an important factor, both in the quality of the product and in the economy of production. Economy in manufacture requires that the temperature of burning should not be greatly beyond that needed for the complete removal of carbon dioxide. . . . The time required for slacking limes burned at different temperatures shows clearly that the sensitiveness of quality of the lime is materially affected by any great overheating."[2]

Importance of Temperature Control

In the use of heat it is necessary, not only as effecting the reaction, but on the grounds of economy, that definite control of temperatures be possible, and in many industrial operations control must be effective to within a few degrees in order to insure the greatest success. Therefore, it seems essential in a well designed kiln for producing lime, that suitable provision should be made for determining and maintaining the proper temperature necessary to the production of the best quality of lime possible from the stone to be burned. Overburning from too high temperatures, or the production of core from insufficient heat are alike undesirable qualities. Fortunately the burning of calcium carbonate to lime is not like some other heat operations, in that a fairly wide range of temperatures is permissible without materially endangering the quality of the product; though from motives of economy, as affected by kiln capacity, it is desirable to approach as near as possible the safety limit of the maximum allowable temperature as the quality of the product will admit. Hence the importance of close regulation, regardless of the considerable range of temperature within which the kiln may be safely operated.

The question of draft is important, not only as affecting the capacity of the kiln, but from the standpoint of economy. Induced draft is preferred, as it is independent of height of kiln, and size of material charged, and can be controlled by the operator in charge.

When de-carbonizing has proceeded to the point where all gas has been expelled, the lime should be promptly removed from the zone of intense heat into the cooling zone; first, to prevent "dead burning" and recarbonization, due to exposure to the combustion gases; and second, that the cooling may be progressive following the principle of the counter current, the hot lime giving up its heat to the incoming air for combustion.

The removal of the lime from the reaction zone to the cooling zone, and its final discharge from the kiln should be continuous. This is an important feature of the design, inasmuch as the discharge mechanism will bring about a slight, but perceptible, movement through the entire charge in the kiln, tending to stabilize the draft, prevent clinkering and holding up of the charge, and improving the life of the brick lining.

Time Required for the Reaction

The length of time required for the limestone to pass through the reaction zone will depend on several factors:

First: The size of the limestone blocks fed to the kiln. The smaller the blocks the less will be the time necessary for the heat to reach their center, other things being equal.

Second: The amount of pre-heating the stone has had, prior to reaching the reaction zone, as well as the kiln pressure.

Third: The nature of the fire, its volume and intensity, and its close regulation.

Fourth: Continuous movement of the stone through the reaction zone.

If a continuous stream of stone can be kept passing through the reaction zone at a rate that would insure the complete burning of the stone to lime, and no more. it would be of advantage to the quantity and quality of the product, for the reason that the constant movement would keep turning the stone, giving equal exposure on all surfaces.

Design of Continuous Kiln

The design of the continuous discharge gas-fired kiln is not, as will be noted in the illustration, altogether a radical departure from the standard of the more modern kilns of the shaft type. Neither the use of producer gas, induced draft, nor the idea of cold lime from the bottom of the kiln are essentially new. On the contrary, these ideas have been tried with more or less success in the past. The principal characteristic of the design is a careful balancing of parts for the specific purpose of permitting that close chemical control, without which continuity of operation, uniformity in quality and quantity of product, and the highest efficiency and economy are impossible.

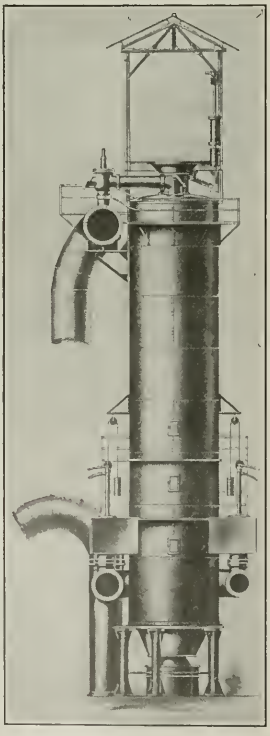
It may be assumed, without question, that uniformity in output presupposes a similar condition as regards input, and that the former cannot be safely predicated on variable conditions as regards the latter. Therefore, in addition to certain essential conditions, already indicated, we should specify stone of uniform size within prescribed limits, clean and free from dirt, and charged in predetermined quantities at regular intervals; close regulation of the draft, and quality of the exit gases and their temperature; also close attention to regulation of the temperature in the reaction zone.

[2]Geological Survey of Ohio Bulletins 4 and 5, Orton & Peppel.

For the purpose of description the kiln may be divided into three sections or zones, cooling, reaction and preheating. At the bottom of the cooling zone is located the continuous discharging mechanism, and at the top of the zone the inlet tuyeres, admitting the fuel gas from the producers to the reaction zone. The design of the tuyeres is important in order that a uniform distribution of the fuel gas may be insured throughout the mass in the reaction zone; otherwise, there would be a tendency for the gas to creep up the sides of the kiln, causing over-burning at the sides and under-burning or core in the center.

The reaction zone is encircled with three rows of peep-holes for observation. The couple of the recording pyrometer is located in the middle belt. The boundary line between the reaction and preheating zones is not, of course, very sharply defined, but it may be roughly assumed that the preheating zone is comprised within the limits of the upper half of the kiln, and the reaction zone the fourth next below.

Gas is admitted from the producers to the reaction zone through water-cooled balanced valves, easily regulated from the ground, where are located the temperature gages for each kiln. The continuous discharge mechanism at each kiln is driven from a common shaft, but can be stopped or started independently of the balance of the kilns in the battery. The speed of discharge is figured to 25 tons of lime per day of 24 hours, though means are provided for varying the speed of the common driving shaft. The top of the kiln is closed, and in the cover is located a hopper and charging belt, the latter raised and lowered by compressed air, and designed to give a uniform distribution of the stone over the top of the kiln, maintaining the surface level at all times, insuring an even distribution of the gases in the preheating zone. At the top of the kiln is also located the draft pipe for the exit gas, regulated by a valve of the same type as that used for the fuel gas.



GAS-FIRED CONTINUOUS KILN

The total height of the kiln to the level of the charging floor is 60 feet, and from the bottom of the cooling zone to the top of the preheating zone 48 feet. The diameter is 8 feet, maximum, inside the brick work. The stone is charged in uniform batches of 1000 pounds at regular intervals of 15 minutes, or 4 periods per hour, for a capacity of 25 tons per day. The draw is continuous, and can be arranged at any section of the bottom circumference where most convenient. The cold lime is removed in barrows or conveyors, for hydrating, storage, or direct to cars for shipment.

The preferred arrangement of the kilns is in batteries of six, with a producer-gas machine located midway of the battery. This combination, under proper control, will have a capacity of 150 tons of lime per day, with a coal to lime ratio of 1 to 5 or 6, depending on the quality of the coal. Four kilns of this type have been in constant service at the plant of the Farnam Cheshire Lime Company, Farnam, Mass., for a period of over five years, and are reported to have given satisfactory results in economy of operation, capacity and quality of product.

Roanoke, Va.

Strength of Commercial Liquid Glues

Most of the commercial liquid glues are manufactured from the skins, heads and swimming bladders of fish. Others are made by special treatment of the glue extracted from the hides, skins and bones of cattle; some for special uses are prepared from starch, from various natural gums, or from casein.

At the Forest Products Laboratory tests were made on a number of these liquid glues by B. A. P. inspectors, who found that they differ widely in strength. Some of them are so weak as to be entirely unsuitable for woodworking purposes, while others compare favorably in strength with the "hot" glues. The adhesive strength of the glues tested varied from less than 50 lb. per sq.in. to more than 3000 lb. per square inch.

Liquid glues may be tested by gluing together pairs of specially selected hard maple blocks, placing them in a testing machine, and measuring the force required to shear them apart. About 300 specimens, representing 26 different glues, have been tested in this way at the laboratory. According to the data thus obtained, a high grade liquid glue should have an average shearing strength of not less than 1700 or 1800 lb. per square inch.

In addition to uniform high adhesive strength, it is evident that certain other characteristics are desirable in a liquid glue. When spread upon wood surfaces, it should "set" and dry rapidly. In its container, it should remain fluid and workable at all ordinary temperatures. It should be elastic and shock-resistant. It should not be unusually susceptible to the action of high temperatures, high humidity, molds and bacteria.

The study gave evidence that the strength of liquid glue, like that of "hot" glue, depends largely upon its "body," or thickness, or, strictly speaking, upon its viscosity. Of 11 liquid glues examined, the thickest or most viscous glues showed the greatest adhesive strength.

German-Owned Shares Sold

The German-owned shares of the capital stock of the American Metal Co., Ltd., were sold at public auction by the Alien Property Custodian on April 7. Hayden, Stone & Co. of 25 Broadway, New York City, bought 36,344 shares for $4,850,160, while 562 shares of capital stock of the Compania de Minerales y Metals, a subsidiary company, were sold to Mr. H. W. McAnteer of the American Metal Co. for $57,000. Since none but American-owned companies were allowed to bid, 76 per cent of the stock is now in American hands.

Recent Chemical and Metallurgical Patents

Nitrogen Fixation

Nitrogen From Air.—Ammonia from cyanamide is combined with sulphur dioxide and water to give a concentrated solution of ammonium sulphite. When this is treated with air on the counter current principle, the oxygen converts the sulphite into sulphate, and by arranging the absorption towers in series, the oxygen is almost completely absorbed at a temperature of 70 to 75 deg. C. In this manner NOBILE TOMMASI of Basel, Switzerland, obtains a supply of pure nitrogen for the further production of cyanamide; 48.3 kilos of ammonium sulphite, containing 11.7 kilos of nitrogen, absorb 6.7 kilos of oxygen. The residual nitrogen, 22.4 kilos, is nearly twice that required to produce 48.3 kilos of ammonium sulphite additional, and is consequently sufficient to cover any losses in the manufacture of cyanamide, (1,295,635; Feb. 25, 1919; assigned to Usines Electriques de la Lonza of Gampel, Switzerland).

Separation of Alkali-Metal Cyanide From Hydroxide.—Alkali-metal cyanide made by passing nitrogen over a heated mixture of sodium or potassium carbonate and coke or charcoal is always contaminated with the oxide or hydroxide of the metal used. FLOYD J. METZGER of New York adds to this mixture sufficient water to convert any unchanged anhydrous carbonate into the decahydrate. A "treating solution" consisting of a water solution of ethyl, methyl or denatured alcohol, acetone or a similar solvent is used to dissolve the cyanide and hydroxide, the hydrated carbonate being insoluble in the mixture. By passing carbon dioxide into the resulting solution, the hydroxide is converted into carbonate, which separates out as the decahydrate. The filtered solution, after evaporation in a solvent recovery apparatus, yields pure alkali-metal cyanide in a dry state. (1,295,049; Feb. 18, 1919; assigned to Air Reduction Co.)

Ammonia From Alkali Cyanide and Ferrocyanide.—Cyanides are decomposed by steam according to the equation:

$$NaCN + 2H_2O = HCO_2Na + NH_3$$

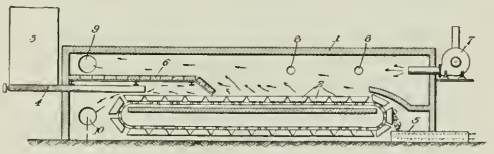
When, however, cyanide resulting from the process of fusing a carbonate with charcoal and iron is used, the yield of ammonia is poor. C. F. BIERBAUER of Kenvil and L. S. FINCH of Dover, N. J., dissolve the crude cyanide as rapidly as possible by blowing the powdered material into a tank equipped with a water spray and agitator. The solution is immediately filtered on a continuous rotary filter. In this manner the formation of ferrocyanide is reduced to a minimum. The solution is heated indirectly by steam at 125-lb. pressure in a tank provided with pressure relief valve which is set to operate at 50-lb. pressure. Pressure in the tank is thus maintained at 50 lb. while the ammonia and water vapors which pass through the relief valve are condensed, a portion of the water condensed being returned to the tank so that the final product is a concentrated ammonia solution. When the crude material contains an appreciable amount of ferrocyanide, the cyanide present is changed into ferrocyanide by digesting with finely divided iron, and the whole decomposed, after filtering, in a similar apparatus using from 80 to 150 lb. pressure. (It would seem as though the mixture could be treated without the conversion of cyanide to ferrocyanide, by first decomposing the cyanide at 50-lb. pressure and subsequently increasing the pressure by means of the relief valve, so that the ferrocyanide would be decomposed.) (1,295,262 and 1,295,293; assigned to the Hercules Powder Co.)

Nitric Acid From Ammonia.—Although ammonia will not burn in air even in the presence of a catalyzer, unless the latter is heated to from 600 to 700 deg. C., WALTER S. LANDIS of New York has found that with air so enriched as to contain 30 to 40 per cent oxygen, external heating of the catalyzers is unnecessary, and the reaction proceeds according to the equation:

$$4NH_3 + 5O_2 = 4NO + 6H_2O.$$

The nitric oxide is converted into nitric acid by known methods. The necessary oxygen may be obtained from liquid air, and the nitrogen used to make cyanamide as the source of ammonia. (1,292,814; Jan. 28, 1919; assigned to Frank S. Washburn.)

Manufacture of Calcium Carbide.—A method for producing aggregates to be used as the charge in calcium carbide furnaces was patented by FREDERICK M. BECKET of Niagara Falls on April 27, 1915 (1,137,567). Lime was mixed with bituminous coal and the aggregates formed in a by-product coke oven of the



METHOD OF PREPARING CHARGE FOR CALCIUM CARBIDE FURNACE

ordinary type. His present inventions deal with a special type of furnace, in which heat losses are reduced to a minimum by burning the limestone and coking the mixture in a single operation. The hot gases from the limestone give the heat necessary for the coking operation, while the volatile products from the latter, after passing through a by-product plant, are used as part of the fuel for burning the limestone. A mixture of $\frac{1}{8}$-in. grains of limestone and rich bituminous coal, in the approximate proportions of 100 to 62, is fed from the storage bin 3, by means of a mechanical device 4, into the cars 2, which form a continuous chain. The furnace is heated by the burners 7, 8, but during the first stage of the passage through the furnace, the material is protected from the direct action of the flame by apron 6. As a result, the coking operation is practically completed during this period, the volatile products escaping through opening 10, to be used as indicated above. In the open portion of the furnace, the limestone is converted into lime, without, however, injuring the aggregates already formed. The fully converted charge is conveyed, by means of 5, to the carbide furnaces with as little loss of heat as is practicable. (1,292,386 and 1,292,387; Jan. 21, 1919; assigned to Union Carbide Co.)

Hydrometallurgy of Copper.—Fig. 1 represents a flow sheet of a process devised by W. N. ROSSBERG and A. E. SHERIDAN of Butte, Mont., for the recovery of copper from sulphate solution. This solution should be free of considerable quantities of iron before entering the absorption tower. This may be done by air agitation with copper oxide and then filtering. Precipitation by H_2S as cuprous sulphide requires but half the amount of reagent necessary otherwise, and while effected at atmospheric temperature and pressure, is considerably facilitated at 160 deg. F. and 40 lb. per sq.in. The reactions are complicated and not determined; but may be summed to

$$2\ CuSO_4 + H_2SO_3 + H_2S + H_2O = Cu_2S + 3H_2SO_4$$

Thus acid is generated as well as recovered. The prepitation may also be effected by adding powdered CaS to a solution previously saturated by SO_2 as follows:

$$CaS + 2CuSO_4 + H_2SO_3 + H_2O = Cu_2S + CaSO_4 + 2H_2CO_4$$

which reaction is also facilitated by heat, pressure, agitation and free acid. The patentees point out that this process can be utilized to purify zinc sulphate

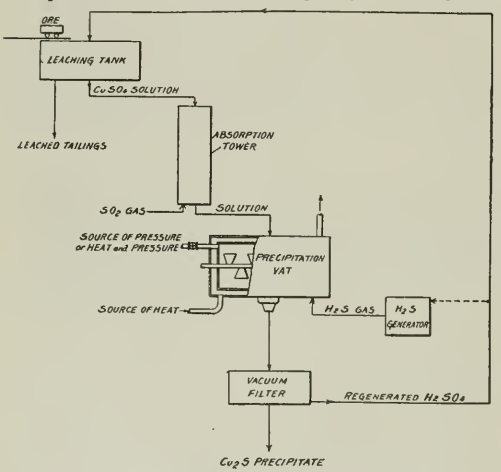


FIG. 1. FLOW SHEET OF PROCESS FOR RECOVERY OF COPPER FROM SULPHATE SOLUTION

solutions from metals of the second group. Its advantages are that it generates acid, requires a minimum of H_2S, gives a high-copper precipitate, and gives a final solution substantially free from H_2S, any excess being neutralized by the SO_2 present. (1,292,075; Jan. 21, 1919.)

Manganese Dioxide Depolarizers.—While pyrolusite, or natural manganese dioxide, is used as a depolarizer in large batteries of the Leclanché type, the artificial product is more efficient for small dry batteries, especially those used in flashlights. For the preparation of the latter, two reactions have been used:

$$Mn(NO_3)_2 + MnO_2 + 2NO_2 \qquad (170°\ C.)$$
$$2MnCO_3 + O_2 = 2MnO_2 + 2CO_2 \qquad (300°\ C.)$$

The low melting point of manganese nitrate causes the product of the first reaction to appear in the form of a hard solid mass, which, even after grinding, is inferior to the powdered mineral. The second reaction does not go to completion and the carbonate remaining impairs the shelf life of the cell. By combining the two methods, MORDUCH L. KAPLAN of Brooklyn overcomes these difficulties. Manganese carbonate is heated above 300 deg. C. for several hours, yielding a product containing approximately 70 per cent MnO_2. Treatment with nitric acid converts the unchanged carbonate and acid-soluble impurities into nitrates. The mixture is heated to the temperature at which the $Mn(NO_3)_2$ decomposes. The nitrates formed from the impurities are stable at this temperature and are removed from the final product by extraction with water. (1,293,461; Feb. 4, 1919.)

ALFRED A. WELLS of Montclair, N. J., prepares a carbide of manganese by heating pyrolusite and coke together in an electric furnace. The iron carbon formed simultaneously is not readily decomposed by water, while the Mn_3C is converted into a flocculent hydrate $(MnO_2H_2)_2$, which may be separated from the heavier undecomposed carbides by floating. Upon oxidizing the hydrate in aqueous suspension by ozone, or a mixture of air and ozone, a very efficient variety of manganese dioxide results, which is considered to be either a polymerized form, or a cyclic modification.

$$3MnO_2 + 7C = Mn_3C + 6CO$$
$$Mn_3C + 6H_2O = (MnO_2H_2)_3 + CH_4 + H_2$$
$$2(MnO_2H_2)_3 + 3O_2 = 2Mn_3O_8 + 6H_2O$$

(1,293, 272; Feb. 4, 1919; assigned, by mesne assignments, to National Carbon Co.)

By-Products From Iron Blast-Furnaces.—H. B. WEAVER and JAMES GAYLEY of New York note that volatile potassium cyanide and carbonate, together with a much smaller amount of sodium compounds, may be withdrawn from the bosh of an iron blast-furnace through suitable openings near the tuyere zone and condensed in quantities sufficient to make the process commercially feasible. The patentees think that these compounds are formed at the focus, and exist unchanged for a certain distance up the bosh in the hot reducing atmosphere, but there break up, and the basic portion is largely condensed and returned. In this manner, a zone of high-alkali volatiles exists, being continually renewed by the descending charge, and bled mostly by the formation of slag. It can, however, be abstracted either continuously or intermittently as noted, care being taken to withdraw a quantity of gas which carries less heat than the normal excess of hearth over shaft heat. This is controlled by frequent test slag-taps—dark slag immediately indicates improper working and slagging of iron due to excessive withdrawals of heated gas. (1,292,937; Jan. 28, 1919.)

Concentrating System.—RUDOLF GAHL of Denver, Colo., notes that in either water or flotation concentration the middling product is difficult to handle owing partly to the accumulation of altered or partly decomposed minerals. At other times tailings (particularly from flotation machines) contain considerable amounts of unrecoverable oxidized minerals. He therefore patents the process of producing a clean concentrate, then roasting the deslimed middling and leaching it by suitable reagents either alone or in conjunction with the tailings, and finally recovering valuable metals in solution by electrodeposition or otherwise. (1,291,824, Jan. 21, 1919.)

Synopsis of Recent Chemical and Metallurgical Literature

Metallurgical Practice.—H. L. CAMPBELL, metallurgist of the Industrial Works, Bay City, Mich., which specializes on locomotive cranes, has given a paper before the Steel Treating Research Society, which is published in their *Proceedings*. In it he presents the accompanying tabulation of physical and chemical properties specified for various crane parts, together with the directions for heat treatment.

TABLE I. PHYSICAL SPECIFICATIONS OF METALS

Material	Heat Treatment	Tensile Strength	Elastic Limit	Elongation per Cent.	Reduction, per Cent.	Sclerscope No.
Hammered steel, C 0.30 to 0.40 per cent	. .	65,000	30,000	36	52	22
Hammered steel, C 0.30 to 0.40 per cent	R.	90,000	60,000	25	50	30
Hammered steel, C 0.20 to 0.30 per cent	...	63,000	30,000	35	50	20
Hammered steel, C 0.20 to 0.30 per cent	R.	80,000	45,000	30	50	27
Hammered steel forged, C 0.20 to 0.35 per cent	R.	101,000	62,500	21	34	33
Hot rolled steel shafting, C 0.25 to 0.35 per cent	...	60,000	26,000	40	50	19
Hot rolled steel shafting, C 0.25 to 0.35 per cent	R.	65,000	35,000	35	55	22
Hot rolled steel rectangular bars, C 0.25 to 0.35 per cent	...	50,000	30,000	40	70	15
Hammered steel (forged aa keys), C 0.20 to 0.30 per cent	.	100,000	90,000	20	38	46
Trojan steel, C 0.40, Cr 1.00, Ni 2.00	...	120,000	95,000	18	50	30
Swedish iron	...	50,000	30,000	30	40	16

Gray cast iron	3,200 Pounds, transverse breaking load on 1½-in. bar with 12 in. between supports.					
Gray cast iron	20,000 Pounds, tensile strength per sq.in.					
Gray cast iron	100,000 Pounds, compressive strength per sq.in.					
12 per cent semi-steel	3,000 Pounds, transverse breaking load on 1-in. square bar with 12 in. between supports.					
12 per cent semi-steel	20,000 Pounds, tensile strength per sq. in.					
30 per cent semi-steel	3,500 Pounds, transverse breaking load on 1-in. square bar with 12 in. between supports.					
30 per cent semi-steel	30,000 Pounds, tensile strength per sq.in.					

TABLE II. CHEMICAL SPECIFICATIONS

	C	Si	Mn	S	P
Cast vanadium steel	0.30	0.27	0.80	<0.03	<0.05
Cast carbon steel	0.24 to 0.32	0.25 to 0.30	0.65 to 0.80	<0.08	<0.06
Gray cast iron	1.6 to 1.9	0.5 to 0.9	0.06 to 0.08		<0.50
12 per cent semi-steel	1.8 to 2.25	0.95 to 1.0	0.04 to 0.06		<0.50
30 per cent semi-steel	1.4 to 1.5	0.95 to 1.0		<0.05	<0.30

Heat treatments are as follows:

E. Heat to 1600 deg. F. and hold for 30 min.; cool in air for 10 min.; replace and cool in furnace, leaving door open until temperature is below 1300 deg. F. For mud rings, and door rings.

F. Heat to 1600 deg. F. and hold for 60 min.; cool in air to below red heat; reheat to 1250 deg. F. and hold for 90 min.; cool in furnace. For large castings to produce maximum softness with fine grain.

J. First heat: Heat to 1800 deg. F. and hold for 2 hr.; cool in air. Roughing cuts. Second heat: Heat to 1200 deg F. and hold for 3 hr., cool in furnace. Finish machining. For vanadium steel jack-beams.

P. Heat to 1800 deg. F. and hold for 60 min., cool in air to below red heat; reheat to 950 deg. F. and hold for 90 min., cool in furnace. For vanadium steel castings.

L. Heat to 1600 deg. F. and hold for 60 min.; quench in water and remove while warm; reheat to 750 deg. F. and hold for 90 min., cool in furnace. For roller pins and parts of maximum hardness.

K. Heat to 1600 deg. F. and hold for 60 min.; quench in oil and remove while warm; reheat to 900 deg. F. and hold for 90 min., cool in furnace. For gearing.

R. Heat to 1600 deg. F. and hold for 60 min., quench in water and remove while warm; reheat to 900 deg. F. and hold for 90 min., cool in furnace. For hammered or rolled shafting and castings.

This company makes its own alloy steel by addition to converter metal. Sixteen pounds of 35 per cent ferrovanadium and 18 lb. 80 per cent ferromanganese per ton of steel are preheated in the ladles; 10 lb. 50 per cent ferrosilicon is added during pouring from converter.

Rupture of Cast Iron in Contact With Mixed Acid.—In a paper read before the Edinburgh section of the Society of Chemical Industry, A. C. CUMMINGS of the Lothian Chemical Co., Ltd., called attention to the possible dangers arising from the use of cast-iron apparatus with nitric or fuming sulphuric acid. (*Journal* Soc. Chem. Ind., Feb. 15, 1919, p. 31T). In connection with the manufacture of TNT, this company used cast-iron acid eggs for handling the mixed acid, which consisted of 50 per cent nitric acid, 45 per cent of sulphuric acid and 5 per cent of water. About two years ago, two of these eggs burst while blowing was in progress, with serious results. The dimensions of the eggs were as follows, those of the second egg being in parentheses: Internal diameter, 4 ft. (6 ft.); depth, 4 ft. 9 in. (6 ft.); average thickness of walls, 1 in. (1½ in.). The air pressure was normally much lower than the maximum of 60 lb. per sq.in. In bursting, the egg appeared to fall in rather than to be blown out.

Examination of pieces of the iron showed that corrosion was practically negligible. Furthermore, the tensile strength of the iron from the inner surface was still equal to that of the original iron, consequently the egg should have been able to resist a pressure many times greater than that actually employed. However, on breaking a washed piece of the iron, the odor of acid was noticeable, and after two days the inner half of the fracture was badly rusted. Photomicrographs showed graphitic plates of large size which formed "nests" near the surface of the iron, making a coarse or open structure. As a result, acid had actually penetrated to a depth of about one-third of the thickness and in many places small masses of crystallized iron salts could be seen in the interior.

The action of fuming sulphuric acid on cast iron was observed by R. KNIETSCH (Ber., 1901, 34, 4090), who gives the following explanation:

"This remarkable phenomenon is caused by oleum diffusing into the pores of the cast iron, and there be-

ginning its work of destruction, inasmuch as it is converted into sulphur dioxide and hydrogen sulphide by the reducing action of the iron, and may even give rise to carbon dioxide from the carbon in the iron. All of these substances are gases with comparatively low critical temperature, and consequently cause high pressure in the interior of the cast iron. If such a piece of iron is broken, the presence of sulphur dioxide and hydrogen sulphide may be recognized by the smell and the evolution of gas when it is immersed in a suitable fluid."

MR. CUMMINGS' theory is that the disruption is due to the expansive force of the crystals of iron salts growing in the interior of the metal. Examination of some cast-iron measuring pots which had been used for mixed acids, but had never been under pressure, showed the presence of cracks of a similar nature. This would tend to substantiate the crystallization theory.

Regardless of theory, the fact remains that the penetration of the acid into the surface of the casting is the initial factor in the disruption of the apparatus. It would thus appear that the aim of manufacturers of cast-iron apparatus for use with nitric or fuming sulphuric acid should be to avoid as far as possible an open structure which would permit the acid to penetrate into the interior of the iron.

Purifying Paraffine Wax.—In the *Engineer*, Feb. 14, 1919, a description is given of a process devised by R. S. DICKIE, which is an improvement on the sweating process for refining paraffine. It is applicable to hard, middle or soft scale, or a mixture of all three. The material to be treated is melted at as low a temperature as possible and is then pumped through a spraying nozzle, in which a blast of cold air atomizes and at the same time chills the scale. The temperature of the material issuing from the nozzle is 5 to 10 deg. F. below the melting point of the scale. At this temperature, the particles of wax solidify, while the oil and low melting point paraffines remain liquid. The atomized mass passes into a rapidly revolving drum formed of fine mesh wire cloth. The liquid portion of the mass is separated from the yellow wax by centrifugal force, and is collected in an annular trough surrounding the drum. From one to three minutes suffices for the separation of the heavy oil. The residue of yellow wax is removed by heating the drum electrically to 140 deg. F., the melted wax being collected in a second annular trough.

Specific Heats of Silicates and Platinum.—WALTER P. WHITE of the Geophysical Laboratory has published a second series of specific heats of silicates in the *American Journal of Science*, 47, 1 (1919), and also a determination of the specific heat of platinum at high temperatures, using the same apparatus, in the *Physical Review*, 12, 436 (1918). The results for platinum up to 1300 deg. C. are thought to be accurate to within 3 per mille, and the increase of the specific heat at constant pressure with rise in temperature is so nearly linear that the following equations hold:

True specific heat $= 0.031686 + 0.000064$ deg. C.

Atomic heat, $A_p = 6.185 + 0.00125$ deg. C.

There is no reason to suppose that this specific heat at constant pressure really varies linearly, since the work of expansion does not; yet it gives a simple expression well within the accuracy of the experimental data. The specific heat at constant volume cannot be determined experimentally, but may be calculated from the values for constant pressure. The figures for several temperatures are as follows:

Deg.	A_v
500	6.447
900	6.678
1300	6.844

It will be noticed that A_v increases regularly with advancing temperature and, also, that it is above the value 5.96 indicated by the accepted kinetic theories of the solid state and Delong and Petit's law (as modified by G. N. Lewis *et al.*).

Micrometer With Pressure Attachment

A CONVENIENT instrument for testing the properties of rubber, felts, etc., used for packing, gaskets and various compressibles has recently been put on the market by S. W. Widney of Chicago.

The resiliometer is, in effect, the combination of a direct reading dial type micrometer gage with a reaction device whereby both the compressibility and the rebound after compression (otherwise known as the resilience) of the material can be determined positively. The readings are simple, and therefore easily understood.

The resiliometer gives the following information in direct readings:

Thickness (normal), in thousandths of an inch (first standardized method).

Hardness, i.e., the precise extent to which a material gives as the result of a standard pressure (first standardized method).

Resilience, i.e., the rebound—the capacity to recover from compression after the load is released. Resilience is a quality not fully understood by many large users of felt, rubber, leather, paper, cork, textiles and other compressible materials, as not infrequently the resilience is estimated in excess of the load applied. This is impossible because compression, while it may destroy energy, cannot create it. Therefore, the maximum resilience is the amount of the load.

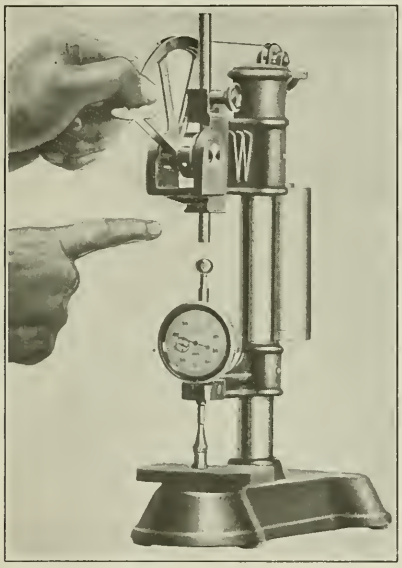
As will be seen by a glance at the illustration, the instrument consists primarily of a dial underneath which is a presser-foot touching a perfectly level base on which the material is supported. Making sure that the quadrant which holds the weight descending from it is drawn up and held by the spring-catch, the operator lifts up the presser-foot and inserts the material which is to be gaged and tested.

The large dial is graduated in 100 divisions of 1/1000 in., so that one revolution of the large pointer or hand is equivalent to an elevation of 0.1 in. To count tenth-inch increments a small dial indicates the number of revolutions of the counter or hand. Suppose the material to be tested is 0.100 in. thick, then as the presser-foot goes down, the hand stops at the 100th gradation.

Release the spring-catch holding the weight and allow the weight quadrant to swing back until pressure is put on upper end of presser-foot at the top of dial. As weight is released, the plunger, which is connected with the quadrant, forces the presser-foot to sink into the material, thereby diminishing its thickness. When the presser-foot reaches the limit of compression with the weight applied, the reading on the dial at that time is taken and compared with the normal or original reading. For instance:

Normal thickness reading.....	0.100 in.
Reading under pressure.....	0.050 in.

These readings are interpreted that goods of a normal thickness of 0.100 in, showing under pressure a thickness of 0.050 in., are 50/100 hard. The material is arbitrarily called 50 per cent hard. If it had not been compressed at all its hardness would have been 100 per cent (an impossibility with any resilient material). If it had compressed to one-fourth its original thickness, its hardness would have been 25 per cent. If it had compressed to one-tenth of its original thickness, it would



MICROMETER WITH PRESSURE ATTACHMENT

have been 10 per cent hard, and so on. This gives us the hardness figure of the material in question—a figure henceforth fixed in comformity with the Widney standard.

As soon as the reading has been taken, pull the quadrant back, releasing weight pressure on the presser-foot. The hand on the dial will begin to advance again. When weight is raised a sufficient height so that the weight pressure is released from the presser-foot, immediately note the reading of the dial hand. This reading should be taken as weight pressure is released, thereby ascertaining the instant comeback or rebound and not the gradual return.

For example if the dial-hand (which was at 50 under pressure) advances as pressure is released till it reached 0.080 in., the rebound is 60 per cent. For 80 — 50 = 30 and 30 is $\frac{3}{5}$ of 50 = 60 per cent. Had the material tested immediately resumed its original thickness, the rebound would then be 100 per cent. The ratio of the distance of rebound to the distance of compression is the percentage of rebound.

The capacity of a material to rebound after the load is released is often confused with the resilience. However, a distant rebound is not the true measure of resilience. Bear in mind that resilience is the capacity which the material has for giving back energy given it during the loading process. The only existing means of ascertaining the amount of this energy is by the resiliometer method—applying successive increments of load, plotting the increment line, and removing the load in successive decrements, plotting the decrement line. Between these two lines is the hysteresis or energy load. The area back of the line indicates the amount of energy recovered after the load is released.

Resilience also is sometimes confused with elasticity, which is the capacity of material to distend or reflect, as illustrated by the action of a rubber band after being stretched beyond its normal position or the reaction of a steel bar after being bent out of its original or normal position.

Logically, the resilience of any compressible material is determined by its capacity to recover from compression after the load is removed.

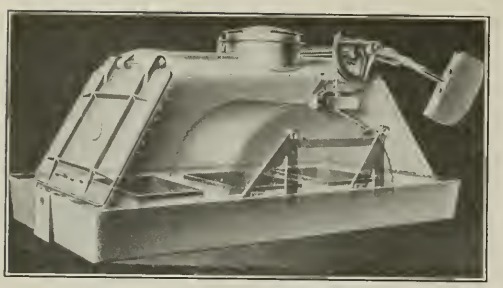
Gas Reversing Valve

IN THE operation of any gas-fired furnace, it is highly desirable that the valve controlling the direction of the flow of gas shall operate rapidly and easily. These factors have been kept in mind in designing the new W-S-M gas reversing valve which has just been placed upon the market by the Wellman-Seaver-Morgan Co. of Cleveland, Ohio. That the conditions have been met is evidenced by the fact that a 36-in. hand-operated valve can be reversed in from 3 to 7½ sec. with a pressure of not more than 25 lb. This is accomplished by a balanced hood and counterweights. An equally important feature is that the operating mechanism is outside of the casing, where it is easily accessible and always cool.

The center port is connected to the chimney. Waste gases from the furnace flow from whichever outside port the hood is covering to the chimney port. This leaves a clear passage for the fuel gas or the air entering the casing through the mushroom valve at the top to pass through the third port to the furnace regenerator. Reversal of the flow of gas or air is accomplished by moving the hood to a position over the center port and the one previously uncovered.

The base of the valve is a cast iron rectangular pan with three walled circular openings or ports. The hood which covers the center and one end port is semi-elliptic in form and made of steel plates with angles at the bottom to support a fire-brick lining. The base pan holds a quantity of water so that when the hood is over the ports a water seal is formed to prevent the escape of gas. The base pan has a tapped hole at each end for a water pipe. There is a perforated strainer at the intake end and a dam plate at the other end to hold the water at such level as to allow the hood to extend 3 in. into the water forming the seal.

The outer casing is made of steel plate and lined with fire brick. It has cast iron door frames and door at each end through which the hood may be removed or inserted. Each door has a small peekhole with a swinging cover which enables inspection at any time. On the top of the casing is a cast iron neck which connects either with the fuel gas flue or the air intake, depending upon the purpose for which the valve is used. The hood is moved by a series of levers and coupling shafts which extend through the water under the casing and into sockets on the hood. The shafts move on chilled iron bearings. The following advantages are claimed for this valve:



NEW DESIGN OF A GAS REVERSING VALVE

The semi-elliptical form of the hood allows free flow of the gas, as there are no abrupt turns or constricted areas in the passage formed by the ports and hood. This feature is very important in obtaining maximum efficiency from the stack draft.

All leakage or waste of gas is prevented by the water seal. Such a seal does away with all packing, tightening and adjusting, the only attention required being the flow of a small quantity of water into the bed plate to replace the amount evaporated.

Due to its compactness, the valve requires comparatively little floor space and adapts itself to various arrangements of flues from the regenerators to the stack.

The weight of the hood is counterbalanced by the weights of the lever arm in such a way that the hood is in balance at any position, so to move the hood it is only necessary to exert enough force to overcome friction. This is an important feature in hand-operated valves.

New Type of Portable Arc Welder

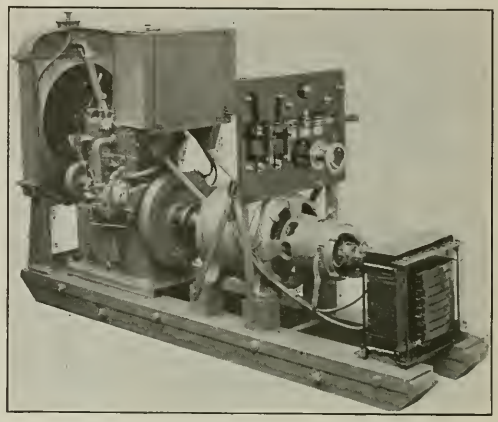
ALTHOUGH electric arc welding has been used for several years in the iron and steel industry, its use has mostly been confined to factories, repair shops and other locations where the work can be brought to the machine. The accompanying illustration, however, shows a new type of portable arc welder, which presents especially interesting features and is designed for operation where electric current is not available.

It consists of a Lincoln Electric Co. 150-amp. arc welding generator direct connected to a Winton G. L. 5-gasoline engine, and is intended for mounting on an automobile truck or other convenient position so that it may be transferred from place to place. An interesting point in its construction is the method adopted to insure a steady arc and a constant and readily controllable heat—the two greatest difficulties met with in the design of this class of apparatus.

The volts required to maintain a welding arc vary from 50 down to as low as 15 volts (where a metal electrode is used). The plan adopted by most makers to render the arc steady is to introduce sufficient "ballast resistance" in series with the arc to prevent excessive current being taken when the operator short-circuits the generator on "striking the arc." This method is exceedingly wasteful, more than three-quarters of the power generated being absorbed in the ballast resistance itself.

This arc welder uses a compound-wound generator, the series windings of which are connected up so as to oppose the shunt field, and the two windings are so proportioned that the voltage decreases in the same ratio as the current increases, thus limiting the short circuit current. Another important effect of this is that the horsepower, and therefore the heat, developed for a given setting of the regulator switch (shown on the control board above the generator) remains practically constant.

It is asserted that a kilowatt-hour can be made to do four or five times as much work with this



PORTABLE ELECTRIC ARC WELDER

welder than with machines using ballast resistance. Additional arc stability is also insured by the stabilizer (seen at the extreme right of the picture). This is a highly inductive low resistance coil connected in the welding circuit. It serves to correct momentary fluctuations of current in much the same manner as the flywheel of an engine produces an even turning speed.

Pyrometer for Brass and Bronze

THE importance of the pouring temperatures in the manufacture of brass and bronze castings is so well recognized that comment on that fact is hardly necessary. Wrong temperatures are probably the chief cause of faulty castings. This factor not only enters into the production of the casting itself, but the properties of the finished article are also affected.

The chief difficulty of measuring the temperature by use of the ordinary thermo-electric pyrometer has been the lack of a suitable protection tube for the thermocouple. There is a limit to the thickness of the tube wall which is permissible because of the necessity of a quick reading. The tube has to be of relatively thin walls, but at the same time it must successfully withstand the action of the molten material. Refractory tubes are not satisfactory because they are too fragile to stand ordinary foundry use, and are very apt to break under the sudden temperature changes encountered.

An alloy has been developed, however, by the Hoskins Manufacturing Co., Detroit, Mich., from which a satisfactory protection tube can be made. Fig. 1 illustrates how the equipment is used. The tube consists of three parts, as shown in Fig. 2. Section *B* telescopes into the upper end of the seamless steel tube *D*, and the

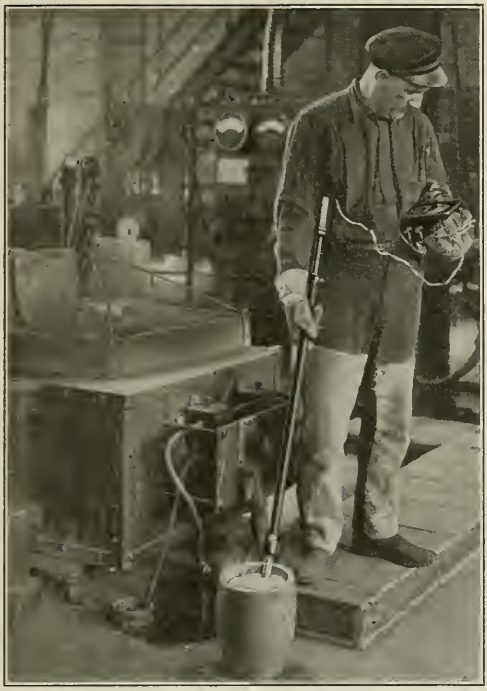


FIG. 1. READING THE PYROMETER

protection tube proper, marked *C*, is held in the lower end. This tube is 10 in. long and is made of the new alloy chromon; it is that part of the entire tube which is inserted into the metal. The thermocouple *A* is entirely encased in the tube and can be easily renewed.

The alloy tip and the thermocouple are the only parts which require renewal. When the molten metal ultimately destroys the alloy tube, it can readily be removed and a new one installed. A shoulder is cast on the upper end of the tip and this engages in the collar shown on the tube *D*, being held in place by giving it a half turn and packing the connection with a special refractory cement.

If the tube is used to complete destruction or to a point where the molten metal can reach the thermocouple, of course the latter has to be repaired. This can be done by merely cutting off the damaged part, and then twist and re-weld the wires. This procedure can be repeated until the couple reaches a length of 3½ ft., when it must be renewed. The couple can be changed end for end; that is, the unwelded end can be welded and used as the hot end. It is not necessary to re-calibrate the couple after re-welding it.

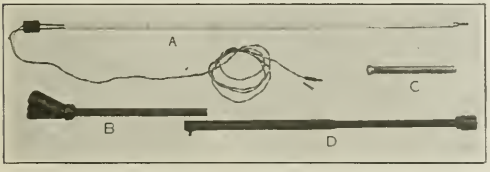

FIG. 2. PYROMETER FOR BRASS AND BRONZE

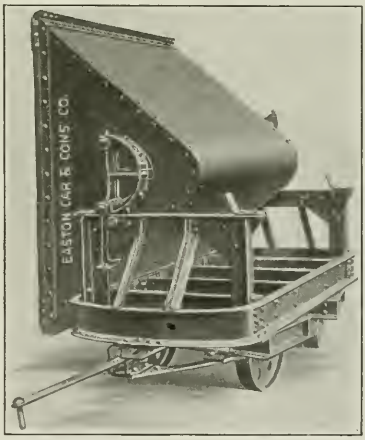
Trackless Trailer With Dump Car Body

THE increasing use of industrial tractors has created an unusual demand for all kinds of trailers. To meet the demand for a car that would not only admit of easy trailing but would also speed up loading and unloading of loose materials the new Easton car here shown was developed.

It is a four-wheel steer trailer that will run over cement, wood, composition or any kind of flooring. In fact, it will even run quite smoothly over rough ground when supplied with extra large wheels. All wheels are equipped with roller bearings and may be furnished with rubber or composition tires. Close tracking of trains of these cars is accomplished with comparative ease because both front and rear trucks of each trailer swivel. Trains of six cars will track within three inches and will take a curve of 8-ft. radius or smaller.

The body of the trailer is distinctive and possesses many features that make for economy and speed in loading and unloading coal, ashes, sand, ore, slag,



TRACKLESS TRAILER WITH DUMP CAR BODY

refuse and practically every kind of bulk material. Some of the more important features include: Special latch for locking the body in a half-dumped position, thus lowering the loading height for hand loading; automatic safety latches; extra heavy body that dumps clear of the wheels, the only type that will so dump (45 deg. angle of dump); cast-steel rockers and extra heavy underframes.

The car is built by the Easton Car & Construction Co. of Easton, Pa.

Italian Import Restrictions

The following commodities may now be imported into Italy by private importers when import licenses have been obtained covering such shipments. Formerly these commodities were among those which private importers might not import into Italy: Acetate of lime; acetone; alcohol; benzol; toluol; naphthaline; vegetable and animal tallow; leather; jute; wool, and cotton linters.

Book Reviews

A HANDBOOK OF PHYSICAL MEASUREMENTS. By *Ervin S. Ferry*. Two volumes. Price $2.00 each; 234 pages, including the index; illus. New York: John Wiley & Sons, Inc.

The author of this work has followed the plan of presenting at length the theory of the experiments and the derivation of the formulæ required in each division of the subject before giving descriptions of apparatus to be used and directions for the actual manipulations necessary in performing the experiments. The exposition of the theory is as brief and concise as is consistent with the author's purpose as indicated by his statement, "It is rare that an experiment should be performed before the student understands the theory involved and the derivation of the desired formulæ."

The first volume contains three chapters, the first being an introductory chapter upon physical measurements in general. Chapter 2, after a discussion of the theory and methods of fundamental measurements, gives detailed directions for 25 experiments upon the properties of matter. Most of these are standard in college laboratories, although several are somewhat novel, notably the last two, for determining liquid viscosity. The third chapter, occupying over half of the first volume, gives the theory and directions for 25 experiments in optics. Of these, several are unusual in a college or engineering course, particularly those which employ the spectrograph, spectrophotometer, colorimeter and polarimeter.

Vol. II contains four chapters, the first including 4 experiments upon vibratory motion, the second 10 in sound, the third 20 in heat, the fourth 24 in electricity and magnetism. Among these experiments are several usually performed in courses more advanced than those in general physics as given in most colleges or engineering schools. The author, while he states that some of these would be performed only by students specializing in physics, evidently believes that these more difficult experiments rightfully belong among those performed by the student during the time occupied by him in laying foundation for later more technical scientific knowledge. With this in view, the writer of this review fully agrees.

On the whole this manual is on a considerably higher plane than most of its kind.

THE PRINCIPLES, OPERATION AND PRODUCTS OF THE BLAST-FURNACE. By *J. E. Johnson, Jr.* 552 pages, illus.; price $5.00. McGraw-Hill Book Co., Inc.

This is the companion volume to the same author's "Blast-Furnace Construction in America." Together the two volumes form the most comprehensive treatise in any language on the subject of the iron blast-furnace, upon which J. E. Johnson, Jr., by virtue of his education and long practical experience, was an established authority. In the first six chapters of the book are discussed the chemical, thermal and mechanical principles in a manner which has the rare combination of being both exhaustive and clear. Of the chemical principles, Sir Lowthian Bell will long be remembered as the original and greatest expounder, while Johnson was likewise recognized as the exponent of the now generally accepted thermal theory, involving a critical temperature and available heat in excess of that temperature—a theory which had to win its way to a position of authority against the conservatism of many a learned professor, especially of the German school.

More than one-half of the book is devoted to the application of these several principles under the head of "Operation," in which place are treated the ascending column of gases and descending column of solid materials, slag, burdening, rate of driving, handling the furnace, irregularities and their treatment, and the combustion of gas. One notices a weakness in the lack of specific directions as to the application of some of the principles; for example, in no place do we find instructions as to the difference in practice when making foundry pig iron, ferromanganese and ferrosilicon. Truly the general principles are laid down with force and clarity, so that any capable and intelligent man can apply them and obtain the answer for himself, but for students and those who prefer to have others do their thinking for them, the classified repetition would be welcome.

Under the head of "Products" the author gives a good, scientific, although brief, account of the various commercial forms of pig iron, the effect of different elements, and the principles governing these effects. It will be remembered that Johnson was the first to publish (*American Machinist*, April 5, 1900, page 317) the theory of steel and cast iron as a continuous series of alloys of iron and carbon. The argument and the information given to practical foundrymen in this book are good; the micrographs are excellent and bring out well the points they illustrate.

The book closes with a valuable, thoughtful section on "Commercial Considerations and the Future Possibilities." There is an index, which is too perfunctory in character and limited in scope.

EXPLAINING THE BRITISHERS. By *Frederic William Wile*. Price $0.85, 118 pages, illus. Published Autumn, 1918. London: William Heinemann.

One of the most important things accomplished by the war was the establishment of more intimate and friendly relations among individuals of the allied nations. The American, for example, discovered the Britisher, and found, possibly to his surprise and certainly to his pleasure, that the latter was quite as natural and interesting a human being as his descendants in America. The book under consideration was written by an American for the purpose of explaining to the members of the American Expeditionary Forces some of the little peculiarities of our British friends. It was also designed to give the American and any one else who will read it a clearer idea of Great Britain's contribution to the war, dispelling the crude notion that England was not playing the game to the limit. Although written before the armistice was declared and primarily to predispose American troops favorably toward their brothers in arms, the book will have a permanent value in creating the proper spirit among members of the English-speaking races. It is written in the agreeable style of a versatile newspaper writer and presents facts and figures in an easy manner. It can be read with pleasure by every good American and with profit by any one who has been inclined to give ear to anti-British propaganda.

THE APPLICATIONS OF ELECTROLYSIS IN CHEMICAL INDUSTRY. By *A. J. Hale*. ix + 148 pages, illus. Cloth. Price $2.50 net. New York: Longmans Green & Co., 1918.

This book is one of the Monographs on Industrial Chemistry edited by Sir Edward Thorpe. It consists of an introduction and eight chapters. The introduction gives an account of the general principles of electrolysis and an explanation of electrochemical terms. The chapters have the following headings: Methods of Generating the Current; The Electrolytic Refining of Metals; The Electrolytic Winning of Metals; Electrolytic Production of Hydrogen and Oxygen; Chlorine and Caustic Soda; Hypochlorites, Chlorates, Perchlorates; Production of Inorganic Compounds.

This work is principally a description of the important electrochemical industries, is very readable and is on the whole a good introduction to the subject. The paper and print are excellent and the book has a pleasing appearance.

As it is the unpleasant duty of the reviewer to point out inaccuracies or omissions, the following must be mentioned. In the introduction, the inaccurate statement is made that when copper sulphate is electrolyzed between copper plates there is no back e.m.f. of polarization. In the chapter on methods of generating current, it is stated that lead storage battery plates are generally formed by the old Planté method of alternate charging in opposite directions. On the same page, the reactions at the plates are represented as occurring in two steps, involving loss of free energy cor-

responding to the reaction $PhO + H_2SO_4 = PhSO_2 + H_2O$, which loss does not occur. In the refining of metals, the explanation of why anode impurities behave differently is not given, and in describing the series system, it does not explain how the pure copper is separated from the undissolved impure copper. Other similar points might be mentioned. In the chapter on the winning of metals, nothing is said of the important process for producing copper used at Chuquicamata, Chile, and of similar work in the United States. Finally, the Darling process is incorrectly stated to be regarded favorably in America, while it has never been a success.

TREATISE ON APPLIED ANALYTICAL CHEMISTRY. By *Prof. Vittorio Villavecchia*, Director of the Chemical Laboratories of the Italian Customs, translated by *Thomas H. Pope*, B. Sc., A. C. G. I., F. I. C., University of Birmingham. 1918. Vol. II. Price $6.00. 536 pages, 105 illus. Philadelphia: P. Blackiston's Son & Co.

The first volume of this work was reviewed in our Vol. xviii, p. 488. This, the second volume, contains a good treatise on analytical chemistry applied to foodstuffs such as meat, milk, flour and beverages, and to some additional industrial products such as essential oils, varnishes, inks, leather and coloring matters. In wine and spirits we shall have at least an academic interest hereafter, and we will find much information here. Essential oils are well treated. Rubber, which was noticed by the reviewer as being absent from the first volume, is fairly well discussed.

It is curious to observe how the author's tastes or experiences are indicated by the relative amount of text under each head. Milk and its products occupy 22 pages; flour and derived products, 30 pages; sugar, 77 pages; varnishes, 7 pages; inks, 5 pages; leather, 9 pages.

Among industrial or food substances which might have been treated but are not found in these volumes are glass, clays for ceramic and refractory materials, paper and cardboard, explosives. The discussion of textile fibers as well as fabrics, of tests of their waterproofing, quality of methods for determining the weighting of silk, degumming, etc., as well as identification tables for coloring matters, make a particularly thorough chapter. Each one of these reviews of analytical methods is closed by a critical digest of the subject with emphasis upon the best criteria to rely upon. This is a good feature.

The cuts on prepared paper are good; the remaining cuts in many cases crude in drawing and poorly printed.

GAS AND FLAME IN MODERN WARFARE. By *Major S. J. M. Auld*, Royal Berkshire Regiment. Price $1.35. New York: Geo. H. Doran Co.

Shortly after the United States entered the war there was a great commotion about gas, and yet nobody seemed to know much about it. At least, only a few persons did. Of the vast majority, some knew a little, and were as secret as comic opera conspirators about it; others knew more—that is, they knew parts of more, but not the whole of anything. There was, however, one person among the few who was abundantly informed, who had had large experience, and who had a clear notion of what might be told and what might not. He was a strenuous worker in getting production started, a man of amazing ubiquity, approachable, affable, and keen as a whistle. It is not surprising, therefore, that when inquiries were made about this new method of warfare, the usual answer was, "See Major Auld if you can; he knows all about it." It is not of record that he ever overstepped the mark, or gave out information that would be of value to the enemy.

The gentleman was Major, now Colonel, S. J. M. Auld, sent here by the British at the request of the U. S. Government to aid us in those preparations for gas warfare which finally helped to take the heart out of Fritz and to impress upon no less a person than the great Von Ludendorff himself that there was something wrong about that last German "victory" drive. Colonel Auld is a chemist of parts; he wears the Military Cross for crawling into enemy trenches to observe the effect of a British gas attack, and he has been wounded in battle. A good soldier, and, as we should say, a live wire. He was in the trenches opposite Messines in April, 1915, when the Germans launched their first gas attack, and he was in the thick of the business from that time until the end of the war. His book, "Gas and Flame," tells the story very much as one would expect him to talk to a favored group of men sitting about a cosy fire in a pleasant club. It was designed for the general public rather than technical men, nevertheless the facts as to gases and what they are, are duly set forth.

The onus of introducing gas to the German military authorities and persuading them to use it he lays at the door of Professors Nernst and Haber. Nernst was one of the most arrogant pan-Germans and Anglophobes, and was made a Count (Graf) by the Kaiser for his "distinguished services." Long before the war started Haber and his assistants were known to have been working on poisonous arsenical gases and liquids. Haber also directed operations in the field. The first respirators, the helmets, and the joys and sorrows of drilling men to use them, are all described with the art of a good réconteur. And a great deal of incidental information is given for valid reasons. Of course the direction and speed of the wind in cloud attacks were matters of first importance, and "Beaufort's Scale," as it is called, devised long ago by a British Admiral of that name, was occasionally called upon when instruments were lacking. It is worth remembering:

"If smoke moves straight up, the speed of the wind is nil; if smoke slants, the speed is two miles an hour; wind felt on the face indicates five miles an hour; if paper and the like move about, the speed is ten miles; when bushes are seen to sway, it is fifteen; if tree tops sway and wavelets are formed on the water, it is twenty; and if treetops sway and whistle, it is thirty miles an hour."

The book follows the course of the war until it was written—which was before the armistice was signed. The interest never flags, and good stories abound from start to finish. The last chapter on Flammenwerfer shows the limitations of this method of warfare. There isn't much chance for the man that directs the flame, and it is only in surprises at very close quarters that he can accomplish anything with it.

GENERAL LECTURES ON ELECTRICAL ENGINEERING. By *Charles Proteus Steinmetz*. Fifth edition, compiled and edited by J. L. Hayden, 242 pages, illustrated; price $2.50. New York: McGraw-Hill Book Co., Inc.

So many material changes have taken place during the eight years since the earlier editions of these lectures were published that the author has entirely rewritten large parts of the previous editions and has made material changes and additions to some of the other parts.

These eighteen lectures deal with the generation, transmission, control, distribution and utilization of electric energy. They are written in the lucid, logical, easily understood style, with no waste of words, for which this author is so well known and which always assures him a large attendance at his lectures in various cities. After listening to one of these, no matter on what subject, one always feels that he has learned something or has learned to look at problems in a new or more logical and rational way; the well known and brilliant work done by the author also gives one the assurance that what he says is so, and that his conclusions reached in controversial subjects are the results of a logical, impartial and highly intellectual treatment by one who is exceptionally well posted and has had a vast amount of practical experience.

In the present volume the treatment is of this kind; the lectures are written in easily understood style, essentially descriptive and not mathematical or highly technical. No space is wasted in long historical descriptions of the many things which have been abandoned and superseded; indeed, one of the most valuable features of these lectures is that he gives the conclusions which have been reached as to what is considered the best and the standard practice of to-day, as also the reasons which have led to these conclusions. Another valuable feature is the discussion of the relative advantages and disadvantages of different apparatus and methods, which determine the best choice under different conditions.

Unlike the custom in so many books the author does not begin with "Adam and Eve" but assumes a general familiarity with the subject of electrical engineering, but on the other hand the style is such that no expert knowledge of the subjects is necessary to understand his treatment of them; highly mathematical discussions are almost completely absent.

The subjects of this collection of lectures are: General review; general distribution; light and power distribution; load factor and cost of power; long distance transmission; higher harmonies of the generator wave; high frequency oscillations, surges and impulses; generation; hunting of synchronous machines; regulation and control; lightning protection; electric railway; electric railway motor characteristics; alternating-current railway motors; electrochemistry; the incandescent lamp; arc lighting; modern power generation and distribution. The numerous methods of distribution, with the economy of copper conductors and their other advantages and disadvantages, are very clearly explained with simple diagrams. In discussing the cost of power, he adds to the usual two factors of fixed cost and a cost proportional to the power a third one, depending on the reliability of service required, which embraces the reserve. The discussion of the generation of the power, by water, steam engine, steam turbine and gas engine, is logical and instructive. Quite a long lecture is on the alternating-current railway motor. The lecture on electrochemistry is quite brief, dealing only with a few fundamentals, and from the practical standpoint. In the eighteenth lecture he expresses the opinion that at least for a long time to come there is very little probability that any form of internal combustion engine will even approach the efficiency of the steam turbine, which he considers has become and will remain for some time the "next feature"—the universal source of primary power.

His statement that "electricity is the most useless form of energy . . . and finds no industrial use as electrical energy" is one of those statements that startle one at first, until he explains that to be useful it is always converted into some other form of energy, such as light, mechanical energy, chemical energy, heat, etc., it being the connecting link between the original energy and its final useful form. He shows that with regard to energy, electrical transmission becomes what the railway system is with regard to the transmission of materials.

The volume concludes with an abstract of a recent lecture before the Franklin Institute, and a table giving the reactances for overhead lines.

THE FLOTATION PROCESS. By *Herbert A. Megraw*, 6 x 9, 359 pages, illustrated. Second edition, revised and enlarged. New York: McGraw-Hill Book Co.

The second edition of Megraw's book is a commentary upon flotation in more ways than one. It is both a good book and a poor book at the same time, for even after much excellent reading matter has been added it yet remains mainly a compilation. While Mr. Megraw has written an excellent introduction to the study of flotation for use of a technical student or an operator just taking up this process, the second edition will be found as disappointing as the first by the man who has been doing the actual work and has made it a rule to follow flotation literature as it has appeared.

Unfortunately, investigators, superintendents and managers generally can find little time, official encouragement or energy to write upon the subject they understand so well. It seems therefore inevitable that our technical books shall be written by students of an art rather than real practitioners. Even this state of affairs has certain compensation, since the author can generally draw upon the personal experiences and observations of the leaders in that art freely. Thus it is that our modern technical books show such general excellence.

In the main, Mr. Megraw has had to labor without such aid. He has visited many mills, and read extensively upon his subject. His condensations of his readings are excellent, and he has compiled with judgment. He is therefore not to blame for the shortcomings of his book. He had a right to expect that by this time flotation under the virile leadership of American engineers would have thrown off the yoke of Minerals Separation. In certain clauses of its licenses Minerals Separation strictly forbade all publication or dissemination of knowledge in regard to the art of those using its process, and in addition it claimed ownership of any new discoveries in the general art of flotation made while using its process. For years it succeeded in preventing the publication of many articles dealing with froth-flotation in Australia and in England, and as a result the process never advanced as it should until it was introduced into the United States. Here engineers, metallurgists and editors have largely refused to submit to such dictation, and as a result there has been more real advancement in the last four years than ever before. This advancement has been not because of Minerals Separation but in spite of Minerals Separation. Among editors Mr. T. A. Rickard deserves especial praise for the fearless way in which he has exposed all attempts to prevent the dissemination of technical knowledge even upon flotation. Among mining companies the industry owes gratitude to both Miami and Butte & Superior for the costly fight which they have made against the monopoly.

While other patentees have perverted our patent-law system to their advantage by various clauses in their licenses regarding use, sale and prices, the reviewer believes none has heretofore had the effrontery to try to use rights acquired under an "Act to Promote the Progress of the Useful Arts" to the direct, malicious purpose of preventing the spread of knowledge in that art.

Until that time when flotation has thrown off this clutch we must expect all books upon flotation to be mainly compilations of the writing of those fearless practitioners who righteously tell Minerals Separation to go to, and in public spirit give to the industry the benefit of their observations. Mr. Megraw therefore is to be praised for his public-spirited preparation of a second edition of his book.

Personal

PROF. COMFORT A. ADAMS, who is president of the American Institute of Electrical Engineers and was recently elected president of the American Welding Society, has been chosen dean of the faculty of the Harvard School of Engineering at Cambridge, Mass.

PROF. ALAN M. BATEMAN, of the Department of Economic Geology, Yale University, New Haven, Conn., has become editor of the *Journal of Economic Geology*.

MR. GEORGE G. BROWN, formerly chemical engineer with the Aluminum Co. of America, Messena, N. Y., and chemist for the development section, research division, Chemical Warfare Service, at the American University, Washington, D. C., is now chief engineer for the Universal Aniline Dyes & Chemical Co., Milwakee, Wis.

MR. E. C. CHERRINGTON and MR. T. R. COOLEY have been transferred from the Milwaukee office of the Cutler-Hammer Mfg. Co. to the Pittsburgh office in the capacity of office manager and engineering correspondent, respectively.

DR. FREDERIC DANNERTH has accepted an invitation from the Newark Technical School to deliver a course of thirty lectures on corporation chemistry.

MR. J. F. DEAN, formerly chemical engineer for the Southwestern Portland Cement Co., has resigned to become consulting chemical engineer for the Canada Cement Co. of Montreal. Mr. Dean has been especially active on matters connected with potash recovery.

LIEUTENANT-COMMANDER H. J. ELSON, U. S. Naval Reserve, has been released to inactive status and has resumed his position as secretary and treasurer of the Walter A. Zelnicker Supply Co., St. Louis, Mo.

CAPTAIN GEORGE H. HALL, Ordnance Department, Watertown Arsenal, has been discharged and resumed his position as manager of ozonator sales for the Sprague Electric Works of New York.

Mr. Arthur Lachman has resigned his position as vice-president and general manager of the Great Western Electro-Chemical Co. and the California Alkali Co. These connections were established in the interest of war production in needed chemicals but, that necessity no longer existing, Mr. Lachman will devote himself to his own interest with offices in the Holbrook Building, San Francisco.

Mr. John A. MacKenzie, consulting and designing engineer, formerly with E. B. Badger & Sons Co., is now connected with the Oakland Copper & Brass Works, Seventh and Kirkman Streets, Oakland, Calif.

Dr. Paul D. Merica, formerly of the metallurgical division of the Bureau of Standards, Washington, D. C., is now physical metallurgist in the research department of the International Nickel Co., Bayonne, N. J.

Mr. Philip N. Moore, past president of the American Institute of Mining and Metallurgical Engineers, has been appointed by the Secretary of the Interior to serve on the commission to adjust claims growing out of governmental efforts to stimulate production of war minerals. Mr. J. F. Shafroth and Mr. M. D. Foster are also on this committee.

Captain G. A. Roush has been discharged as chief of tests, metallurgical branch, inspection division, Ordnance Department, and has returned to his former position as assistant professor of metallurgy, Lehigh University, South Bethlehem, Pa.

Mr. F. V. Sargent has been appointed by the Chicago Pneumatic Tool Co. district manager of sales in the Boston territory, with headquarters at 182 High St., Boston, Mass.

Mr. A. J. Seltzer, former chemist for the Bartlesville Zinc Co., Blackwell, Okla., has opened an assay office in Picher, Oklahoma.

Mr. H. D. Trounce has accepted a position with the explosives division of the Bureau of Mines, with headquarters in Washington, D. C. His address will be Room 1128, the New Interior Building.

Mr. A. P. Watt was married on April 2 to Miss Ethel May Morse of Brooklyn, N. Y.

Obituary

Mr. H. R. Hancock, inventor of the jig and rock-drill that bear his name, died on Jan. 15 at the age of 83. Mr. Hancock was for twenty-two years in charge of the Wallaroo and Moonta copper mines in South Australia, which will now be managed by his eldest son, H. Lipson Hancock.

Mr. Alexander Cochrane, formerly president of the Cochrane Chemical Co. of Everett, Mass., died suddenly at his home at the age of 79. Mr. Cochrane was one of the original directors of the American Bell Telephone Co. and was identified with the development of its service.

Mr. Edward F. Freudenthal, mine operator and promoter of Pioche, Nev., died on March 24 at the age of 55 years. He was a native of Pioche and had always made his home there, although spending much time in Salt Lake City and in the East. He is survived by his widow, two sons and a brother.

Sir William Crookes, chemist and physicist, died in London April 4, 1919, at the age of 86. He was born in London June 17, 1832, and entered the Royal College of Chemistry at the age of 16. In 1851 he was assistant professor at the same institution. In 1859 he founded the *Chemical News* while in charge of chemical instruction at Science College, Chester. As editor of the *Chemical News* for sixty years Sir William enjoyed the distinction which has come to few if any editors of scientific papers. The discovery of thallium is credited to Sir William, resulting from an examination of the residue left in the manufacture of sulphuric acid. Crookes tubes and their familiar phenomena, known to every student of physics, were also his invention. Sir William was a publisher of many papers and books, among them being "Select Methods in Chemical Analysis," "Manufacture of Beet Root Sugar in England," "Handbook of Dyeing and Calico Printing" and translations of treatises on metallurgical and chemical technology. Sir William was knighted in 1904 and was the recipient of many honors from scientific societies in Europe. He was married in 1856 to Ellen, daughter of W. Humphrey. His wife died in 1916.

Mr. Harry E. Hollister died in Newark, N. J., on March 29. He was born in Newark on Nov. 29, 1887, and was graduated from the Newark Technical School in June, 1907. At the outbreak of the war he offered his services and was assigned to important duties in the development and construction of the large government powder plant at Nitro, W. Va. An article describing his work in this connection appears in this issue of this magazine. For several years he practiced his profession of chemical engineer, designing and building numerous chemical plants and developing several patented chemical apparatus and processes. Upon the cessation of hostilities he became associated with the Leonard Construction Co., New York, and was stricken while developing, on a commercial basis, one of his most valuable processes. At one time he was connected with Lockwood-Greene & Co., Boston, Mass., industrial engineers, and resigned to accept a position as assistant engineer with Harrison Bros. Co., Philadelphia, paint and chemical manufacturers, where he had charge of the design and construction of extensive chemical and paint manufacturing improvements. Later he was appointed chief engineer of the Kalbperry Corporation, New York, chemical engineers, and the Franklin H. Kalbfleisch Co., New York, chemical manufacturers.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, April 12.—Prices on the non-ferrous metal market have not materially changed since our last report and demand has slackened to some extent.

Aluminium:—Conditions are unusually quiet, as aluminium has not declined. Ingots 98-99 per cent, 31c. lb. Sheets, 18 gage and heavier, 42c. Powder, 0.70-1.40 lb.

Antimony:—Wholesale lots are offered from 6¾ @ 7c. and jobbing at 7¼c. There was a slight improvement in buying.

Copper:—Moderate activity with slightly improved prices over our last report. The closing price was 15¼ @ 15⅝c. per lb.

Copper sheets, hot-rolled	lb.	$0.22½ — ....
Copper sheets, cold rolled	lb.	.23½ — ...
Copper bottoms	lb.	.30½ — ..
Copper rods	lb.	.19½ — ...
Copper wire	lb.	.17½ — $0.18
High brass wire and sheets	lb.	.18½ — .....
High brass rods	lb.	.17½ — .....
Low brass wire and sheets	lb.	.18½ — .....
Low brass rods	lb.	.21½ — ...
Brazed brass tubing	lb.	.29½ — ....
Brazed bronze tubing	lb.	.33½ — ....
Seamless copper tubing	lb.	.28 — ....
Seamless bronze tubing	lb.	.29½ — ....
Seamless brass tubing	lb.	.30 — ....
Bronze (gold) powder	lb.	1.00 — ....

Lead:—Prices have declined to 4.75c. per lb. in East St. Louis and 4.975c. per lb. in New York. Sheet lead, 7¾ @ 8c. per lb.

Tin:—The fixed price of 72½c. will remain until the 10,000-ton allotment is liquidated, which will be from sixty to ninety days yet.

Zinc:—Spelter has slightly improved in price and the East St. Louis price closed at $125 per ton. Zinc dust 14c.; sheet zinc, 11c. per lb.

OTHER METALS

Bismuth	lb.	$3.20 —$3.65
Cadmium	lb.	1.40 — ....
Cobalt	lb.	2.50 — 3.50
Magnesium	lb.	1.75 — 2.10
Mercury	75 lb.	67.00 — 70.00
Nickel	lb.	.40 — .45
Tungsten	lb.	Nominal
Iridium	oz.	175.00 — ....
Palladium	oz.	115.00 —120.00
Platinum	oz.	99.00 —100.00
Silver	oz.	1.01⅛ — ....

The Iron and Steel Market

The situation arising from the refusal of the Railroad Administration to place orders based upon the reduced prices recommended by the Industrial Board and effective

March 21 has been very generally misrepresented. It has been made to appear that the director general was refusing to do team work that he ought to do, for the general good, and his stand for the conservation of the public funds has not been placed to his credit. While the steel producers desire to obtain as high prices as possible for their products, some of them frankly commend the director general for his attitude, recognizing that he was endeavoring to do his duty.

As to the conflict between the statements of costs submitted by the steel producers to the Industrial Board and the attitude of the Railroad Administration that it can buy steel at lower prices if left to itself, this is all a question of overhead. There was a statement made, for instance, that the cost of producing bessemer rails in January was $46, but production was very light and necessarily a large overhead was charged.

There was undoubtedly a great difference of opinion between the steel producers and the Redfield board as to the demand that could be expected for steel. In vouchsafing but moderate reductions in steel prices, the reductions of March 21, together with those of last December, making an average of $11 a net ton from the Government schedule, not considering rails, the steel producers probably expected relatively light operations for several months. The Redfield board expected, undoubtedly, a fairly large demand for steel. If there were a large demand, the overhead would be so distributed that considerably lower prices could be accepted and still leave large profits, and the profits for 1919 will be taxed much less heavily than were those of 1918.

Sentimental Influences

It has been made to appear in many quarters that railroad buying would of itself produce much more activity in the steel trade. That is not true. The heaviest railroad buying that could possibly be expected, considering the uncertain position of the railroads, their light traffic and their earnings at very much below the Government guarantee, would amount to very little, in point of tonnage, to the steel trade. The hope was that if the Railroad Administration should buy with apparent freedom the public would then be moved also to buy, and its buying would furnish the really important tonnage. The public, however, had already given an inkling of its attitude as to the price reductions of March 21. Immediately after the reductions were announced there was a mild spurt in orders, but clearly this represented simply the orders that had been held back in anticipation. Now, when the total of bookings for the month of March can be scrutinized by the steel producers, they find that the spurt in buying did not make up for the previous lull, as compared with the buying rate in January.

It was expected that if the Railroad Administration endorsed the steel price reductions offered it would first buy rails, since rails are needed for upkeep. Cars and locomotives might follow, but it is not certain additional cars and locomotives will be needed in the near future. Improvements, by way of bridges, buildings, new lines, etc., would be farther in the future, and the undertaking of a comprehensive program would be of doubtful expediency when the disposition of the railroads has not been settled, or the conditions under which they will operate if, as seems altogether probable, they will be returned to their owners.

As to rail orders furnishing a stimulus to the steel industry, however, there were two unfortunate circumstances. Using open-hearth rails for illustration, bessemer rails being uniformly $2 less, the railroads had bought rails only at the $30 price which ruled up to May 1, 1916, then at $35, and then at the $40 price which became effective late in 1916. These were base prices, there being premiums for particularly stringent specifications. Last September the War Industries Board had approved a $57 price for open-hearth rails, which price obtained in various settlements for rails bought to prosecute the war, but the Railroad Administration never accepted the price. When, therefore, the Redfield board "reduced" rails from $57 to $47, it was asking the railroads to pay an advance. It is understood there is still due the railroads about 500,000 tons of rails at the basis price of $40 or less, on which shipments have been going out at the rate of 40,000 tons a week, which would carry the roads, in general, to July 1. It has not been shown that the railroads desire to lay rails at the rate of more than 40,000 tons a week. Thus in this matter of business being stimulated by the Railroad Administration buying rails there were two awkward circumstances—that what amounted to an advance in price was being asked, and that there was a fair supply of rails.

When the steel industry's capacity is fully 36,000,000 gross tons of finished steel products a year, the buying of a few hundred thousand tons more or less of rails cannot have much direct effect. The sentimental effect would be very considerable, perhaps, but that has not been proved. When the subject was so thoroughly aired it became certain that even should arrangements eventually be perfected whereby the Railroad Administration would buy, the sentimental effect would be lost. Accordingly sentiment has been growing in the steel trade that an open market is the only recourse, prices being allowed to go where they will. There is a disposition also toward a changed view in the matter of wages. With light operations the earnings of the men are very considerably reduced, and wage reductions might be effected without much complaint arising. Reasons that are largely sentimental in character are responsible both for the strenuous desire of Washington officials that wages be not reduced and for the equally strenuous desire of many steel producers that they be reduced. The latter would like to see reductions in order to preserve appearances, on account of repeated claims that steel prices could not be reduced unless wages were reduced.

The view that there should be an open market in steel is very far from universal, but it is growing more common. It is, perhaps, the optimistic view rather than the pessimistic. It looks to the possibility that an important volume of demand can thus be brought out. The other view is that demand cannot be materially stimulated and that prices should therefore be maintained, because of the high overhead per ton when operations are light.

Among the merchant furnaces the view has become quite general that there should be an open market, but pig iron is different from steel. The blast-furnaces have always had more or less competition between districts, and the recommended price schedule, which is simply $7.25 reduction from the Government schedule, with its complicated basings, entirely out of line with the alignments maintained by competition before Government price control began, must necessarily be unsatisfactory to one district if it proves satisfactory to another. The merchant furnaces feel that the way to reduce costs is to blow out, and many are doing so. Really competitive bidding cannot come, of course, until there is at least a moderate volume of inquiry, and thus far there has been practically none.

Production

Steel ingot production in 1918 is now reported by the American Iron and Steel Institute at about 43,027,000 gross tons, against 43,619,200 tons in 1917 and 41,401,917 tons in 1916. Since the middle of 1917 monthly reports of ingot production have been made by 29 companies. In 1916 these companies had made 88.14 per cent of the total output. In 1917 they made 85.1 per cent of the total, and completion of the 1918 total now shows that they made only 83.5 per cent of that year's output. This explains why the 1918 production proves to be slightly larger than had been indicated by previous estimates, based on the showing of the 29 companies. The estimates of rates of production in January and February of this year must also be revised. Reports are now made by 30 companies, which made 84.03 per cent of the 1918 total. On the basis of this 84.03 per cent, and counting the number of steel working days in the months and year, the country's rate of steel ingot production has been as follows: January, 42,600,000 tons, or 86.9 per cent of capacity, taken at 49,000,000 tons a year; February, 41,700,000 tons, or 85.1 per cent; March, 37,900,000 tons, or 77.3 per cent.

Even the March rate, although 11 per cent under the January rate, seems high in view of the generally reported stagnation in trade. The explanation offered by mills is that they are running chiefly on old orders, and they do not seem to expect new orders to take the place of old orders as they are worked out.

The Chemical Market

COAL-TAR PRODUCTS. — Producers generally report a marked increase in the volume of business for coal-tar products, although buyers are seemingly not disposed to bring their full demands in the market and seem to be confining their purchasing to immediate needs, but even this condition is having no effect in the steady increase in business. Consumers are becoming more reconciled to the market conditions, in view of the recent decline in prices, which appear to be more in accordance with their ideas. Producers are looking forward to an early resumption of activities and state they are well satisfied with the developments, apparently brought about, in part, by the settlement of the textile labor troubles, and this trade seems to be gradually becoming more active in purchasing dyes, which reflects materially on the crude and intermediate situation.

Phenol:—Considerable stock is reported to be changing hands, but second hands who were holding large quantities seem to be well sold up and the market has firmed up very noticeably.

Benzol: — Comparatively large quantities are reported being sold and second hands seem to have little if any material to offer, which tends to keep the market steady, and manufacturers are firmly maintaining prices.

Toluol: — Producers report a satisfactory business passing, but individual sales generally represent small lot transactions. Prices are quotably unchanged and the market is on a firmer basis.

Benzoate of Soda: — Resale offerings are still liberally made and in consequence lower prices have been brought about. The acid continues to be considerably neglected and keener competition among second hands has brought about some radical reductions in prices.

Alpha Naphthylamine:—Prices are firmly maintained by producers, despite the quietness generally prevailing.

Benzidine:—No important changes. The market is fairly active and steady at the recent decline in prices. There is a fair demand for the base product for export purposes, while local requirements are of moderate proportions and no particular interest is noted for the sulphate variety.

Beta Naphthol: — A fairly active trading is evident for the various grades, but available material is more than sufficient for the current call. However, no price changes have been effected, with a rather steady market prevailing.

Beta Naphthylamine:—Quotations for both the technical and refined products are held steady by producers, who report a fair volume of business passing, but the demand is by no means pressing.

Diethylaniline:—Large quantities are available at present, with new producers having recently entered the market. While the demand is slightly better, there are sufficient stocks for additional business and prices are lower.

Dimethylaniline:—There is not a great deal of business passing, despite the fact that offerings are made at some rather low levels and small lot trading continues to feature the market.

Naphthalene: — Buyers are displaying no unusual interest, but a fairly steady movement is reported at present, for the ball material, the activity being created by the drug trade, but trading even in this direction seems to be somewhat restricted. Some cheap offerings occasionally appear in the resale market, but trading for the most part is direct and manufacturers are making no price concessions to stimulate additional business.

Orthonitrophenol:—Trading is confined to small lots and stocks seem to have accumulated to a very noticeable extent, with offerings among second hands being made at 3c. to 5c. below manufacturers' prices.

Paranitrophenol:—While consumption requirements are of no unusual proportions, offerings are none too liberally made, but available supplies seem to be more than sufficient for the current call and the sales noted are closed at some low levels.

Paranitraniline: — Quantities of this material have now appeared on the market and keener competition among second hands has brought about some cheap offerings. Manufacturers are striving to keep the market steady and have not altered their prices since the recent decline.

HEAVY CHEMICALS.—Trading in the general market reflected a little more confidence in the ultimate betterment of conditions, although stocks in most instances are more than sufficient for the call. The bulk of the business is in limited quantities, but repeat orders are more frequent. Second hands are still, for the most part, the only factors actually doing anything in the way of active business, while manufacturers are seemingly not disposed to meet the resale market prices, but state a satisfactory business is developing and see no necessity for making any effort to meet this situation. Caustic soda and soda ash, the barometers of the heavy chemicals, seem to have been subject to a better call, particularly caustic soda, for which some important sales have been consummated for export purposes, and prices have been firmly maintained. On the other hand, no unusually large transactions were reported for soda ash, although trading has been of sufficient volume to take the slack off the market.

Soda Ash: — The consuming trade seems to be steadily taking a fair portion of supplies, but buyers are apparently not interested in any forward stocks and there seems to be sufficient spot material to meet the current call. Bag material from the warehouse was sold at $1.50 per 100 lb., with offerings made at this figure in some directions, but other quotations range up to $1.55 and $1.60. Double bags in the Middle West were nominally quoted at $2.15, while barrels ex store were as low as $1.60, with other directions holding at from $1.70 to $1.75.

Caustic Soda: — While the demand is not of a pressing nature there seems to be more interest on the part of buyers, and sales of 100 and 200 tons seem to have been more frequent at prices ranging from $2.75 to $2.80 f.a.s. per 100 lb. Second hands, who seem to control the market for the most part, were offering ex-warehouse material at from $2.65 to $2.70 and were offering on a basis of $2.75 to $2.80 f.a.s. Ground caustic continues to be neglected, with material available at 3½c. per pound.

Bleaching Powder: — There has been no increase in the interest for this commodity, particularly for local consumption, where buying seems to be conducted on a hand-to-mouth basis, while export trading seems to be somewhat more active. Large domestic drums were offered in the resale market at $1.60 ex-dock, and first hands are quoting this figure, at the works. Export drums were offered by second hands at 2¼c. f.a.s., with manufacturers holding at 2½c.

Bicarbonate of Soda:—The continued absence of any important demand has had its effect in the market and some resale lots were reported sold as low as $2.25. This, however, is not regarded as representative of the market, as material in barrels, in most directions, was held at $2.50 per 100 lb., while that in kegs was offered at from $2.65 to $2.70.

Bichromate of Soda:—Very little business. In fact, the market is so dull that reports are still heard of further reductions in prices. For instance, there were offerings of spot material as low as 10c. for some of the standard brands, while others were quoting 10¼c. to 10½c.

Caustic Potash: — Recent price reductions seem to have had some effect in stimulating business, although the present rate of absorbing stocks is having no effect, as the production of the material is reported to be quite heavy. Some grades of the 88-92 product are offered as low as 40c., with others still holding at 48c.

Cyanide of Soda: — There has been little in the way of active trading; however, the production of the commodity is confined to a few quarters, therefore prices are firmly maintained at from 30c. to 31c., according to quantity.

Copper Sulphate: — Little in the way of any important sales are noted and small lot transactions continue to feature the market. The production is probably heavier than for some time past and prices are easier at 7c. for outside brands, with other grades of the large crystals 99% being quoted at 7¼c.

Chlorate of Soda: — The continued absence of any important demand has had its effect of a weakening market, with price reductions noted in most directions. Sales were reported as low as 15c., although 17c. to 18c. seems to be the general market quotation.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET APRIL 8, 1919

Acetic anhydride	lb.	.65 —	.70
Actone	lb.	.15½ —	.16
Acid, acetic, 28 per cent	cwt.	3.25 —	3.40

Coal Tar Products (Crude)

NOTE—The following prices are for original packages in large quantities:

Anthracene, 80% in drums (100 lb.)	lb.	$0.90 —	$1.00
Benzol, pure, water-white, in drums (100 lb.)	gal.	.22 —	.27
Benzol, 90%, in drums (100 lb.)	gal.	.22 —	.27
Cresol, U. S. P., in drums (100 lb.)	lb.	.18 —	.....
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	1.02 —	.....
Cresylic acid, 95-97%, dark, in drums	gal.	.92 —	.....
Cresylic acid, 50%, first quality, drums	gal.	.60 —	.....
Dip oil, 25% tar acids, crudes, in drums	gal.	.38 —	.....
Phenol, U. S. P. drums (dest.), (240 lb.)	lb.	Nominal	
Pyridin	gal.	$2.50 —	.....
Naphthalene, crushed in bbls. (250 lb.)	lb.	.08½ —	.....
Solvent naphtha, water white, in drums, 100 gal.	gal.	.20 —	.25
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.18 —	.20
Toluol, in tank cars	gal.	.22 —	.....
Toluol, in drums	gal.	.23 —	.30
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal	gal.	.32 —	.40
Xylol, commercial, in tank cars	gal.	.30 —	.....

Intermediates, Etc.

Alpha naphthol, crude	lb.	1.00 —	1.10
Alpha naphthol, refined	lb.	1.20 —	1.25
Alpha naphthylamine	lb.	.45 —	.50
Aniline oil, drums extra	lb.	.24 —	.25
Aniline salts	lb.	.32 —	.34
Anthracene, 80 per cent	lb.	.50 —	.55
Benzaldehyde (f.f.c.)	lb.	1.30 —	1.50
Benzidine, base	lb.	1.00 —	1.15
Benzidine, sulphate	lb.	.95 —	1.00
Benzoic acid, U. S. P.	lb.	1.15 —	1.20
Benzoate of soda, U. S. P.	lb.	1.10 —	...
Benzyl chloride	lb.	.50 —	...
Beta naphthol benzoate	lb.	5.50 —	6.00
Beta naphthol, sublimed	lb.	.65 —	.....
Beta naphthylamine, sublimed	lb.	2.50 —	2.55
Dichlorbenzol	lb.	.15 —	.20
Diethylaniline	lb.	2.25 —	2.75
Dinitrobenzol	lb.	.30 —	.35
Dinitrochlorbenzol	lb.	.30 —	.35
Dinitronaphtaline	lb.	.45 —	.55
Dinitrotoluol	lb.	.40 —	.50
Dinitrophenol	lb.	.32 —	.34
Dimethylaniline	lb.	.55 —	.60
Diphenylamine	lb.	.70 —	.75
H-acid	lb.	2.10 —	2.15
Metaphenylenediamine	lb.	1.55 —	1.75
Monochlorbenzol	lb.	.12 —	.14
Naphthalene, flake	lb.	.07 —	.08
Naphthalene, balls	lb.	.10½ —	.11½

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

BISBEE—The Phelps-Dodge Corp. plans to resume work on concentrator.

CLIFTON—The city voted $150,000 bonds for the construction of sanitary sewers and treating plant. A. J. Kerr, town engineer.

GLOBE—The Iron Cap Mines Co. is having plans prepared by D. Cole for a mill.

JEROME—The United Verde Extension Mining Co., 233 Broadway, New York City, N. Y., plans to build extensions and additions to its copper smelter, here. G. Kingdon, general manager.

PRESCOTT — The Arizona Binghamton Mining Co. is having plans prepared by D. Cole for the construction of a mill and tramway. Estimated cost, several hundred thousand dollars.

Arkansas

ASHDOWN—The United Oil Mills plans to build a 2-story, 130 x 160-ft. oil mill and will require equipment for same. W. Foster, president.

LITTLE ROCK—The Dixie Cotton Oil Co., east of North Little Rock, will install a 12-press mill, in connection with the 2-story, 60 x 240-ft. oil mill which it plans to build. Total estimated cost, $250,000. W. F. Birdville, general manager.

California

LOS ANGELES—The Hollywood Studios, Inc., 6980 Hollywood Blvd., has awarded the contract for the construction of a motion picture plant, on Santa Monica Blvd., to the Milwaukee Building Co., Wright & Callender Bldg.; plans include the installation of film developing rooms. Total estimated cost, $250,000.

Connecticut

HARTFORD—The Board of Water Commissioners has awarded the contract for building a slow sand filtration plant, to the Foundation Co., 233 Broadway, New York City. Estimated cost, $627,508.

HARTFORD — The Hartford Rubber Works, 691 Park Ave., plans to build a 1-story, 60 x 80-ft. addition to its rubber factory on Booth Ave. Estimated cost, $18,000.

Idaho

QUARTZBURG—The Gold Hill & Iowa Mines Co. plans to build a mine plant, to include a mill, concentrators, cyanide plant, etc, and is in the market for cyanide machinery. Estimated cost, $300,000. E. E. Carter, superintendent.

Illinois

CHICAGO—E. H. Frommann, architect, 64 West Randolph St., is receiving bids for the construction of a 2-story, 125 x 200-ft. factory on Cortland and Kilbourne Sts., for the National Enameling & Stamping Co., 346 West Kinzie St. Estimated cost, $85,000.

ROCK ISLAND — C. W. Scott, 1338 2nd Ave., Davenport, Ia., has awarded the contract for the construction of a 1-story, 40 x 150-ft. factory for galvanizing to K. H. Cox, 905 Kirkwood Blvd., Davenport, Ia. Estimated cost, $3500.

Kansas

TREECE—The Big Elk Mining Co. plans to move Dorris mill from Quapaw and erect same at Treece, and is in the market for gas engine, rolls, rock drills and tables. C. Kelly, superintendent.

WESTVILLE—The Lucky Jew Mining Co., Commerce, Okla., plans to build a concentrating plant here. E. Depree, superintendent.

Kentucky

LOUISVILLE—The C. C. Stoll Oil Co., Shelby and River Sts., plans to build a refinery.

Louisiana

NEW ORLEANS — The New Orleans Petroleum Co., Woolworth Bldg., New York City, will build an oil refinery 15 miles from here. Estimated cost, $1,500,000. Work will be done by day labor.

Maryland

BALTIMORE — The Baltimore Copper Smelting & Rolling Co., 4th and 5th Aves., plans to build an addition to its plant.

HANCOCK—The Maryland Glass Sand Co., Hagerstown, plans to build a mill near here. Estimated cost, $50,000. R. J. Funkhouser, president.

Massachusetts

ASHLAND—The United States Color & Chemical Co., 15 Custom House, Boston, has awarded the contract for the construction of a 2-story, 50 x 84-ft. research building here, to the Pennsylvania Tile & Construction Co., 45 Milk St., Boston. Estimated cost, $50,000. Noted Feb. 15.

Michigan

DETROIT — The Central Forge Co., Euclid Ave., has awarded the contract for the construction of a 2-story, 70 x 302-ft. heat-treating plant and a 2-story, 70 x 302-ft. forge shop, on Euclid Ave. and Grand Trunk Railway tracks, to the Whitehead & Kales Iron Works, Beecher Ave. and Michigan Central R. R.

Missouri

ST. JOSEPH—The Conser Laundry Co., 908 Francis St., is in the market for one water softening plant, oil burners and a 12,000-gal. oil tank, etc. H. S. Lewis, chief engineer.

ST. LOUIS — The Mineral Refining & Chemical Co., Iron Mountain tracks and Des Pere River, plans to build an addition to its paint and pigment plant. Mineral milling equipment will be installed in same. Total estimated cost, $500,000. A. E. F. Versen, c/o owner, engineer.

ST. LOUIS—G. W. Niedringhause, 3745 Lindell St., vice president of the National Enameling Stamping Co.; C. Studebaker of the Studebaker Corp., 4300 Forest Park Bldg., and others plan to build a coke pig iron plant at Granite City. Estimated cost, $7,000,000.

ST. LOUIS—The Yawitz Dyeing & Cleaning Co., Suburban and Whittier Sts., will install a chemical laboratory in the 1- and 2-story, 50 x 135-ft. dyeing and cleaning factory, which it plans to build on Delmar and Walton Sts. Estimated cost, $50,000. S. Yawitz, president.

WACO—The Freehold Oil & Gas Co. plans to build a mill at its No. 3 shaft. W. S. Marquiss, manager.

WACO—C. Windbigler, Joplin, plans to move Old Jasper County mill from Prosperity and erect same at Waco, and is in the market for pumps, rock drills, belting and hoist. Estimated cost, $50,000. C. Windbigler, manager.

WEBB CITY—The Carlat Mining Co. plans to remodel and enlarge its plant, and is in the market for boilers, gas engine, rolls and belting. C. Cornett, manager.

Montana

BUTTE—The Boston & Montana Development Co., Daly Bank Bldg., plans to build a concentrator, and is in the market for complete concentrating equipment, coarse and fine crushing tables, etc. Estimated cost, $150,000. J. D. Pope, superintendent.

New Jersey

MILLVILLE—The Eastern Potash Co., 120 Broadway, New York City, plans to build a factory on the banks of the Raritan River here. Estimated cost, $2,000,000.

NEWARK—The General Leather Co., 420 Frelinghuysen Ave., has awarded the contract for the construction of a 2-story, 38 x 64 ft. drying building, to E. M. Waldron, Inc., 665 Broad St. Estimated cost, $14,000.

NEWARK—Nickelsburg Bros. Co., Meadow St. and Lincoln Highway, is having plans prepared by O'Rourke & Briscoe, architects, 45 Clinton St., for the construction of a 3-story, 50 x 100-ft. plant. Estimated cost, $30,000. Miller & Moran Chemical Works, lessees.

NEWARK—The Radel Leather Manufacturing Co., Wilson Ave., has awarded the contract for the construction of a 1-story, 40 x 110-ft. factory on Wilson Ave. and Central R. R. tracks, to the Reynolds Construction Co., 308 South 9th St. Estimated cost, $5000.

NEWARK—The Weldon Roberts Rubber Co., 117 Mechanics St., has awarded the contract for altering the 3-story, 86 x 112-ft. factory at 18 Oliver St., to Oschwald & Schmidt, 845 Broad St. Estimated cost, $10,000.

PHILLIPSBURG—The City Commissioners have approved $150,000 bond issue for the construction of a new sewer and sewage oxidation plant. C. E. Tilton, city engineer.

PHILLIPSBURG—The City Commissioners voted $65,000 bond issue for the construction of a sewage disposal plant and sewer lines. C. E. Tilton, city engineer.

New York

BROOKLYN—The Brooklyn Maternity Hospital, 670 Bushwick Ave., will install a chemical laboratory in the 4-story, 75 x 100-ft. hospital which it plans to build on Bushwick Ave. and Adams St. Total estimated cost, $70,000. M. Duckman, treasurer. Carlson & Wiseman, 226 Henry St., architect.

BUFFALO—The Mentholatum Co., 146 Seneca St., will soon award the contract for the construction of a 5-story, 100 x 160-ft. factory on the corner of Niagara and Brace Sts. Estimated cost, from $150,000 to $200,000.

CORTLAND—J. B. Webster, 3 Main St., and others have purchased the Redway Garage on Groton Ave., and will install an acetylene plant, metal working machinery, drill press, planer, miller, etc.

FREDONIA—The Bone Dry Lime Co. plans to build a plant for the manufacture of agricultural lime from the Cassadaga Lake marl, near here. Lime burning equipment, rock crushers, etc., will be installed in same. C. E. Smith, Franklin, president.

GOUVERNEUR—The Nestles Food Co. plans to remodel and reconstruct the plant which it purchased from the International Milk Products Co. last season. Additional equipment will be installed in same. Estimated cost, $100,000.

JAMESVILLE—The Farmers' Consumers Carbide Co., recently incorporated by F. M. Hennessey, 3rd National Bank Building, Syracuse, and others with $125,000 capital, plans to establish furnaces and calcium plant here. Estimated cost, $25,000.

LONG ISLAND CITY—The Famous Players-Lasky Corp., 485 5th Ave., New York City, has awarded the contract for the construction of a 3-story, 90 x 120-ft. laboratory and a 4-story, 100 x 200-ft. studio on Pierce, Graham, 5th and 7th Aves., to the Fleischmann Construction Co., 531 7th Ave., New York City. Estimated cost, $2,000,000.

LONG ISLAND CITY—The General Carbonic Co., 444 Van Brunt St., Brooklyn, has awarded the contract for the construction of a 1-story factory on 6th St. and West Ave., to the Austin Co., 217 Broadway, New York City. Plans include the installation of a chemical laboratory. Estimated cost, $200,000.

NEWARK—The city voted $280,000 bonds to build a gravity water supply system. Work includes pipe line involving 1750 tons of cast-iron pipe, 1,000,000 gallon rapid sand filtration plant, earth dam and dike, etc. J. P. Wells, Cutler Building, Rochester, consulting engineer.

NIAGARA FALLS—The Defiance Paper Co., Walnut and 3rd Sts., plans to build an addition to its pulp mill. Pulp grinders, rotary screens, etc., will be installed in same. Estimated cost, $18,000.

Ohio

CLEVELAND—The Harshaw, Fuller, Goodwin Co., Electric Bldg., has awarded the contract for the construction of a 1-story, 30 x 50-ft. addition to its varnish factory at 1002 Howard St., to the Hunkin-Conkey Co., 601 Century Bldg. Estimated cost, $15,000.

CLEVELAND—The Reflex Ignition Co., Superior Bldg., has awarded the contract for

the construction of a 2-story, 80 x 160-ft. factory on West 110th St. and N. Y. C. Railway, to S. W. Emerson Co., 1900 Euclid Bldg. Estimated cost, $65,000.

COLUMBUS—The Atlantic Refining Co., Hartman Bldg., plans to build a refinery.

COLUMBUS—The Columbus Pharmacal Co., 332 Oak St., plans to build a 3-story, 43 x 84-ft. factory. Estimated cost, $55,000. O. Darst, Brunson Bldg., archt.

MAUMEE—The State Board of Health has ordered the city to have plans prepared for a sewage disposal plant or trunk sewer to connect with Lucas Co. sewerage system to eliminate discharge of sewer into Maumee River. G. Champe, 610 Nasby Bldg., Toledo, engineer.

Oklahoma

CLAREMORE—The city plans election soon to vote on $82,000 bonds for sewer improvements, to include the construction of a sewage disposal plant, sanitary sewer extensions, etc.

EUFAULA—The city plans election soon to vote on $40,000 bonds to extend and improve the waterworks system, to include the installation of a Pittsburgh filtering plant at the pumping station as well as a 12-in. intake pipe.

Oregon

ASTORIA—The Astoria Pulp & Paper Co. has awarded the contract for the construction of a 40 x 250-ft. addition to its pulp and paper mill on 11th St. and Taylor Rd., to P. Trullinger. Estimated cost, $25,000. Noted Mar. 1.

CORVALLIS—The State Legislature has appropriated $60,000 for the construction of a 2-story, 56 x 220-ft. engineering laboratory at the Oregon Agricultural College here. J. V. Bennes, architect, Chamber of Commerce Bldg., Portland, preparing plans.

Pennsylvania

BETHLEHEM—The Traveler Tire & Rubber Co., 819 North Broad St., Philadelphia, plans to build a 2-story, 60 x 250-ft. rubber mill here. Estimated cost, $250,000. J. O. Hunt, 114 North Montgomery St., Trenton, N. J., architect.

CLARENDON—The Union Petroleum Co., Widener Bldg., Philadelphia, plans to rebuild the portion of its refining plant here recently destroyed by fire.

MONESSEN—The city plans to build an incinerating plant. A. J. Knight, president of the City Council.

Texas

FT. WORTH—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of an argon production plant here, to the Dawson Construction Co., 810 Union Trust Bldg. Estimated cost, $431,000. (180 days.)

FT. WORTH—The Creosoting Lumber Corp. plans to build a creosoting plant here, to have an initial capacity of 5000 barrels. Estimated cost, $75,000. E. Morrel, secretary.

STEPHENVILLE—The Duke Consolidated Oil Co. plans to build an oil refinery.

Virginia

NORFOLK—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will receive bids until April 21 for the construction of a galvanizing and oxy-acetylene plant here. Estimated cost, $108,000. Specification No. 2772.

West Virgina

MARTINSBURG—X. Poole and others plans to build dehydrating plant for apple products and is in the market for machinery for same.

Wisconsin

SHEBOYGAN—R. L. Frome, Howards Grove, has awarded the contract for the construction of a 2-story, 35 x 80-ft. glue factory on Calumet Drive, to R. Eisman. Estimated cost, $6500.

British Columbia

SLOCAN—M. S. Davys plans to improve existing plant and install a new concentrator. Estimated cost, $120,000.

Ontario

GUELPH—The Partridge Rubber Co., Ltd., Metcalfe St., plans to build a 3-story, 60 x 100-ft. factory. Estimated cost, $60,000. James, Loudon & Hertzberg, Excelsior Life Bldg., Toronto, engineers.

OTTAWA—The Ottawa Gas Co., Sparks St., plans to build a water-gas plant on Lees Ave., East Ottawa. Estimated cost, $850,000. A. A. Dion, 35 Sparks St., superintendent.

OWEN SOUND—W. Kennedy & Sons, 1114 1st Ave., West, plans to build an addition to its steel plant, to include the installation of equipment for two cupolas for smelting iron and elevators. Estimated cost, $85,000.

TIMMONS—The Hollinger Mines plans development, to include the construction of a plant and the installation of machinery. Estimated cost, $500,000. E. F. Brigham, engineer.

Quebec

TEMISKAMING—The Kipawa Co. plans to build pulp and paper mills. Estimated cost, $5,000,000. G. T. Lamb, Montreal, engineer.

Cuba

HAVANA—The Cuban Air Reduction Co., 120 Broadway, New York City, plans to build a 2-story, 98 x 108 ft. acetylene plant here. Estimated cost, $100,000.

Coming Meetings and Events

THE AMERICAN ASSOCIATION OF ENGINEERS will hold a meeting at 29 S. LaSalle St., Chicago, May 13 and 14.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 22nd annual meeting at Atlantic City, N. J., June 24-27. The headquarters will be at the Hotel Traymore.

THE AMERICAN ZINC INSTITUTE will hold its annual meeting at St. Louis, Mo., June 9-10, instead of May 12, as announced in our April 1 issue.

THE NATIONAL FOREIGN TRADE COUNCIL will hold its sixth national foreign trade council at the Congress Hotel, Chicago, Ill., on Thursday, Friday and Saturday, April 24, 25 and 26, 1919.

THE NATIONAL SERVICE COMMITTEE of the Engineering Council will hold a meeting at Chicago, Ill., April 23 to 25.

Industrial Notes

Organization of Electric Furnace Association

At a meeting held at Niagara Falls on March 21 and 22 an organization was perfected to promote the use of electric-furnace products. The organization is known as the Electric Furnace Association and comprises manufacturers of electric furnaces, electrical apparatus, electric-furnace supplies and accessories, designers and inventors of electric-furnace equipment and the users of electric furnaces. The purpose of the organization is to lay before the consumers of electric-furnace products the advantages of those materials. Special emphasis was laid on electric steel, the tonnage of which showed remarkable increase throughout the world during the last four years.

The meeting was attended by representatives of the General Electric Co., Westinghouse Electric and Manufacturing Co., American Metallurgical Corp., Industrial Electric Furnace Co., T. W. Price Engineering Co., Booth-Hall Co., Hamilton & Hansell, Ludlum Electric Furnace Co., Pittsburgh Electric Furnace Co., Fitz-Gerald Laboratories, Carborundum Co., Norton Co. and Acheson Graphite Co.

A permanent organization was created with the following officers: President, Acheson Smith, Acheson Graphite Co., Niagara Falls; first vice-president, C. H. Booth, Booth-Hall Co., Chicago; second vice-president, W. E. Moore, Pittsburgh Electric Furnace Co., Pittsburgh; secretary, C. G. Schluederberg, Westinghouse Electric & Manufacturing Co., Pittsburgh; treasurer, F. J. Ryan, American Metallurgical Corp., Philadelphia; directors, the officers and C. A. Winder, General Electric Co., Schenectady, and F. J. Tone, Carborundum Co., Niagara Falls.

Committees were created as follows: Publicity: C. H. Booth, chairman, C. A. Winder, C. G. Schluederberg and A. B. Oatman. Data: W. E. Moore, chairman, J. A. Seede, A. M. Williamson, F. J. Ryan, F. A. J. FitzGerald and C. A. Vom Baur. Fields: F. T. Snyder, chairman, F. J. Tone, H. A. DeFries and S. L. Walworth.

The second meeting was held in New York April 3, at which the tentative draft of the constitution and by-laws was adopted. An aggressive campaign for members was planned to include all manufacturers of electric furnaces, electric-furnace supplies, electric steel, electric brass, electric power and designers and inventors of furnaces.

THE STURTEVANT MILL CO., Boston, Mass., announces the establishment of new offices, at Room 619 Singer Bldg., 149 Broadway, N. Y. C. These offices are in charge of the company's former Western sales manager, Mr. J. S. Vrabek, recently promoted to the position of Eastern sales manager.

THE NEWARK TECHNICAL SCHOOL, Newark, N. J., announces a special course in corporate chemistry by Dr. Frederic Dannerth. The aim will be to show the application and the principles of industrial chemistry to manfacturing problems. It will cover:

1. Sources of raw materials.
2. Executive departments, purchasing, manufacturing and selling.
3. Advisory departments, engineering, law and research.
4. Laboratory management.
5. Economic office organization management.

Further details can be obtained from Mr. D. R. Hodgdon, director.

A. P. GREEN FIRE BRICK CO., Mexico, Mo., has opened an Eastern district sales office at 30 Church St., New York City. Mr. Howard C. Thayer, formerly field mechanical engineer for the J. G. White Corp. at the U. S. Nitrate Plant No. 2, is in charge.

THE STEPHENS-ADAMSON MFG. CO. of Aurora, Ill., has recently established a new sales office in Cincinnati, Ohio, to give attention to this particular territory. Mr. John G. Stewart, who has been associated with the Stephens-Adamson Manufacturing Co. for fifteen years, had been appointed district manager.

CHARLES F. AMES CO., 90 West St., New York City, has been appointed to act as the New York sales department of the Platt Iron Works, Dayton, Ohio.

THE PHOENIX IRON WORKS CO., Meadville, Pa., has opened a New York office, Room 619, Fifth Ave. Bldg., in charge of Mr. J. E. Kindregan and Mr. Paul C. Rodgers. Mr. Kindregan continues representing this company as district sales manager, with an office in the Harrison Bldg., Philadelphia, Pa., and will devote only a part of his time in the company's interest at New York. In addition to the New York territory, Mr. Rodgers will also continue the representation of the company at Boston.

MR. HERMAN A. HOLZ has moved his office and laboratories to the Pullman Bldg., 17 Madison Ave., New York City. The laboratories will contain equipment for experimental heat-treating, hardness and impact testing, micro- and macro-photographic investigation of metal sections, apparatus for magnetic measurements and for investigating the mechanical properties of steel products by determination of their correlated magnetic characteristics, also equipment for X-ray work on metal products.

THE ISLAND REFINING CO., a subsidiary of the Island Oil & Transportation Co., has been formed to refine the oil of the latter company, which has a potential production of 35,000,000 bbl. of oil per year. Col. G. A. Burrell of Pittsburgh, Pa., has been elected president of the new company.

THE U. S. COPPER PRODUCTS CO., Cleveland, Ohio, has placed an order with the General Electric Co., Schenectady, N. Y., for a brass-melting furnace of the muffled arc type having a capacity of 2200 lb. per hour.

THE ASPROMET CO. of Pittsburgh, Pa., announces that the name of the company has been changed to the H. H. Robertson Co.

OSAKA BOEKI KAISHA, LTD., Osaka, Japan, solicits correspondence with American dealers in chemicals and metals with the object of securing Japanese and Korean representation of American lines.

JOSEPH BOUKEZ & CIE, Alexandria, Egypt (address P. O. Box 604), general importers specializing in chemicals, iron and steel, cement and building materials, desire representation of American lines.

THE W. A. JONES FOUNDRY & MACHINE CO., of Chicago, Ill., manufacturers of power transmission apparatus, special foundry and machine work and also the Jones spur gear speed reducer, have opened an Eastern office at 30 Church St., New York, under the direction of Mr. Lemuel C. Biglow, who formerly for a number of years held a similar position with the Morse Chain Co., of Ithaca, New York.

THE METAL & THERMIT CO., New York City, is issuing a large map calendar showing the new railroad time zones in the United States which went into effect Jan. 1, 1919.

THE AIR REDUCTION SALES CO., New York, at the organization meeting of directors held Feb. 19, 1919, elected the following officers: Mr. A. S. Blagden, president; Mr. A. R. Ludlow, vice-president; Mr. C. E. Adams, treasurer; Mr. M. W. Randall, secretary; Mr. C. L. Snow, assistant treasurer; Mr. C. C. Emerson, assistant secretary.

THE NATIONAL ANILINE & CHEMICAL CO., New York, held its annual meeting of stockholders and a subsequent meeting of directors on Feb. 17 and 19 respectively. Officers and directors were elected as follows: President and chairman of the board, William J. Matheson; vice-presidents, Dr. William Beckers, Robert Alfred Shaw and Dr. L. C. Jones; acting treasurer, William H. West; assistant treasurers, H. S. Trott and T. S. Baines; secretary, William T. Miller; assistant secretary, Walter E. Rowley; chairman of executive committee, Henry Wigglesworth. The personnel of the board is as follows: Dr. William Beckers, New York; H. H. S. Handy, Syracuse; Dr. L. C. Jones, Syracuse; Clinton S. Lutkins, New York; William J. Matheson, New York; Eugene Meyer, Jr., New York; W. N. McIlravy, New York; F. M. Peters, New York; T. M. Rianhard, New York; Robert Alfred Shaw, New York; I. Frank Stone, New York; Dr. P. C. Taggesell, Buffalo; Orlando F. Weber, New York; Henry Wigglesworth, New York.

DR. EMIL E. LUNGWITZ, chemical and industrial engineer, 90 West St., New York City, has opened an office at 14 East Jackson Blvd., Chicago, Ill., under the management of Mr. H. L. Dick.

THE EPPING-CARPENTER PUMP CO., Pittsburgh, Penn., announces the appointment of Mr. P. S. Healey as manager of sales in addition to his former office of chief engineer. Mr. F. F. Woods is now located in New York as Eastern sales manager. Mr. Albert A. Scheuch of the sales department has been appointed as assistant sales manager, and Mr. Paul D. Goodman, formerly of the McClary Jemison Machinery Co. of Birmingham, Ala., has been added to the sales personnel.

THE BROWN-STEEL CO., Columbus, Ohio, has been incorporated to take over the steel department of the Columbus Mill & Mine Supply Co. of that city.

THE BECKWITH MACHINERY CO., Arch St. and Parkway, Northside, Pittsburgh, has opened an office and warehouse at 1227 West 9th St., Cleveland, for the sale of the regular lines of mine, mill and construction equipment marketed by this company.

BARZILLAI G. WORTH, vice-president of Walter Kidde & Co., Inc., has been elected treasurer of the Monmouth Chemical Co., also having charge of manufacturing and research. This company produces potassium chlorate electrolytically, using processes and apparatus developed by Walter Kidde & Co., Inc., under Mr. Worth's direction. During the war and at the instance of the United States Government Mr. Edward Schwarz, chemical engineer of the Kidde organization, succeeded in developing for the Monmouth Chemical Co. a new bromate-free chlorate product surpassing the German standard. This was done in co-operation with the work of the Ordnance Department to eliminate the causes for ammunition failures reported to Congress in the early stages of the war by Secretary Baker.

THE HYDRO ELECTRIC POWER COMMISSION, Ontario, Can., placed an order with the Westinghouse Co., for two 45,000 k.v.a. vertical water-wheel generators of 12,000 volts, 3-phase, 25-cycles, for their Queenstown development. These will be the largest water-wheel generators ever constructed.

THE ATMOSPHERIC CONDITIONING CORP. of Philadelphia, Penn., is the new name of the organization which, after Apr. 1, will manufacture and market the air conditioning apparatus and the Webster system of humidifying control formerly handled by the Braemer Air Conditioning Corp. The equipment includes Webster air washers, humidifiers, dehumidifiers, generator coolers, etc. The officers of the new corporation are: Mr. John F. Hale, president; Mr. William J. Strandwitz, vice-president; Mr. Herbert A. Terrell, secretary and treasurer; Mr. E. Nesdahl, chief engineer. Mr. Warren Webster, president and general manager of Warren Webster & Co., is a member of the board of directors. Territorial officers are already established in many of the larger cities of the United States and Canada and also in London, England.

New Publications

Tycos Tables is a publication recently gotten out by the TAYLOR INSTRUMENT COMPANIES, Rochester, N. Y. This new edition gives general data concerning and for use with temperature indicating, recording and controlling instruments; hydrometers and meteorological instruments. Price, $1.00.

NEW BUREAU OF STANDARDS PUBLICATIONS: Scientific Paper No. 332. Preliminary determination of the thermal expansion of molybdenum. By Lloyd W. Schad and Peter Hidnert; Circular No. 78. Solders for aluminium; Technologic paper No. 118, A critical study of the Ledebur method for determining oxygen in iron and steel. By J. R. Cain and Earl Pettijohn.

NEW BUREAU OF MINES PUBLICATIONS: Tech. Paper 196. Notes on the black sand deposits of Southern Oregon and Northern California. By R. R. Hornor; Bull. 172. Abstracts of current decision on mines and mining. By J. W. Thompson; War Minerals Investigations Series No. 9, Problems involved in the concentration and utilization of domestic low-grade manganese ore. By Edmund Newton.

THE MINES EXPERIMENT STATION AND ITS RELATION TO THE IRON MINING INDUSTRY OF MINNESOTA. Published by the School of Mines, University of Minnesota, Minneapolis, Minn., Feb., 1919.

MANGANESE AND CHROMIUM IN CALIFORNIA. By Walter W. Bradley, Emile Huguenin, C. A. Logan, W. Burling Tucker and Clarence A. Waring. Bulletin 76, dated August, 1918, published by the California State Mining Bureau, San Francisco, Calif.

QUICKSILVER RESOURCES OF CALIFORNIA. By Walter W. Bradley of the California State Mining Bureau. This is Bulletin No. 78, and is the first work published in 15 years dealing distinctly with quicksilver and its metallurgy. It includes an account of the original investigations on concentration of quicksilver. Copies may be obtained for $1.50 postpaid, from the State Mining Bureau, Ferry Bldg., San Francisco, Calif.

THE FEDERAL BOARD FOR VOCATIONAL EDUCATION is issuing a series of "Opportunity Monographs," dealing with various forms of employment for disabled soldiers and sailors. The purpose of the series is to give these men the information that will assist them in choosing a vocation. Monographs have been published on the following subjects: Series No. 6, Safety and Fire Protection Engineering; Series No. 9, Oxy-Acetylene Welding; Series No. 13, Concrete Construction and Cement Manufacture; Series No. 14, Electrical Employments with Utility Companies; Series No. 15, Electrical Construction, Maintenance, and Repair Occupations; Series No. 16, The Law as a Vocation.

CANADIAN DEPARTMENT OF MINES PUBLICATION: Preliminary Report of the Mineral Production of Canada During the Calendar Year 1918. Prepared by John McLeish, published Feb. 27, 1919.

Manufacturers' Catalogs

THE ESTERLINE CO., Indianapolis, Ind., publishes each month the "Esterline Graphic." The pamphlet on hand deals with power factor surveys, which is of special interest to central stations and industrial plants. This company will be glad to send to anyone interested information on graphic recording instruments of the portable, wall or switchboard type.

THE W. S. ROCKWELL CO., 50 Church St., New York, is distributing Bull. 41 to interested parties, upon application. This bulletin covers the subject of heating furnaces for billets, wire bars and cakes. The text and illustrations aim to give a comprehensive account of the heating operations involved, including suggestions as to the types of furnaces found best suited to various plant and manufacturing requirements.

THE WHEELER CONDENSER & ENGINEERING CO., Carteret, N. J., has published preliminary Bull. 113, illustrating and describing a steam jet air pump containing two or more steam jets working in series with a condenser between the jets. The bulletin gives engineering data on the operation of the pump.

THE SEMET-SOLVAY CO., Syracuse, N. Y., calls attention to a new catalog on Solvay protective paints. This 32-page booklet deals with crysollite protective, graphite, stack, acid-resisting and hydraulic paints, concrete coatings and general directions about the use of these materials. Price list No. 53 is supplemented with the booklet.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis.: "C-H Molded Insulation" is the title of a new 2-color, 16-page booklet which describes thermoplax and pyroplax, the trade names of the heat-resisting and fire-resisting Insulations made by this company which can be molded into countless sizes and shapes for all purposes.

THE AMERICAN-LA FRANCE FIRE ENGINE CO., INC., Elmira, N. Y., has issued a Safety-First catalog, Edition D, which deals not only with the first aid to the injured, but also with resuscitation, safety signs, respirators, masks, pure air helmets and hoods, and many other appliances for the protection of workers, giving illustrations as well as descriptive matter. The "ambrine" surgical dressing is noted, first-aid equipment and cabinets are illustrated and described, also an improved stretcher and other equipment such as rubber gloves, leggings, protective suits, safety oil cans, portable lamps, etc., which devices all make for the preservation of life, health and property.

National Integrity, Personal Responsibility and the Victory Loan

OUR soldiers are coming home. On April 25 over 23,000 arrived in New York harbor, and each day sees thousands more returning to resume their places as civilian workers. Hundreds of thousands still remain in Europe to finish the job they started; and seventy thousand, more or less, who represent the price in human life which the United States paid for world peace, sleep under the little white crosses that mark our soldiers' graves in France. Upon us devolves the welcome duty of paying the money debt incurred by the vast preparations necessary to support those thousands who are now returning, and those other thousands who made the supreme sacrifice.

Speaking of sacrifice, how little the average American citizen knows about it in connection with the war. None went hungry or naked; all slept peacefully, secure from invasion, pillage or death; few gave up luxuries and fewer still denied themselves necessities; except for a few gasless Sundays, our automobiles worked about as usual; Liberty bonds were bought out of our abundance, and created a bigger capitalist class than the country ever knew before. We knew not the terror of the air raid or the long-range bombardment, nor did we see the flower of our youth fall by the million in battle until our whole nation was in mourning. It is scarcely becoming to speak of sacrifice on the part of the majority of our people.

The work is yet to be finished, and the Victory loan is made for that purpose. As portrayed in the colored supplement to this issue of CHEMICAL & METALLURGICAL ENGINEERING, Liberty makes this final appeal in the name of those whose graves dot the soil of France.

Has Heat Treatment Been Demonstrated?

ONE is accustomed, when thinking of things connected with the manufacture of modern machine parts, to assume that heat treatment actually has been demonstrated. That is to say, that factory or shop executives universally recognize the fact that the physical properties of metallifactures may be altered and adjusted by a properly selected schedule of heating and cooling.

But evidently not so! A case in point occurred in the year of grace 1918, in a shop belonging to a huge Western railroad system. The mechanical engineering authorities were evidently wide awake; they knew the elastic limit and ductility required for various engine repair-parts, and these properties were specified and obtained. The forge shop was well in line, too; for instance, when making locomotive driving rods, special attention was given to produce a finished piece which would forthwith pass the rather exacting physical re-

quirements, and in order to reduce the discouragingly large number of rejections, the foreman had installed a pyrometer in his heating furnace, which was carefully kept at a certain reading.

Still rejections were even at best all too common—perhaps two for every good rod produced. Of course these beautiful heavy forgings were not altogether lost, for some economical body decided to cut them up for smaller pieces of less importance whereby many dollars were saved to help Uncle Sam win the war!

One day a metallurgist from a steel company was at these shops endeavoring to adjust a purchasing-department claim. He noticed a big side-rod in process of demolition and on inquiry discovered the conditions just outlined. Being naturally curious, he inquired why an effort was not made to adjust the physical properties of the completed forging by an anneal, and was startled by the information from the shop superintendent, "One of our men thinks that some of them might be passed in that way, but heat treatment is still in the experimental stage and we are in no position to monkey with it. All our energies are required for production." This certainly was a poser, but the inquisitive visitor was militant as well, and on a long-odds wager, placed three excellent but rejected rods in an end-fired tunnel furnace —the only thing immediately available—turned on the flame, heated them until one portion began to color, then let them soak for a time, and repeated the process until the bars had gradually passed the transformation range —judging temperatures entirely by eye. After cooling from this crude operation, fresh tests from the forgings passed the ductility limit easily.

The foreman paid the wager with a smile, as well he might, since the gain was a hundred dollars for each one lost, yet he retains the original practice! What will get beneath the skin of "rule-of-thumb," "practical" methods, anyway?

Bolsheviks and Research

PROBABLY few would dispute the assertion that there is no industrial research now under way in bolshevik Russia. True, the civilized world lacks definite knowledge as to this and other particular points, but by inference the statement is approximately correct. If a governing body decides that executives of industrial enterprises are excrescences on the body politic to be forthwith lopped off, surely the workman-managers do not need a bespectacled scientific staff to tell them how to improve process, performance or production.

Americans, especially Americans who are managers or directors, think of bolshevism and soviets as a child thinks of bogey-men, and any one of them would hotly resent any insinuation that his mental processes were bolshevikian—devil take it and all its works! But in more than one recent instance, such a manager or such a director has started to "reduce the cost" of his product by eliminating that most essential part of his technical organization, the research staff. A bolshevist would have pushed his mistaken idea to the limit, though. He would have fired the manager, the auditor, and even the director himself. The insinuation is, therefore, immediately withdrawn.

Doubtless it is only reasonable to presume that research organizations instituted during the affluence of war-times should be regarded as non-essentials, and their appropriations refused before their work was well under way, when the product is not selling with its former ease and volume. Such a research was instituted, not because the management realized the need for it, but because it was stylish, or because the concern had more money than it cared to turn over to Uncle Sam. Luxuries and side issues can now be dispensed with, it is true; but it is truer that properly organized research is neither a luxury nor a side issue.

It is almost an axiom derived from experience that the surest way to increase the use of an article is to cheapen its cost so that it can be marketed at a lower price. Now in the ultimate analysis, the cost of any article, no matter how simple or how intricate, depends upon the money spent for labor and the money absorbed by capital, taxes or royalties—in brief, for "labor" and for "capital." At times even the directors have aimed to reduce costs, always by the doubtful expedient of cutting labor rates, seldom touching capital costs except as a last resort. The technical management, on the other hand, often has the best will in the world to reduce labor costs by increasing the efficiency of the men and machines, but, pray, who is to point the way in which more production can be had from a dollar's worth of raw materials or an hour's human labor, if it is not the research department?

This argument is almost self-evident to the technical man. It may happily reach and convince the executive. His conversion would doubtless be easier if he could realize that by increasing labor and technical efficiency is found the only way in which present capital charges can be maintained. But human nature is the same everywhere—even in high places they buy dear on a rising market, and scramble to sell when things are cheap!

The Way to Prosperity

LET us try to clear the industrial atmosphere with a few plain truths. First: We are not going to return to pre-war conditions, economically, socially, industrially or commercially—nor do we want to. Second: Economic law is as basic and sound as scientific law or engineering fact, and disaster is quite as certain to overtake those who violate the one as those who ignore the other. Third: The people now need education in economics even more than prior to the war, so that certain fundamental facts will be widely understood and appreciated. Fourth: Failure to realize and accept the changes, and ignorance of their cause, is largely responsible for the lull in business activity—the valley of depression in the curve of industry and commerce; conversely, a knowledge of fundamentals would remove hesitancy, uncertainty and gloom, and enable business to step forward with confidence and cheerfulness.

Fortunately for all of us the voices of the economist and sociologist are being heard in the land, but they need reinforcement and transmission to a larger audience. It seems scarcely necessary to attempt to prove that pre-war conditions generally have gone for good. The war itself was a social revolution, a protest against autocracy in politics. Is there anything startling in the corollary that autocracy likewise must be removed from industry? This explains the social unrest, the aspirations of the worker, the necessity for recognizing a new order in human relations. Likewise the war caused an inflation of currency and credit that is responsible for the high prices of commodities, and the establishment of a permanent new high-price level in

business. Prices are not going back to pre-war levels, as a general proposition, and wages must remain high in order to meet the increased cost of living. There will be changes until the most glaring discrepancies are removed, but in general prices and wages are up to stay. If the changes are proportionate, we are all just as well off as before. The great necessity is to realize the futility of talking about lower prices and wages or waiting for them to come.

In an analysis of the causes for present prices, MR. O. P. AUSTIN, statistician for the National City Bank, New York City, finds that the first contributing cause was a "scarcity demand" for war materials. This cause, however, would not explain the concurrent rise in prices of commodities that found no place in war and for which no war demand existed. Looking deeper into the matter, he finds that world inflation of currency is the fundamental cause, paper money with a face value of $36,000,000,000 having been issued by the countries at war, excluding the currency issued by the bolsheviki. Practically all of this is an acceptable medium of exchange in the country of its origin. Add to this the $180,000,000,000 of bonds that the responsible nations of the world have issued, and which are in effect a basis for obtaining money; and the $50,000,000,000 increase in world bank deposits, and we are not surprised when MR. AUSTIN pertinently observes:

"If the world's historians and financiers and economists and statisticians are right in their general belief that any advance in prices usually accompanies or closely follows inflation in currency, and especially in paper currency, can we be surprised at the world-wide advance in prices which we have witnessed during the past four years in which world currency and bank deposits trebled and national debts quintupled?"

Deflation is not in sight, and that is the only hope for materially lower prices. Isn't it about time to rely upon the laws of economics and go ahead with business? The question answers itself. Intelligent conclusions drawn from the facts point irresistibly toward resumption of business, realizing that the change that has taken place is one of degree only, and that the great need of the hour is a combination of optimism and wisdom that will bring about resumption by resuming.

Alignment of the Steel Industry

THE steel industry has been the "prince or pauper" industry so long and it has so generally been regarded "the barometer of trade" that we have insensibly fallen into the habit of regarding it as a foregone conclusion that if business is good the steel industry will thrive, while if business is not good the steel industry will languish. That is, the steel industry has nothing to do with its own destiny. It is assumed to come about naturally that the industry is too small when times are good and too big when times are bad. After all, however, it would be decidedly curious if such a doctrine should work out right all the time.

On the one hand, the war caused the American steel industry to expand greatly, productive capacity having increased by fully 40 per cent since 1914. On the other hand, the war stopped nearly all construction work, and it is in construction work that steel finds its chief demand. It is true that tin cans are used but once, that wire fence rusts away and that some steel is used in making tools, automobiles and various things that have but a limited life. The heaviest employment of steel is in construction works, which are established as investments, in bridges, factories, hotel and office skyscrapers, power plants, transmission lines, oil and gas pipe-lines and similar enterprises. What is the balance between the increase in steel-making capacity and the halt in construction work, both caused by the war?

Existing capacity should be compared with production or consumption before the war rather than with capacity at that time. In the five years, 1905 to 1909 inclusive, the production of steel ingots in the United States averaged 20,325,000 tons a year. In the next five years, through 1914, the average was 26,313,000 tons. Capacity at present is about 50,000,000 tons.

Plainly this is a very large increase to be taken care of. It is true that pig iron production has very nearly doubled every ten years, while the production of steel has increased somewhat more rapidly; but if it were possible to divide all steel consumption, year by year, into transitory and permanent use, into classes represented respectively by tin cans and beams, it would probably be found that the latter class has increased more rapidly than the former. No point is strained, by the way, in using the tin can as an illustration, for the production of tin plate in the past two years has been at a greater rate, in point of tonnage, than the production of all structural shapes in any year prior to 1905.

The demand for steel for construction purposes rests upon no whim, but upon a collection of very definite factors. In essense, the steel is bought by an investor, who does some careful figuring. He estimates what the property will return in annual earnings, and makes allowance for amortization. He considers the cost of the steel, the cost of the other materials that must be used at the same time, and the cost of the labor necessary to convert the steel and other materials into the final work. Then he checks up the whole matter by estimating how much the same thing would cost one year or two years hence. If a saving in first cost is shown, that has its own value, and there is coupled with it the fact that one year or two years hence the investor will have clearer vision as to the future earning power of the investment.

As to steel demand in the remainder of the world, the comparison between the American and foreign industries is favorable in one respect and unfavorable in another. Taking the American steel industry as representing 50,000,000 tons of ingots a year, the British industry is between 20 and 25 per cent as large; the French industry, cut in half by the war, and to be reconstituted but slowly, represents not much over 5 per cent; the German industry represents between 15 and 20 per cent, and the Belgian industry is practically destroyed. The total is hardly more than 40 per cent, apart from capacity in Canada, Japan, India, Italy, etc. If the world wants much steel it must come to the United States, and in that respect the alignment is very favorable. On the other hand, the production of the whole world before the war, excluding the United States, was less than 44,000,000 tons of ingots. Including material received from the United States the world got along with an amount of steel less than the present capacity of the United States. It was not a prodigal user of steel as the United States has been, and in that respect the comparison between steel capacity in this country and conditions outside this country is unfavorable.

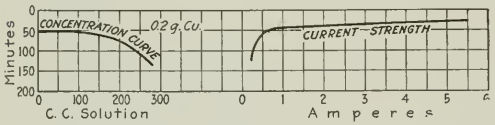
Rapid Electrolytic Copper Assay Without Rotating Cathode

To the Editor of Chemical & Metallurgical Engineering

SIR:—Nearly all apparatus for electrolytic analysis on the market is equipped with a motor and revolving cathodes. This enables the agitating of the electrolyte while the metal is being deposited, and is a distinct advantage. The solution is stirred and fresh copper ions come in contact with the electrode continually. Also any hydrogen bubbles formed on the cathode are broken by the agitation, thus eliminating the danger of spongy copper being formed. Moreover, under these conditions, a very much higher current density can be used than otherwise would be possible and insteal of leaving your assay over night you have it done in a few minutes.

However, even without this elaborate equipment it is possible to perform this assay quickly if precisely the proper conditions are obtained. As chief chemist



for the Vermont Copper Co., at South Strafford, Vermont, I conducted a number of experiments along this line and the following was found to be the best method of procedure.

A sample on the ore was decomposed in 5 cc. each of HNO_3 and HCl, heated nearly to dryness, and then 5 cc. of H_2SO_4 was added and heat applied until SO_3 fumes were freely evolved. The residue was cooled, diluted, 1 cc. of HNO_3 added to break up the anhydrous ferrous sulphate, boiled, cooled and filtered to remove insoluble. The filtrate was then placed under the electrodes and the copper precipitated. After precipitation the cathode was washed in water and then in alcohol, and then burned over a free flame before weighing.

The Winkler type of cathode was used, which in this case was constructed of a cylinder of platinum gauze 3 cm. in diameter and 6 cm. in length. The gauze was composed of wires 0.06 mm. in diameter with forty-one meshes per linear centimeter. The anode used was simply a spiral of No. 16 platinum wire hung inside the cathode. With this arrangement rapid deposition was effected and no trouble with spongy deposits was encountered.

Another fact that facilitated rapid work was the quantity of solution used. The accompanying graph shows the result of a series of experiments. However, I found 100 cc. to be the minimum amount of solution I could use without having the solution so concentrated that it would dissolve up the copper faster than it was precipitated.

The other graph shows the result of varying the current strength. I believe the conclusions are self-evident.

The cost of making assays by this method was 30c. each. This figure includes cost of materials, labor, interest on cost of laboratory equipment, and depreciation.

The Perchloric Acid Method for Potash in Cement Materials

To the Editor of Chemical & Metallurgical Engineering

SIR:—Since the almost prohibitive cost of platinum salts has made the determination of potash by the old method quite an expense to those who, like the cement chemists of to-day, have frequent occasion to determine K_2O, analysts have turned to other methods which may be substituted for that employing platinic chloride, and two are in common use, the cobalti-nitrite and the perchloric acid methods.

The former is held by many authorities to be unreliable and is also somewhat complicated, though it is capable of giving excellent results if carefully performed, but the perchloric acid method has lately sprung into prominence through the possibility of obtaining perchloric acid (60 per cent solution) in pure form at a reasonable price.

The manufacturers of this acid give directions for its use in potash determinations which are satisfactory as regards water-soluble potash, but they say nothing of the *modus operandi* when *total* potash is required, as it often is in such materials as shale, clay, flue dust, etc., which, being silicates in whole or part, require fusion before they can be brought into solution.

The writer has found that the determination of water-soluble potash by the perchloric acid method is simple, rapid and accurate. The substance is boiled half an hour with excess of water, filtered, and the filtrate acidified with HCl. Sulphates are precipitated as $BaSO_4$ and removed by filtration, and calcium is precipitated in the filtrate by ammonium carbonate and a little ammonium oxalate. These reagents are both volatile at a low heat, so that when the filtrate from the carbonate precipitate is evaporated and the residue moderately heated, ammonium salts pass off, leaving nothing remaining but chlorides of potash and soda. These salts are converted into perchlorates by a little perchloric acid and separated by alcohol, which dissolves the sodium perchlorate, but leaves the potassium perchlorate undissolved, and the latter can be readily collected on an asbestos filter and weighed.

The treatment of flue dust, etc., for total potash is necessarily more complex, but presents no difficulties. Of course, ordinary fusion with carbonates to break up the silicates is not permissible, as this would introduce large proportions of soda and probably some potash, which would obscure the result, so it is best to adhere to the J. Lawrence Smith fusion with ammonium chloride and calcium carbonate preferably in a long platinum crucible. After digestion of the charge in water the excess calcium carbonate is filtered off, the filtrate acidified with HCl and treated exactly as the first filtrate in the water-soluble determination.

The writer has found that most flue dust contains

organic matter which necessitates filtration after driving off the ammonia salts by heat, that is, before evaporating the solution of sodium and potassium chlorides with perchloric acid. Otherwise the operations for total and water-soluble potash are identical after the first solution is obtained. In detail the method employed in our laboratories is as follows:

For Total Potash. Grind ½ g. of the sample (flue dust, shale, etc.) with ½ g. ammonium chloride in an agate mortar. Add 4 g. of pure calcium carbonate and grind thoroughly together. Put a little calcium carbonate in bottom of J. Lawrence Smith crucible, add the charge with 1 g. calcium carbonate on top, cover and heat with a low flame till there is no further odor of ammonia (15 min.). The heat must not be high enough to permit the escape of visible fumes. Then raise the heat to moderate redness for 45 min., turning crucible occasionally. Cool, dissolve the melt in a little water, carefully rinsing the crucible. Slake on water bath, breaking up lumps. Filter off excess calcium carbonate, wash and make filtrate strongly acid with HCl. Boil and add slight excess of barium chloride. Let stand preferably several hours. Filter off the barium sulphate, wash, heat the filtrate to boiling and add ammonia till alkaline, and ammonium carbonate until no further precipitate forms. Add a few drops of ammonium oxalate, filter and wash. Evaporate the filtrate to dryness in a platinum dish and when dry heat carefully to just below redness till all ammonium chloride fumes are gone. Cool, dissolve in 25 cc. hot water, filter off anything undissolved and add to the filtrate enough 60 per cent perchloric acid solution to convert all the alkali metals into perchlorates (ordinarily 1 cc. is enough). Evaporate until nearly dry and when heavy fumes of $HClO_4$ appear cool, add 25 cc. hot water, another cc. perchloric acid and evaporate again to the same point. Cool, add 25 cc. wash alcohol (containing 1 cc. perchloric acid solution to every 300 cc.), filter on asbestos in a Gooch crucible, wash with the same alcohol, dry and weigh as $KClO_4$.

In washing the precipitates it is unnecessary to wash them entirely chlorine free; for ordinary work three or four washings are sufficient. The barium chloride, ammonium carbonate and ammonium oxalate mentioned are all used in saturated solutions.

For Water-Soluble Potash. Five grams of the sample are boiled 30 min. with 150 cc. water in a small flask with condensing tube. Cool. Make up to 250 cc., mix well and filter through a dry paper without washing. Take 50 cc. of the filtrate, corresponding to 1 g. of the sample, acidify strongly with HCl and proceed as in the determination of total potash given above. Multiply weight of potassium perchlorate found by 33.935 for per cent of K_2O in sample. WILLIAM B. NEWBERRY.

Sandusky Cement Co.,
Cleveland, Ohio.

Credit to Whom Credit Is Due

To the Editor of Chemical & Metallurgical Engineering

SIR:—I read, with great interest, an article in your issue of April 15 by the Messrs. H. E. and C. E. Hollister regarding the great acid plants of the Government powder plant, and it seems to me as if everybody comes in for some mention for his particular part in this great undertaking, from the lowly shoveler to the superintendent. But there is one branch with which I had the pleasure of being connected and which I know put forth its best efforts in connection with this work and seems to have been completely ignored. This branch was the resident engineers' department of the Thompson-Starrett Co. under Mr. A. E. Barlow, who supervised the entire field work of the areas mentioned in your article, and labored from sunrise to sunset, rain or shine, to lay out the work so that construction could be carried on. Mr. Geo. Uhden was the engineer directly in charge of Area "B" and Mr. Fred Petzold in Area "C."

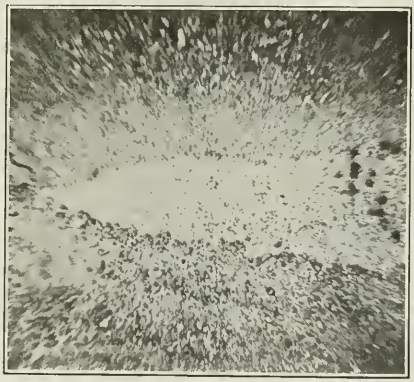
In justice to the above-mentioned branch of the organization and its members I think this letter should receive as much publicity through your columns as the article which so completely ignored them.

Brooklyn, N. Y. FRED PETZOLD.

Flakes in Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—In my paper on Flakes in Steel in your April 1 issue a correction should be made. On page 351 the phrase on line 34 from the top reads: "Another possible cause for flake may be segregated spots such as are exhibited by the variable-hued grains in Fig. 23."



This is wrong. The expression refers to a picture which was not reproduced and of which I enclose a copy. The variable hued grains in Fig. 23 do not, in my opinion, cause flakes. Fig. 25 shows the same kind of differently hued grains and is from a bar practically free from sign of flake. HAAKON STYRI.

Carnegie Institute of Technology,
Pittsburgh, Pa.

Bids Requested on Chlorine

Sealed proposals in duplicate addressed to Paints Branch, Raw Materials Division, Munitions Bldg., Washington, D. C., are desired on 6500 lb. of liquid chlorine, bidders to specify size of container and quote price f.o.b. Camp Merritt, N. J.

Standard Form for Mexican Claims

The State Department at Washington announces that a standard form has been prepared for filing claims against the Mexican Government. It is expected that the final form will be prepared for approval by the middle of May, at which time copies will be sent to those who have claims in order that they may be resubmitted. The new form will supersede all previous ones.

Western Chemical and Metallurgical Field

Cost of Quicksilver and Fulminate

ANY attempt to estimate the cost of metal production is likely to be misleading, since conditions vary so much from district to district, while even with identical mining and metallurgical practice and efficiency, the cost per unit varies immensely with the tenor of the ore. F. C. Ransome, in a recently issued Geological Survey publication on quicksilver, has estimated the labor required to produce mercury in American mines during 1917 as follows:

RELATIONS OF QUICKSILVER PRODUCTION TO LABOR IN CALIFORNIA AND TEXAS

	California		Texas,
	All Mines	Eight Leading Mines	Three Mines
Ore treated, short tons	235,786	203,449	26,802
Quicksilver produced, flasks	23,938	18,581	10,530
Tenor won	0.38	0.34	1.47
Average number of men employed	950	715	253
Man-days of work	310,500	233,689	84,795
Quantity of ore treated per man, short tons	248.1	322.8	105.9
Quantity of ore treated per man-day, short tons	0.75	0.99	0.32
Quicksilver obtained per man annually, flasks	25.1	26.0	41.6
Quicksilver obtained per man-day, flasks	0.077	0.079	0.124

On this basis he estimates that in 1917 the average cost, including development and amortization, of producing a 75-lb. flask of mercury in California from 0.38 per cent ore was from $65 to $70. The cost in Texas was lower, due to its average content of 1.43 per cent. Spanish mines in Almaden made $12 quicksilver from 9.04 per cent ore in 1915. Monte Amiata in Italy produced mercury for about $30 in 1913 from 0.89 per cent ore, while the pre-war cost at Idria, Austria, was $23 per flask from 0.65 per cent ore.

While the foregoing figures are as of 1917, it is entirely safe to assume that costs of production in California and Texas have not dropped in the meantime, so with the present San Francisco price of $70 per flask it is easy to understand the closure of some California quicksilver mines and the curtailment of operations of others. During the war the developed ore reserves and ore dump were nearly exhausted. Mexican importations amounted to about 250 flasks in February of this year. While unrestricted competition with Mexican and Spanish mercury would make the continuance of the American industry dubious, material importations from Mexico are contingent upon stabilization of their uncertain internal affairs, while shipping capacity is still so largely engaged in post-war activities that large quantities of European metal may not arrive for some months.

As noted in our issue for Sept. 1, 1918 (p. 240), about one-third the American production and consumption is absorbed in drugs, chemicals and dental amalgams. An equal part was expected to be used by the ordnance departments for fulminate—$Hg(CNO)_2$—in detonating high explosives. Owing to the high cost and scarcity of mercury and the tremendously expanded use of fulminate, many efforts were made to substitute other compounds in whole or in part. This was only partially successful, however, owing somewhat to the uncertainty of action of the substitutes, and their high cost. In other words, during 1918 a prominent detonator manufacturer stated that straight fulminate from $100 mercury was probably cheaper than the then available substitutes. Fulminate is often combined with other substances, particularly with an abrasive, such as powdered glass, to increase its sensitiveness, and with compounds or mixtures that themselves have the property of detonating, such as sulphide of antimony and chlorate of potassium. Recently a large part of the mercury fulminate in detonators has been replaced by picric acid, trinitrotoluene, or tetranitromethylamine, according to Walter Arthur, whereby a much stronger initial effect is obtained and one part of mercury fulminate is made to detonate a charge that would have required six times as much fulminate used alone. Other substances have been found also which seem likely to replace mercury fulminate entirely for certain uses. One of these is lead azide, a salt of hydronitric acid. Large dry crystals of this salt are so sensitive as to explode when brushed with a feather, but smaller crystals are less sensitive. Other proposed substitutes are lead styphnate, $PbC_6(NO_2)_2O_2$; hexamethylamine triperoxidediamine, $N(CH_2O.OH_2)_3N$, said to be four or five times as strong as mercury fulminate; nitrogen tetrasulphide, N_2S_4; diazobenzolnitrate, $C_6H_5N_2(NO_3)$; basic mercury nitromethane; and perchlorate of trimercuraldehyde.

Minerals Relief Commission

The organization of the commission for the settlement of the net losses sustained by the producers of manganese, chromium, pyrite and tungsten has been completed. The members of the commission are John F. Shafroth, Chairman; M. D. Foster and Philip N. Moore. The commission's headquarters is Room 2131, Interior Department Building, Washington, D. C. Under the procedure established by the commission a questionnaire is sent out to the claimant, and when this questionnaire is returned, the facts which it presents form the basis for determining what further examination of the claim is warranted. The verification of facts and the field examination of mines is being carried out by the Bureau of Mines, when such examination is requested by the commission, but the commission has entire authority in making awards.

Vancouver Conference

A well-attended conference of Western mining men was held in Vancouver, B. C., during March, at which some interesting discussions were held. At the end all the members were urged to lend their efforts toward the initiation and support of a modest iron and steel industry near the international boundary, Prof. Stansfield having reported the venture as metallurgically feasible, and Minister of Mines Sloan having declared that British Columbia possessed the ore in proper quantity and quality.

A resolution interesting to metallurgists was adopted, calling for the abolishment of the fixed price for silver. From the producer's standpoint, fixed prices sometimes appear good and sometimes bad—American farmers, for instance, do not seem to resent the fixed price for wheat. On the other hand, most of the men present at the Vancouver conference were sure that in a free market the price of silver would advance to at least $1.20 per oz., due to the demands for coinage to replace the metal hoarded by subjects of Eastern governments which are in various stages of instability.

Sydney Norman, Editor of *Northwest Mining Truth*, in a plea for government control of smelters, called attention to the absence of cordial relations between

smelters and miners which appears everywhere, and which has been subject of comment for years. The smelters contend that their rates are as low as good business will permit, while the miners feel they are not getting a fair share of the returns. The speaker argued that if the rates really are correct, the smelters should not object to an impartial regulation, especially since it would remove that popular discontent and distrust which leads to a demand for outright government ownership. He also declared that in return for such regulation the British Columbian government would be justified in subsidizing the operation of a tide-water smelter and refinery to such an extent as would be necessary to insure a good volume of ore supply.

Copper Production and Price

An editorial in CHEMICAL & METALLURGICAL ENGINEERING for Feb. 15, 1919, noted the fact that wages in copper mines, mills and smelters were generally reduced on Feb. 1, to correspond approximately with the declining metal market. A number of minor labor disturbances followed, which were fortunately of short duration—even a well-advertised I. W. W. demonstration in Butte being only a flash in the pan. The steadier heads among copper operatives realized that this is only another trough in the fluctuations in the copper world, and have learned to accept, with considerable equanimity, these recurrences of slack times.

The present rate of production is rather hard to estimate. Ten large properties in February hoisted 65 per cent of their output for the preceding October. These companies have accumulated a considerable cash reserve and are able to finance a large unsold stock, while their costs, when sheared of such items as depreciation and depletion allowed on income tax returns, are still at or below the present market price.

Many smaller producers, whose aggregate output is very considerable, are not so well circumstanced, however, and have shut down entirely, or are merely holding a skeleton crew on repairs and development.

Supposing the total U. S. smelter production at the present writing to be but 50 per cent that of the 1918 rate, it would amount to 955,000,000 lb. per year, which is still equal to 83 per cent of the production of 1914 (a rather slack year). Bearing in mind the accumulated stocks of copper on hand of over a billion pounds which must be absorbed, the dislocation of industry and its impaired buying power, and the present greatly reduced export demand, it is apparent that courageous convictions as to the near future must be held by the leaders of the copper industry.

In view of the "buy now—never mind the price" propaganda of American industries in general, it is refreshing to view the old-fashioned methods used by copper men to stimulate demand. They had large quantities to sell and used the best and most reasonable method—they cut the price to a point where purchasers who needed it became interested. Buying at 14½ to 15c. was so well sustained that a moderate rise in price has since been recorded, visible stocks for sale are at least not growing, and any intending purchasers of the red metal do not need a "price guarantee." Were the inflated prices of foodstuffs, clothing, steel products, manufactured articles and other necessities of private and industrial life to approach pre-war normals with as little disturbance to labor rates as have the copper quotations, industrial activity and expansion would have its biggest obstacle removed.

Symposium on Pyrometry at Fall Meeting of A. I. M. E.

ONE of the features of the meeting of the American Institute of Mining and Metallurgiacl Engineering to be held in Chicago next September is a symposium on pyrometry which is being prepared by a special committee of which Paul D. Foote, Bureau of Standards, Washington, D. C., is secretary. Thus far 20 papers have been promised. The program of the symposium will have the following scope:

I. Methods of pyrometry.
  1. Thermo-electric pyrometry.
  2. Resistance thermometry.
  3. Optical and radiation pyrometry.
  4. Seger cones and veritas firing rings, etc.
  5. Standardization and testing of pyrometers.
  6. Recording pyrometry.
  7. Automatic, semi-automatic and manual signal and temperature control.

II. Industrial pyrometry.
  1. Pyrometry in the metallurgical industries.
    (a) Pyrometry and steel manufacture.
    (b) Heat treatment and forging of steel.
    (c) Pyrometry in the non-ferrous foundry.
    (d) Pyrometry and industrial heating furnaces.
  2. Pyrometry in the chemical industries.
  3. Pyrometry in the ceramic industries.
    (a) Pyrometer porcelains and refractories.
  4. Pyrometry and glass manufacture.
    (a) Plate glass.
    (b) Bottle glass and general chemical glassware.
    (c) Optical glass.
  5. Pyrometry and gas manufacture.
  6. Pyrometry and coke manufacture.

III. Pyrometry and its relation to science.
  1. High temperature scale.
  2. Melting points of metals and refractories.
  3. Precision optical pyrometry.
  4. Optical pyrometry and illuminating engineering.
  5. Fundamental constants of pyrometry.
  6. The teaching of pyrometry in our technical schools.

Use for Surplus TNT

All surplus TNT and other explosives owned by the War Department which can be used in clearing land, building roads, general construction work or in any way as a substitute for the ordinary commercial dynamite have been turned over to the Department of Interior. These explosives will be used on public works, and a portion may be used for the clearing of lands for honorably discharged soldiers, provided a soldiers' settlement bill is passed by the next Congress. This material, which at one time was considered practically worthless, now has an estimated value of $15,000,000. There will be no public sale of explosives by the Army, and if any surplus of this material is found in the future, it is thought that it can be used by the Department of Interior.

Imports of Tungsten-Bearing Ore

The Division of Statistics, Bureau of Foreign and Domestic Commerce, of the United States Department of Commerce reports the following imports of tungsten-bearing ore and exports of tungsten and ferro-tungsten metal for February, 1919:

IMPORTS OF TUNGSTEN-BEARING ORE, BY COUNTRIES, AND EXPORTS OF TUNGSTEN AND FERRO-TUNGSTEN METAL, BY COUNTRIES

	Imports			Imports	
Countries	Tons	Value	Countries	Tons	Value
Panama	0	$172	Japan	451	$645,886
Bolivia	14	9,984			
Chile	63	88,080	Total	1,535	$1,810,864
Peru	60	62,752			
China	424	442,626		Exports	
Chosen	46	58,375	Countries	Pounds	Value
Hongkong	477	502,989	Canada	30	$137

Import License Proposed

SPEAKING before the National Cotton Manufacturers' Association on April 25, Francis P. Garvan, Alien Property Custodian, declaring that it is necessary that Congress adopt an import license system, said:

"The Chemical Foundation proposes to place all possible information on our situation before Congress, and ask the passage of a law establishing a license system governing all chemical importations for a period of ten years. It is intended that this license system shall act at one and the same time as a guarantee to you and all other dependent industries proper importations to enable you to meet the competition of other lands, and to protect and guard our growing chemical independence. In this we ask no more than England, France, Italy and Japan already have decided to grant on behalf of their own independence. This request we base upon the following grounds:

1. Fairness to the $500,000,000 invested by loyal Americans in the hour of our need.
2. Independence and freedom of the textile, leather, paper, paint and varnish, pharmaceutical $3,000,000,000 essential American business.
3. The necessity of our national defense.
4. The destruction and prevention of the German system of propaganda and espionage in our land.
5. The advancement of pure science and research.
6. The advancement of medical science.

"The granting of this license system is not a question of conflicting economic schools. It is the question of our national independence, safety and education.

"Once we are assured time in which to work out our salvation we hope to turn to our dearest objective. Already we have started to make a survey of our laboratory equipment—governmental, university and factory. Already company after company has passed resolutions through their boards of directors placing at the disposal of our trustees, under such terms and conditions as those trustees may dictate, their entire research capacity. Government laboratories and university laboratories also have been assured us. Gentlemen, we know that offer will be unanimous.

"We soon will be able to go to the medical profession of America and offer to them the entire capacity of the country for experiment and research for the betterment of mankind. One medical chemist in one dye factory in Germany discovered the cure for syphilis, the deadliest enemy of mankind. The same medical chemist, in the same dye factory, discovered the cure for the sleeping sickness of Africa which made a continent habitable. What can we not hope for when the American medical profession is given unbounded scope and opportunity?

"We are assured that somewhere within that realm lies the hope of the cure for consumption, cancer and many of the seizures which rob us of our little ones. Can it be that herein lies the opportunity of converting the forces which up to now have been directed only toward desolation and destruction into the channels of alleviation and helpfulness to humanity? Can it be that through this medium idealist America may snatch the torch of misapplied science from the barbarian, and place it in the hands of an enlightened civilization?

"Gentlemen, Drs. Albert and Bernstorff reported to their government that America never could establish the dye and pharmaceutical industry in this country, as we lacked the moral power for the creation of such an industry, that here each party pursued its own selfish interests, but nobody kept the whole in mind; that this problem could be solved only through regard for all points of view, and that the conflicting selfishness of this country rendered that solution impossible.

"The Chemical Foundation answers this statement with a challenge, and if it can become only the co-ordinating forum for American patriotism, American sacrifice and American ability, it awaits the issue with serenity."

Merck Stock to Be Auctioned

There will be a sale of 8,000 shares of the capital stock of Merck & Co., drug and chemical manufacturers, to the highest bidder at public auction at 11 a. m., Friday, May 9, when the shares in question will be offered by the Alien Property Custodian, Francis P. Garvan, who has possession of them by virtue of their having been delivered to him voluntarily by Mr. Merck in order that the question of their ultimate ownership might be settled. The shares represent 80 per cent of the total authorized and outstanding issue of 10,000 shares of capital stock having a par value of $100 each.

The company has its principal administrative offices at 45 Park place, New York City, where the bids will be received by Mr. Joseph F. Guffey, Director of Sales, A. P. C. office, and branch offices at St. Louis, Mo., and Montreal, Canada. Its principal plant is at Rahway, N. J., where 150 acres of land are occupied by the various buildings, the total area under roof being placed at 20 acres. This plant has been greatly enlarged since 1914. The company also has a small plant at Midland, Mich., within the Dow Works.

The New Jersey Chemical Society Spring Meeting

The New Jersey Chemical Society will hold its Spring invitation meeting in the Chemical Building, Rutgers College, New Brunswick, N. J., Saturday, May 10, 1919. Dinner will be served in the University dining hall at 7 p.m.

The program for the evening includes: "Address of Welcome," by Dr. W. H. S. Demarest, president of Rutgers College; "Stability of Automobile Engine Oils," by J. V. Meigs of Montclair, N. J.; "Oxidation and Reduction," with demonstrations, by Ernest Little, professor of chemistry; "Chemical Reactions Among the Lower Animals Causing Evolution of New Species," with stereopticon views, by Daniel R. Hodgdon, director of the Newark Technical College, Newark, N. J.

Information concerning membership and invitations for the Spring meeting in May can be obtained from Mr. H. C. Cawley, secretary, 256 Vanderpool St., Newark, N. J.

American Bureau of Welding

At a meeting of the American Bureau of Welding held on April 11, at the Engineering Societies Building, 33 West 39th St., New York, the by-laws of the bureau were adopted and the following officers elected:

Director, C. A. Adams; vice-director, H. M. Hobart; vice-director, A. S. Kinsey; treasurer, W. E. Symons; secretary, H. C. Forbes.

Regular meetings of the Bureau are to be held on the third Friday of each month.

The Bureau voted to establish a Research Committee for the purpose of carrying out the plan of co-operation in conducting investigations in welding.

A committee of 52 members has been appointed.

"Hamlet" With Hamlet Left Out

THE New York Section of the Society of Chemical Industry had a meeting of unusual interest on April 18, by making the most of what threatened to be a disappointment. The paper for the evening was announced as by two authors of eminent authority whose names are well known as a guaranty of scholarship and sound practice. Preceding the paper was the presentation of two portraits to the Chemists' Club in the hall of which the meeting was held. In the absence of Major Charles E. Sholes, the honorary chairman, Dr. Parker C. McIlhiney presided, and after a short delay the meeting began. The delay was caused by the absence of both the authors of the paper of the evening, whose arrival was expected every minute. After the usual preliminaries Dr. McIlhiney called upon Dr. W. H. Nichols, president of the American Chemical Society, to make the presentation on behalf of the General Chemical Co. and the Nichols Copper Co. of the portrait of Mr. J. B. Francis Herreshoff, who received the first Perkin Medal eleven years ago.[1] He told of his start fifty years ago in the chemical business, making 66 deg. B. sulphuric acid at Laurel Hill, of his partner Mr. Walter, and their one hired man who constituted the proletariat.

At this time the petroleum refiners began to use large quantities of 66 deg. acid for the clarification of oil. It was due to the ability of Dr. Nichols' works to make dependable delivery at this concentration and not just approach the neighborhood of 65 deg. or thereabouts that the first great acid market—that of the ever growing American petroleum industry—was secured for the coming General Chemical Co. An important commercial feature, which was first observed by Mr. Herreshoff, was that acid which had been concentrated to 66 deg. could be shipped in steel drums or tank cars.

Up to his untimely death at sea while en route to Germany, Mr. Walter had been the business man, and Mr. Nichols the scientist. It now became Mr. Nichols' province to attend to the firm's business affairs, and when young Herreshoff, who, though a sophomore, had been teaching seniors chemistry at Brown University, applied for a position, he took him on. They were all young except the hired man and the competitors, and of the latter a number of kindly elder men cautioned young manager Nichols against the danger of taking such a theorist, fresh from teaching in a college, into his factory. He would surely live to rue the day, they said. Dr. Nichols confessed to a certain measure of stubbornness in the matter, with the result that the same theorist and he have been working together ever since. At this point he admitted that he was talking against time, in the hope of seeing the appearance of one of the authors of the paper on the program; but neither arrived.

Then followed reminiscences in connection with making sulphuric acid and another enterprise that was also certain, according to the advice of practical men, to end in ruin. This was no less than the purchase of a copper mine with sulphur-bearing ore which nobody else wanted. When Herreshoff had mastered the roasting problem, they thought they had a good thing, and saw no reason why they might not turn an honest penny by royalties; but again they were scorned for their youth and inexperience in the metallurgical methods of the day by the old timers both here and abroad. Then followed intimate details of technical problems and business turns, as romantic as any knights' adventures; the beginning of the electrolytic refining of copper, the reason why they were driven to it in order to maintain their independence, the quick response of Herreshoff in shifting laboratory scale operations to meet plant requirements and the organization of the Nichols Copper Co., all worth a long journey to hear.

Professor Chandler followed, presenting on behalf of Mrs. Acheson a portrait of her husband, Dr. E. G. Acheson, Perkin Medalist for 1910[2], and here again was a good story. There was the beginning with Thomas A. Edison and his work on the carbon filament, and finally Dr. Acheson's independent work resulting in carborundum and artificial graphite. It was a neatly turned biography with romance in it, all presented in Dr. Chandler's happiest style.

President Hendrick on behalf of the club received with a few remarks the two portraits that had just been unveiled by the previous speakers—but it was not given to him to kill time. Owing to the provisions of the constitution and by-laws of the club and the approaching annual meeting, there was a trustees' meeting called for the same evening, and it behooved them to convene in their room to get through with certain measures of important business.

It was still, however, merely the shank of the evening, but a little after 9 o'clock; and Chairman Dr. McIlhiney had his audience, but nobody to present a leading paper. So he called on Dr. Herreshoff, who reviewed in an intimate and informal manner many of the vicissitudes which he had met along the way, and after he had finished Dr. Acheson, who is ordinarily as shy as a girl about talking in public, was induced to take the platform, and he told his experiences with the same freedom as his predecessors.

At seventeen years of age, Mr. Acheson decided to become a chemist. His father had a small foundry near Pittsburgh and sent samples of coke and iron there to the laboratory of Otto Wood for analysis more or less regularly. Feeling that a very practical way to get a chemical education would be through Wood, young Acheson went to Pittsburgh filled with great hopes for his future. To his surprise, Wood's advice was "Don't become a chemist. It's a humdrum life with no prospects, etc." Undoubtedly it is fortunate for so keen a mind as that possessed by our inventor of electrothermal products of the carbosilicon series that he drifted around until he landed in Mr. Edison's keeping at Menlo Park. The subsequent events[3] are too well known to our readers to be described here in detail. Mr. Acheson mentioned his present research on colloidal deflocculation with graphite and clay. He has been able to produce perfectly translucent solutions of these materials, which are so finely divided that they have excited the admiration of the foremost ultramicroscope investigators.

It was just as though those present had been sitting in the club about a cosy fire, while W. H. Nichols, J. B. F. Herreshoff and E. G. Acheson had each opened up, and told, as among friends, his experiences in applied chemistry, with a delightful little talk by the fine old dean of American chemists added to it. It was a memorable occasion.

Metallic Coatings for Rust-Proofing Iron and Steel—I

A Concise Account of the Nature of Corrosion, Rust-Proofing Metal Coatings, With Recommendations, Is Given—Description and Comparative Values of Different Methods of Testing Coatings, Especially of Zinc

By HENRY S. RAWDON,[1] M. A. GROSSMAN[2] and A. N. FINN[3]

THE study of the deterioration of iron and steel, particularly by corrosion, and the means for mitigating the same, has probably received more attention, and properly so, than any other phase in the study of steel. In the following article, the experimental results, when given, have been taken from the results of the numerous examinations and tests of materials submitted to the Bureau of Standards during the past few years. The general and more descriptive portions have been summarized after a careful review of the most helpful articles in the literature on the subject of corrosion, which is extremely voluminous.

I. Introduction

1. General Nature of Corrosion

Various theories have been advanced concerning the nature of the process of the corrosion of iron, and a vast amount of experimental work has been done to support these theories. All agree, however, that the process is electrolytic in its nature, and the various hypotheses differ only as to the factors by which the electrolytic action is brought about. Iron and steel will not corrode in dry air—the presence of moisture is an essential condition, and according to one of the theories, carbon dioxide must also be present. Protection from atmospheric corrosion may be afforded in two ways; first, by mechanically excluding all moisture and other corroding agents from the iron and steel, and, second, by using coatings of such a chemical nature that the covering itself is corroded in preference to the iron or steel beneath. It must be remembered that all "rust-proofing processes" are temporary only in character; some, however, are so far superior to others that the use of the term "rust-proofed" is justifiable in such cases.

The attempt to prolong the life of iron and steel parts in service by protecting them against corrosion has led to the adoption of many materials and processes for coating. The protective materials fall in general into three classes: (1) The metallic coatings, (2) the coatings in which the iron to be protected is itself converted at the surface into some less corrodible compound, and (3) the organic coatings, including paints, varnishes, enamels, etc. The metallic coatings include all the common metals and alloys that can be applied at all readily to steel, namely, zinc and aluminium, which are electro-positive to iron (as explained below), and tin, lead, "terne" and other lead alloys, copper, nickel, cobalt, brass, bronze and silver, all of which are electro-negative to iron. In the case of the iron compounds, the iron at the surface is converted to oxide or to some other compound and the piece is then usually given an oil finish. The organic coatings will not be discussed in this article.

2. Principles Underlying Methods of Prevention

Of the metallic coatings, the best, by far, for general rust-proofing is zinc. The principal reason for this lies in the chemical nature of zinc—it is the only one of the commonly used metals that is electro-positive to iron, that is, it has a greater tendency to be oxidized than has iron. In the following table the metallic elements are arranged in their proper order in the potential series. Any element is electro-positive to any element following and electro-negative to any element preceding it in the table:

POTENTIAL SERIES

K	Potassium	Fe	Iron	Cu	Copper
Na	Sodium	Cd	Cadmium	As	Arsenic
Ba	Barium	Tl	Thallium	Bi	Bismuth
Sr	Strontium	Co	Cobalt	Sb	Antimony
Ca	Calcium	Ni	Nickel	Hg	Mercury
Mg	Magnesium	Sn	Tin	Ag	Silver
Al	Aluminum	Pb	Lead	Pt	Platinum
Mn	Manganese	H	Hydrogen	Au	Gold
Zn	Zinc				

When any steel article with a metallic coating is scratched or abraded so that a small area of the steel is exposed, the two dissimalar metals together with a small amount of moisture derived from the atmosphere will form a tiny galvanic cell, set up a current and start corrosion. That metal which is electro-positive to the other will be the one to be oxidized, while the electro-negative metal will remain uncorroded. So if the coating metal is zinc, it is zinc that will be oxidized, while the iron remains bright and uncorroded until the "bare" spot becomes so large that the central portion is beyond the "protective zone" of the surrounding zinc. On the other hand, should the coating happen to be tin, which is electro-negative to iron, it would be the steel that would suffer. In such a case, the tin coating is actually injurious, because without it the steel would oxidize at the normal rate, with no galvanic action to hasten the corrosion. The value of tin for coatings depends upon other factors than its electrochemical nature.

Zinc, then, has the advantage of being electro-positive to iron and so preventing its corrosion, especially on small exposed areas such as "pin-holes" in the coating, scratches, etc. One other common metal, aluminium, is also electro-positive to iron, but does not share the other advantages enjoyed by zinc, such as relatively low cost, the ease with which it can be applied to steel in quite a number of ways, and the fact that with a little care it will solder readily. (Refs. 1-11 inc.)

II. Types of Coatings and Methods of Application

1. Metallic Coatings

a. Zinc. The oldest process for zincing or galvanizing, and the one most widely used, is the hot-dipping process, in which the steel, after a preliminary cleaning

[1]Asso. Physicist (Metallography), Bur. of Standards.
[2]Metallographist, Vanadium Co. of America.
[3]Asso. Chemist, Bur. of Standards.

of the surface, is immersed in molten zinc, left in the bath long enough for the steel to reach the temperature of the zinc and then withdrawn with the coating of zinc adhering to it (24, 25, 26, 27). It is a simple process and gives excellent results on smooth surfaces. In general, a piece of steel that has been zinc-coated by the proper hot-dipping method will be well protected against corrosion even under severe conditions of exposure.

Sherardizing

Another method of zincing, called sherardizing, consists in heating the steel in a so-called "zinc vapor" atmosphere. The steel parts are packed in a revolving drum with zinc dust containing a small amount of zinc oxide, and heated at 350 to 375 deg. C. (28, 29, 30, 31, 32, 33, 34). The cylinder is made to rotate slowly on its axis to tumble the parts and insure evenness of coating. Usually 3½ to 4 hours' heating is required to produce a satisfactory coating.

Zinc is also applied to steel by plating from an aqueous solution (36, 37, 38, 39, 40). Those commonly used are either a solution of zinc sulphate containing a small amount of free acid or a solution of zinc cyanide or one of zinc oxide in a mixture of sodium cyanide and sodium hydroxide. The plating usually takes from a half-hour to an hour, but may be continued longer to produce very heavy deposits.

There are other methods of applying zinc which are used less often. The Schoop spray gun, for example, is a device for spraying molten metal upon an article to be coated (41, 42, 43, 44). The zinc, in the form of wire, is fed into the spray gun, where an oxy-acetylene flame melts it, and a strong current of air projects it from the nozzle in the form of a very fine spray, which is directed against the steel. In another process, called "epicassit," the zinc, in the form of filings, is mixed with a flux, made into a paste and then painted on the steel (45). The article is then heated until the zinc just melts, making a continuous adherent coating.

Advantages and Disadvantages of Each Type

Of the three forms of "zincing" most commonly used, namely, hot-dipping, sherardizing and electroplating, each type has its advantages and its disadvantages. Hot-dipping is excellent for even surfaces, as it gives a heavy coating in a very short time. The thickness of coating on such material as sheets and wires can be easily regulated by "wiping" and other mechanical devices; on irregular shaped articles, however, there is no simple way of regulating the amount of zinc used. This method cannot be used on accurately machined parts, such as screw threads, for obviously the zinc would collect in sharp corners and alter the original outlines of the piece. Neither can it be used on a highly hardened steel where the heating to 450 deg. C. (the approximate temperature of the zinc bath) would soften the steel too much for its intended use.

Sherardizing has the advantage of giving very even coatings. The coating on a screw thread, for example, will show no appreciable variation from the top to the root of the thread. On the other hand, sherardizing is a slower process, and it cannot be used on such hardened steels as would be softened too much by heating at 375 deg. C. for 3 to 4 hours. Neither is the method suited to handling large sheets, etc. Furthermore, the quality of coating produced by this method is greatly modified by the conditions of operation, such as purity of the zinc dust, uniformity of heating, duration of treatment, so that widely different results are obtained in practice.

Electroplating has the advantage of being readily applied to small and delicate articles that are not easily handled in other ways, and the obvious advantage that it can be applied to steel without modifying any previous heat treatment. One advantage of this process is the ease of operation; there are several devices now upon the market by means of which the operation (including the preliminary cleaning and final washing) can be made a continuous one requiring but little supervision. Another distinct advantage of electroplating is the ease of control of the thickness of the deposit—within rather wide limits this is directly proportional to the period of deposition. On parts having sharp corners or depressions, however, it is apt to give uneven coatings. On threads, for example, there will be an accumulation of zinc at the top of the thread, while the root may be nearly bare, and even on flat plates it has been found that the coating is heavier at the edges than in the center. It seems probable, however, from some recent work done by this Bureau, that such differences are much less pronounced in zinc deposited from the cyanide solution than in that from the sulphate bath.

b. Aluminium. Aluminium has never been used commercially on a large scale for rust-proofing, on account of the difficulty of applying it to steel. Aluminium is electro-positive to iron, and would, therefore, make a good protective coating. One method of applying it, called "calorizing" (46, 47), is somewhat similar to sherardizing, in that the steel is packed in a mixture containing powdered aluminium and heated at 900 to 950 deg. C. This process is used commercially to a limited extent.

2. Soft, Fusible Metals (Tin, Lead and Their Alloys)

Almost all of the metallic coatings other than zinc and aluminium divide naturally into two chasses, the soft low-melting-point ones and the hard metals with relatively high fusion points. Those in the easily fusible class, such as tin, lead and their alloys, are applied almost altogether by hot-dipping. Those not so readily fused, such as copper, nickel, cobalt, silver, brass, etc., are for the most part electroplated.

One of the most widely used of the coating metals is tin. It is in the class of metals that are electro-negative to iron, so that a tin coating must be free of pin-holes and must not be abraded or injured, or accelerated corrosion will set in where the steel base is exposed. However, the tin itself corrodes very slowly, and it has several advantages in that it is applied very easily by hot-dipping, is soldered more readily than any other coating and has the further very important advantage of having no toxic effect, so that it can be used in food-containers. Hot-dipping is used for the large majority of tinned articles, but the metal may also be applied by the Schoop spray and by plating (51, 52, 53).

Lead alloys are applied by quite the same processes as is tin, but they lack some of the advantages of tin. Lead does not solder so readily because it oxidizes quickly when heated, but it is much cheaper than tin, and has been used especially in terne, which is an alloy of about ¾ lead and ¼ tin. The electrodeposition of

lead for the production of protective coatings has recently come into commercial use. Lead, however, is electro-negative to iron and has the corresponding defects (54).

3. Hard Metals (Copper, Nickel, Cobalt and Brass)

Copper has been used a great deal for rust-proofing. Metallic copper itself corrodes very slowly, and it has found such wide application largely because it is applied very readily by electroplating. But it is electro-negative to iron, so the coating must be well applied and be free of bare spots and pin-holes to protect completely against corrosion. A practice that is fairly common is the buffing of coppered parts to give a bright finish; this renders the coating more uniform in thickness and covers up such imperfections as pin-holes, etc. If the coating as deposited is very thin, however, severe buffing will remove it almost entirely in places and so accelerate corrosion.

In addition to electroplating, copper is applied with the Schoop spray gun, and by the so-called "copper-clad" process (49, 50). In the latter, copper is cast around a steel billet, and the billet rolled down to rod or sheet form. Copper so applied is less likely to be porous than is the case with electroplated or sprayed metal. The process of depositing zinc-coatings designated as "epicassit" has been modified for use in copper plating. The process is now being used industrially to a very limited extent (48).

Use of Nickel

Nickel is used for articles that are to have a light color, especially if a bright polish is desired. Most nickel is applied by electroplating, but it can also be applied by a process similar to the "copper-clad" process. Nickel is another one of the elements electro-negative to iron, although, being quite close to iron in the electro-chemical scale, its injurious effect is likely to be a little less pronounced.

Cobalt is quite similar to nickel in its properties, and is used in much the same way.

The electrodeposition of brass upon steel can be carried out with success and is used extensively on small articles such as builders' hardware, lighting fixtures, etc. It is plated from a solution containing both copper and zinc. It has no peculiar advantages as regards rust-proofing, but the brass color is sometimes desired. Brass has also been applied as in copper-clad and nickel-clad products, as has also bronze.

4. Oxides and Salts of Iron

a. Oxides. The oxide coatings on iron and steel are in general prepared by heating the metal in a suitable atmosphere or by oxidizing in the presence of certain aqueous or fused chemical reagents. Repeated alternate heatings in oxidizing and reducing gases give a comparatively heavy coating of black iron oxide, considered to be FeO. The etching and "coloring" processes (55) give thinner coatings, usually of a lower order of resistance to corrosion. The oxide coatings are always oiled, and undoubtedly owe some of their rust-resistance to this fact (56).

(1) *Bower-Barff Type.* The original Bower-Barff method consisted in heating the steel at 350 deg. C. and above, in air or sometimes in the presence of superheated steam; when a coating of ferric oxide had been formed, hydrocarbons were introduced which served to reduce the ferric oxide, Fe_2O_3, to ferroso-ferric oxide, Fe_3O_4. This process and the variations of it give a coating which offers a very fair degree of resistance to corrosion. One modern variation which is used extensively consists in heating at a low red heat in a mixture of steam and benzine. The modifications of the Bower-Barff process are known under quite a number of names, e.g., the Swann, the Bontempi (58), the Gesner, the Weigelin, etc.

(2) *Heating With Oil, etc.* In this type of process, the steel is heated in volatilized oil or in a thick, smoky atmosphere, whereby a deep black oxide coating is produced. The Carbonia process is typical, in which the steel is heated at about 220 deg. C. in a mixture of burnt bone and oil. In other processes the steel is heated in burnt bone and charcoal, or in oil and sawdust. The steel may also be oiled first and then heated to a temperature ranging from 300 to 550 deg. C. The process of "blacking" in a forge is similar: the steel is cleaned of loosely adherent scale and then held while quite hot in the thick smoky flame from the forge.

(3) *Etching ("Browning," "Bluing," etc.).* Solutions of chemical reagents are applied to the steel with a cloth or sponge, the steel is allowed to oxidize for some hours while drying; the rust is then scraped off, leaving a thin adherent coat of oxide. The process is repeated a number of times, depending on the depth of color desired. The surface is then oiled. The following is a representative list of combinations of reagents that have been used for producing the respective colors:

	(Pts. by Wt.)
BLACK	
Bismuth chloride	20
Mercuric chloride	40
Copper chloride	20
Hydrochloric acid	120
Alcohol	100
Water	1,000
Copper nitrate solution (10 per cent)	700
Alcohol	300
Mercuric chloride	50
Ammonium chloride	50
Water	1,000
BROWN	
Alcohol	45
Iron chloride solution	45
Mercuric chloride	45
Sweet spirits of niter (ethyl nitrite + alcohol)	45
Copper sulphate	30
Nitric acid	22
Water	1,000
Nitric acid	70
Alcohol	140
Copper sulphate	280
Iron filings	10
Water	1,000
BLUE	
Iron chloride	400
Antimony chloride	400
Gallic acid	200
Water	1,000
BRONZE	
Manganese nitrate solution (10 per cent)	700
Alcohol	300

(4) *Niter Bath.* The cleaned steel is heated in fused sodium nitrate or potassium nitrate, or a mixture of the two, often with the addition of manganese dioxide. The color acquired by the steel depends on the temperature of the bath as well as its composition. Other fused oxidizing baths can probably be used also.

(5) *Temper Colors.* The "temper colors" seen on steel when it is tempered between 220 and 320 deg. C. are due to a thin layer of oxide. Such a layer of oxide is often applied as a protecting layer, the blue color being the one usually used. The steel is heated in free

air, and the various colors will be produced at the following temperatures:

	Deg. C.	Deg. F.
Pale yellow	220	418
Straw	230	446
Brown	255	491
Purple	280	536
Pale blue	300	572
Dark blue	315	599

The color depends somewhat on the duration of the heating and to a lesser extent on the nature of the steel.

(6) *Hot Oxidizing Solutions.* Boiling alkaline oxidizing solutions have been used, such as boiling sodium hydroxide solution, containing sodium picrate (Guerini process), sodium nitrate, sodium peroxide, etc. It seems probable that many oxidizing solutions would be found suitable. The nature of the steel affects the structure of the coating produced.

(7) *Miscellaneous.* Other processes for producing black coatings include the following: Immersion in boiling solution of lead acetate and sodium hyposulphite; making the iron the anode in an electrolytic cell, the oxygen from the decomposition of the water giving a coating of oxide; dipping in 10 per cent potassium bichromate solution, followed by heating in a smoky flame; copper plating by dipping in copper sulphate solution, followed by immersion in a solution of sodium hyposulphite and hydrochloric acid. A brown color may be produced by heating in steam with acid vapor for a few hours. A type of coating termed "black nickel" is used rather extensively. This is electrolytically deposited, but the commercial practice varies widely as to the composition of the bath used and hence also the coating. The deposit made from the sulpho-cyanate bath is most uniform in its composition and properties and is to be preferred, particularly if the article has received a preliminary coating of zinc.

b. Salts. In a coating of this type of rather wide commercial application, the iron at the surface is converted into a salt by immersing the steel in hot dilute phosphoric acid, sometimes containing manganese dioxide, soluble chromates, or other metallic salts. After the proper length of immersion, the steel is withdrawn and dried. The color is then grayish-white, but becomes black when oiled. This is called the Parker (57) or the Coslett process (59). Its resistance to corrosion is of the order of the light oxide coatings.

III. Methods of Testing Coatings

1. Description of Methods

Considerable difference of opinion has been expressed concerning the relative merits of the different types of the protective coatings, and various tests have been suggested to show the virtues of a particular coating. The basis on which some comparative tests are made is incorrect; for instance, the comparative values of lead, tin, or terne plate and zinc cannot be determined by treatment with sulphuric acid or ammonium chloride solutions, as is sometimes suggested; the Preece test should not be applied to sherardized coatings, and results obtained by this test on hot-dipped or plated coatings are not comparable. If the Preece test is made on the same type of material, by the same operator, under exactly the same conditions of time, temperature, concentration of solution, etc., comparable results may be obtained. There is no universal test that can be applied to the different kinds of protective coatings; each type must be considered alone and the limitations of each must be taken into account.

The usual methods for testing zinc coatings are the Preece test (24), the hydrochloric acid-antimony chloride method (68), the basic lead acetate method (71), and the salt spray test (69), which recently has been receiving considerable attention. In addition to these purely chemical methods, metallographic measurements are also made of cross-sections of the coating of the material under consideration.

a. Stripping Tests. The Preece test is made by dipping, for a period of one minute each, the carefully cleaned sample in a solution of copper sulphate. The sample is washed in running water and lightly rubbed with clean waste between dips, and the appearance of bright adherent copper indicates the end of the test. The solution is prepared by dissolving 36 parts of commercial copper sulphate crystals in 100 parts of water and then adding some cupric oxide to neutralize any free acid. This solution is diluted with water until its specific gravity is 1.186 at 18 deg. C., and it should be used at approximately the same temperature.

Hydrochloric Acid-Antimony Chloride Method

The hydrochloric acid-antimony chloride method for determining amount of coating on galvanized metal is as follows:

A sufficient number of specimens should be used in each test to have an area of not less than 25 sq.cm. (4 sq.in.). They are weighed (to the nearest milligram) and then dipped in 100 cc. (or more if necessary to cover the specimens) of concentrated hydrochloric acid (specific gravity 1.20), to each 100 cc. of which has been added 5 cc. of a solution made by dissolving 20 g. of antimony trioxide in 1000 cc. of concentrated hydrochloric acid. The same portion of hydrochloric acid may be used repeatedly up to five times, by adding before each immersion an additional 5 cc. of the antimony chloride solution. The samples are immersed in the solution for one minute. They are then washed and scrubbed in running water to remove the deposited antimony, and are dried and reweighed. The loss in weight represents the weight of the zinc coating, which is calculated directly to grams per $dm.^2$; or to ounces per sq.ft. by multiplying the $g/dm.^2$ by 0.328 (or for practical purposes, by dividing by 3). Often it may be most convenient, on irregular shaped parts, to express the weight in grams (or milligrams) per piece, thereby avoiding uncertainty due to the area of a sample.

Basic Lead Acetate Method

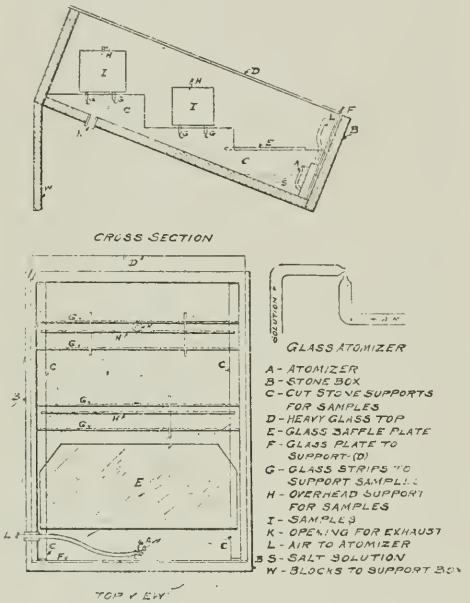
The basic lead acetate method is carried out essentially as follows:

The solution is prepared by dissolving 400 g. of crystallized lead acetate in 1 liter of water, to which is then added 4 g. of powdered litharge. After shaking, the solution is decanted or filtered and is diluted until the specific gravity is 1.275 at 15.5 deg. C. The weighed test specimens are immersed in a sufficient amount of this solution to cover them, and at the end of three minutes are removed and freed from adhering lead by rubbing or brushing lightly. They are again immersed for successive three-minute periods (usually four periods are sufficient) until a bright iron surface is exposed. The specimens are then cleaned, dried and reweighed, the loss in weight representing the weight of the zinc coating.

b. Salt Spray. The operation of the salt spray test has received considerable attention at the Bureau of Standards during the last two years, and although all types of protective coating have been tested, special attention was given to zinc coatings.

The test as conducted at the Bureau of Standards is made in an Alberene stone box, with a glass cover and glass supports for the samples. The construction is indicated in the accompanying diagram. The stone box will run down to the edge instead of dripping on the samples.

A 20 per cent solution (by weight) of commercial sodium chloride (20 g. salt and 80 cc. water, or 2 lb. salt and 1 gal. water), filtered if necessary, is used, and



SALT-SPRAY BOX FOR ACCELERATED CORROSION

with an air pressure of about 6 or 7 lb. per sq.in. a very fine mist is produced.

The compressed air is passed through a glass-wool or cotton plug and then through water to remove oil and dust, and to saturate the air with water vapor, which prevents concentration of the salt solution and crystallization of the salt on the tips of the atomizer. The baffle plate prevents the salt spray from blowing directly against the test pieces.

The samples, after washing with gasoline and ether to remove all grease, are placed in the spray box in a vertical position on the glass rods or strips. They are removed from the bath every twenty-four hours, washed with water, using a moderately stiff bristle brush, and after drying are carefully examined for the presence of red or yellow iron rust. The first appearance of rust indicates the conclusion of the test, but valuable information may be obtained by continuing the test and observing the extent of the corrosion produced by longer exposure.

If Alberene stone is not available, the box may be made of glass, stoneware, porcelain, waterproofed wood or any other insoluble and non-corrosive material, and all connections should be of glass or rubber.

2. Comparative Values of Different Methods

The hydrochloric acid-antimony chloride and basic lead acetate methods are "stripping tests" and give the total amount of coating on a surface; the Preece test has been used to show thin spots and also to show, in a general way, the thickness of the coating. The lead acetate method may also be used to show thin spots, but used in this way is liable to show the same irregularities that led committee A-5 of the A. S. T. M. to condemn the Preece test (75).

The comparative value of the hydrochloric acid-antimony chloride and the basic lead acetate methods for stripping are discussed in the report of committee A-5 for 1917 (75), and either is considered satisfactory for sheet metal and wire, which were the materials tested.

The hydrochloric acid-antimony chloride method has been used at the Bureau of Standards almost entirely for stripping because it removes the coating more quickly and can be applied to material of any shape and to all types of zinc coatings. The basic lead acetate method does not lend itself to irregular pieces such as bolts, nuts, screws, etc., or parts with holes in them, on account of the difficulty of removing the precipitated lead from the small depressions or holes and on account of the possible failure to react with sherardized coatings, which is also characteristic of the Preece test.

The hydrochloric acid-antimony chloride solution usually removes plated zinc completely in from five to fifteen seconds and hot-dipped zinc in less than thirty seconds, but it has often been found that sherardized zinc is not completely removed during a one-minute immersion, four immersions sometimes being required to remove all the coating.

Progressive Loss of Coating

The following results illustrate the progressive loss of coating when four pieces of sherardized sheet metal, 1 in. square, were dipped in the hydrochloric acid-antimony chloride solution for periods of one minute each.

LOSS OF WEIGHT IN GRAMS

	A	B	C	D
First dip	0.3371	0.4102	0.3966	0.8380
Second dip	0.0490	0.0158	0.0171	0.0477
Third dip	0.0017	0.0017	0.0017	0.0040
Fourth dip	0.0010	0.0008	0.0010	0.0007

The fourth value may be attributed to iron, as these figures are of the general magnitude of those obtained when bare iron is treated with the acid mixture used in stripping.

The following figures indicate that the acid method of stripping may be more accurate for electrolytic zinc than the basic lead acetate method which was shown by accurately weighing the amount of zinc deposited on some iron sheets and then stripping them:

Method of Stripping	Weight of Coating in Grams: Deposited	Stripped	Per Cent Coating Found
Lead acetate	0.2888	0.2537	88.0
	0.1694	0.1572	93.0
Hydrochloric acid-antimony chloride	0.2141	0.2157	100.7
	0.1965	0.1992	101.4

The salt spray test has been applied to a large number of samples, some of which were taken from stock at various plants, while other samples were prepared especially for this purpose. These tests were made in conjunction with stripping tests and metallographic examination. A study of the results obtained indicates that there is no close agreement between the life of a coating determined by the salt spray test, the amount of zinc determined by stripping and the thickness of the coating measured metallographically. The following

examples taken from the large number tested illustrate the differences between amount of coating determined by the two methods and the variation shown by the salt spray test.

Sample	Thickness of Coating (Inches) — Microscopic Examination of Cross Sections: Stripping	Average	Average Minimum
A (hot dipped)	0.00276	0.00303	0.00173
	0.00307	0.00646	0.00339
B (hot dipped)	0.00191	0.0028	0.00233
	0.00185	0.0046	0.00268
C (hot dipped)	0.00181	0.0039	0.00260
	0.00172	0.0029	0.00189

Salt Spray Test

Type of Coating	Thickness of Coating (by Stripping)	No. of 24-Hr. Days Required for First Appearance of Rust
Electroplated	0.00040 inch	3
Electroplated	0.00077	15
Electroplated	0.00073	9
Hot dipped	0.00109	5
Hot dipped	0.00133	6

The tests from which the above conclusions were drawn were repeated to see if more consistent results could be obtained, but no better agreement was found. It was thought these differences might be due either to the manipulation of the salt spray test, to the very irregular shapes of the test pieces, or a lack of uniformity in different samples of the same kind from the same lot. It was found on investigation that samples of plated and hot-dipped sheets and chilled-cast zinc placed in the salt spray tank in a vertical position corroded more rapidly than those in a horizontal or an inclined position. It was also found that zinc is not removed by immersion in a solution of salt nearly as rapidly as it is by a spray of the same solution, and consequently zinc in the holes or depressions in the surface of a specimen where the salt solution may collect will not be removed as rapidly as at other places. It becomes evident that although the thickness of plated zinc on recessed parts is less than on outer surfaces they may not show failure as rapidly as the outer surfaces. It was also found that the amount and distribution of zinc on different samples of sheet metal, prepared at the same time and presumably under similar conditions, varied so much that the results obtained on one of several samples could not be taken as characteristic of the set.

To Remove Basic Zinc Carbonate Coat

A hard and adherent coat of basic zinc carbonate nearly always forms on the surface of the test piece when exposed to the action of the salt spray, and efforts to remove this completely without affecting the metallic zinc have not been successful. Treatment with acids undoubtedly removes zinc, although Tambou (74) recommends a mixture of ammonium carbonate, ammonium chloride and ammonia for differentiating between zinc oxide and metallic zinc. This solution was not found satisfactory, as it attacks metallic zinc somewhat readily. A zinc plated sheet (51.7 sq.cm.) immersed for periods of 15 minutes each in a solution lost weight as follows:

First dip	6.4 mg.
Second dip	3.6 mg.
Third dip	4.1 mg.
Fourth dip	4.2 mg.

After trials of various methods to remove the basic zinc carbonate, the one finally adopted is to brush the sample daily in running water with a moderately stiff bristle brush. This was found to have practically no effect on metallic zinc, but it did not remove all the zinc salts. This layer must have some protective action, and as it is not uniformly distributed, zinc will be removed more rapidly at some places than others, producing erratic results.

The salt spray test as a measure of the relative value of zinc coating depends on the time required for the complete removal of the zinc at the thinnest point, which is usually indicated by the appearance of iron rust. It was thought that iron exposed to the action of the salt fog would show rust almost at once, but this is not always true. Numerous cases have been observed, however, in which areas of iron as large as 1 sq.cm. have been completely freed from zinc, as shown metallographically, yet no rust appeared. This is probably due somewhat to the type of iron exposed and also to the protective action of the adjacent zinc through the strong salt solution as electrolyte, for it can readily be shown that certain steels corrode more readily than others and that the "zone of protection" exerted by zinc on iron increases readily with the concentration of the salt solution. It is difficult to explain the quick appearance of iron rust on zinc-coated material in the salt spray test unless it is assumed that there is an insufficient layer of salt solution between the zinc and exposed iron to allow the zinc to exert its electropositive nature or that the basic zinc carbonate which is formed collects in such a way that it insulates the zinc from the iron and destroys its protective effect.

Salt Spray Test Regarded as Best

Although the salt spray test is subject to many objections, it may be regarded as the best test for zinc coatings that has yet been developed. It is especially useful in determining the relative value of zinc coatings for marine exposure. No definite statement can be made about the life of zinc coating in this test, but in a general way, a sample showing rust spots in less than 1 day (24 hours) should be regarded as unsatisfactory, while a life of two or three days would indicate a coating that could safely be used under moderate conditions of exposure, and a life of at least 4 to 6 days should be required for severe conditions of exposure.

Since electro-negative coatings accelerate the corrosion of iron at exposed points, continuity of coating is of more importance than the thickness of the protecting layer. Any test which will effectively show the presence, number and approximate size of breaks or pin-holes may be used to indicate in a general way the quality of the coat as applied. The salt spray test will detect "pin-holes" in a comparatively short time (usually from 3 to 10 hours) and on longer exposure give some indication of the probable life of the protective coating. But the comparative value of the various metals cannot be determined by this method alone; purpose and service conditions also must be taken into consideration.

Other Tests

Other tests which detect lack of continuity in metal coats have the advantage of speed, while their application does not spoil the part tested for subsequent use. Such tests are based upon color reactions which take place between the solution and exposed (uncoated) iron. Pin-holes in most electro-negative coatings can be detected readily by immersing the sample in a 1 per cent solution of sodium ferricyanide in 2 per cent sulphuric acid. The appearance of a blue precipitate at any point indicates a hole in the coating, or exposed

iron. This test is readily applied to the electro-negative coatings such as lead, copper, lead-tin, or lead-antimony alloys. Acetic acid may be substituted for sulphuric acid, but the action will be slower. Similar results may be obtained by exposing to the air a specimen which has been dipped first in dilute acetic acid and then in a warm solution containing 5 per cent hydrogen peroxide. Breaks in the coating are indicated by a blue precipitate.

The oxide coatings cannot be tested by any method so far developed because the iron in the coating gives the same results as the base metal itself, and their protective value depends often on the amount of oil in the coating.

The phosphate coatings are more readily tested, but in this case, too, the iron in the coating makes it difficult to draw definite conclusions. A great many tests have been made at this Bureau on samples prepared by treatment with the various phosphoric acid solutions, and it can be definitely stated that this treatment does not give satisfactory protection for steel parts that are exposed to water, salt air, moist atmosphere, or considerable friction, but it has some merit if conditions of exposure and handling are very moderate. The value of this treatment is increased if the treated surfaces can be frequently oiled, but this will not materially increase its resistance to mechanical action. The experience of this Bureau indicates that this treatment has not been successfully applied to case-hardened products without removing most, if not all, the hardened surface by sand blasting or pickling.

IV. Recommendations Concerning Coatings

1. Zinc coatings should be given preference over all others when the object of the coating is protection against corrosion only.

2. For general use on large smooth surfaces, sheets, rods, wires, pipes, etc., the hot-dipped zinc coatings are entirely satisfactory, though some of the other processes are more economical in the amount of zinc used. On articles which must be sharply bent or otherwise shaped, too heavy coatings of this hot-dipped type should not be used on account of the tendency of the coating to flake off at such points.

3. One oz. of zinc per sq.ft. of surface exposed (0.0017 in. thickness) may be considered as satisfactory for most purposes, but less may be sufficient if evenly distributed.

4. Of the different types of zinc coatings the "hot-dipped" and sherardized are not to be recommended for hardened and tempered steels (springs, etc.); the plated zinc and the sherardized coatings are both recommended for accurately machined parts; threaded portions, however, are best coated by sherardizing; the "spray" coatings are valuable for large or complex parts which must be coated *in situ* or after assembling.

5. For indoor use and to a limited extent outdoors, for parts which are so placed as to be easily inspected and which are kept well oiled, other coatings than zinc, e.g., the oxide and other black finishes, may be used. For *severe* service, zinc only should be depended upon.

6. In general, nothing is gained, from the standpoint of resistance to corrosion, by first coating an article with copper, or a similar metal, and then finishing with zinc. If a zinc coating is to have a black finish, "black nickel" may be used as a finish.

7. The use of oil and like substances on any type of coating is to be strongly recommended. The life of zinc coatings, particularly those of a porous character, may be prolonged almost indefinitely by periodically oiling them.

8. The time required for the appearance of rust on zinc coated articles when exposed to salt spray may in a general way be taken as an indication of whether the coating is satisfactory for outdoor exposure, e.g.:

24 hours ..... unsatisfactory
48 to 72 hours.....for mild exposure
96 to 144 hours.....for severe exposure

Potash From Wood Ashes

An investigation concerning the production of potash from wood ashes, conducted by the U. S. Forest Products Laboratory at Madison, Wis., disclosed the following facts:

The ash content of hardwoods ranges from 0.5 per cent to 3.02 per cent, with an average of 0.61 per cent. The ash content of the coniferæ seems to vary from 0.02 to 0.82 per cent, with an average of 0.30 per cent. There may, however, be very wide variations in the ash content of the same species, as is instanced by black walnut with a minimum ash content of 0.21 per cent, a maximum of 1.96 per cent, and an average of 0.79 per cent; or chestnut oak, whose minimum, maximum and average ash contents are respectively 0.33 per cent, 1.96 per cent and 0.77 per cent.

The potash content of pure, well-burnt ashes may be very high, ranging from 10 per cent up to 35 per cent. These figures are, however, of but little commercial value, since all commercial ashes contain impurities, such as sand, sawdust or charcoal, and these impurities may make up a very large per cent of the total ash. The potash content of commercial wood ashes may vary over a comparatively wide range, depending somewhat on the wood and the kind of furnace or stove used. The average of 111 analyses made in Connecticut from 1906 to 1915 was 3.6 per cent K_2O.

The initial cost of a potash plant of 24 leachers, including building, is between $3000 and $4000. The cost of manufacture of potash, not including the cost of the wood ashes, will vary from about 7 to 17c. a lb., depending upon the kind of ashes obtained and whether or not the plant is running at full capacity.

It is evident, therefore, that the manufacture of potash from wood ashes will not be a paying proposition when normal prices are resumed, except in those cases where the plant has already been paid for and is owned by the potash maker who makes no charge for his own labor but accepts his profit as compensation for his work. Under these conditions the cost of manufacture of potash, exclusive of the cost of ashes, may be reduced to about 5c. a pound.

War Department Disposes of Lead

Disposition of the surplus stocks of lead owned by the War Department is being made at current local market prices in the community in which the surplus is held. This surplus is scattered throughout the country, and in no one place is there a large quantity. Reports from the various bureaus show a total amount of 7000 tons of lead to be in possession of the War Department. This surplus of 7000 tons represents but a small percentage of the year's production of lead and is not sufficient in quantity to affect the market in any way. This lead is not sold in quantity at one time but in small quantities in various places.

Treatment of Cuprodescloizite for Extraction and Recovery of Vanadium, Lead and Copper

Preliminary Experiments to Determine Best Method of Preparation and Extraction of Vanadium From the Ore—Niter Cake-Sulphuric Acid Extraction Most Economical—Leaching Tables—Copper and Lead Recovered Sufficient to Pay Costs

By J. E. CONLEY*

OWING to the strong competition of the Peruvian patronite as a source of vanadium, the production of this metal from ores found in the United States has in a measure been neglected. The rumored decrease in the available supply from Peru, and the continued demand for vanadium in the steel industry, are sufficient grounds to encourage and stimulate the production of this important metal in this country.

Some vanadium is being obtained by the treatment of roscoelite and also as a by-product in the treatment of carnotite ores for radium. The treatment of ores for vanadium alone has not been extensively done and certainly warrants the attention of companies and individuals owning vanadium properties, as well as of the consumers themselves.

A lead-copper-vanadium mineral, evidently cuprodescloizite, has presented itself as a possible source of vanadium worthy of consideration. For this reason, an investigation into the metallurgy of the vanadium especially applied to this mineral was deemed justifiable.

A sample of this cuprodescloizite was obtained by the Bureau of Mines through the courtesy of Mr. L. C. Shattuck and Mr. Houle of the Shattuck-Arizona Copper Co. of Bisbee, Ariz., and to whom we are indebted for their kindness.

Difficult to Mine

It is claimed by those who have examined the mine that a considerable amount of this mineral is available but likely to present some difficulty in mining, owing to the nature of the deposit. The mineral is found in a large vug, or cavity, as a deposit on a brecciated quartz.

The quantity of ore in this deposit, although not available at present owing to the caved-in condition of the mine, is best indicated by an extract from a letter recently received from the Shattuck-Arizona Copper Co. and is as follows: "At one time in 1915, the vanadium-bearing ore was exposed on the 600 level for a length of 200 feet, average width 3 feet and total height 600 feet. In this block was estimated a tonnage approximately 3000 tons of ore averaging 10 per cent V_2O_5 (vanadium pentoxide)"; and "In addition to the so-called high-grade ores a large tonnage of ore assaying from 1 to 1½ per cent V_2O_5 is exposed."

The Mineral Described

The sample submitted to the Bureau of Mines consisted of a large sample weighing nearly 40 lb., and composed largely of the mineral deposited on hard quartzite fragments so as to form a cementing material. The mineral itself is admirably described by Mr. R. C. Wells[1], who examined a specimen several years ago and describes it as follows:

"The mineral occurs in the form of stalactites. The smaller aggregates radiate from a narrow base and end in round clusters ⅛ mm. in diameter. The larger growths occur in reniform masses several centimeters in diameter. The latter are coated with a red powder, but the smaller aggregates have an olive hue. The fractured surface of all varieties possesses a dark-brown luster and shows a radiating structure. The streak is a dark olive buff."

There is this difference, however, that the red powder, evidently vanadium pentoxide, occurs as a thin layer between the quartzite and the deposit of mineral itself, rather than being found as a coating on the mineral. The fractured surface also has more of a bluish-gray metallic luster than a dark-brown color.

Preparation of the Sample

The sample described was taken and ground to 20 mesh, and gave on analysis the following:

Insol	52.50 per cent
V_2O_5	8.06 per cent
CuO	7.31 per cent
PbO	23.02 per cent
Fe	2.36 per cent

From the above analysis it is seen that the ore would also be valuable as a lead and copper ore if found in any quantity. The iron was evidently introduced by the grinding, since scarcely more than a trace is present in the original sample. This was to be expected, owing to the extreme hardness of the quartzite and to the difficulty encountered in grinding it. The phosphorus and arsenic in the sample were not determined, but were shown to be present by qualitative tests. A screen test made on the sample gave the following figures:

Mesh	Per Cent
Through 20 on 40	17.38
Through 40 on 60	19.13
Through 60 on 80	8.48
Through 80 on 100	8.86
Through 100 on 120	3.53
Through 120 on 150	1.63
Through 150 on 200	6.23
Through 200	34.76
Total	100.00

Very little attempt was made to improve the grade of the ore by concentrating. Some attention, however, was given to the possibility of affecting some concentration by careful screening. From the nature of the ore it was thought that this scheme might possibly be applied.

The mineral is softer than the quartz and would consequently be expected to grind more readily and,

*Published by permission of the Director of the U. S. Bureau of Mines.

[1] *Amer. Jour. of Science*, 4, 36. 636-638. 1913.

therefore, could be separated from the quartz by proper screening. A test was made on a ground sample to determine the possibilities of this procedure. The results obtained are given below:

Mesh of Product	V_2O_5 Per Cent	Copper, Per Cent	Lead, Per Cent
Retained on 20	7.48	5.05	18.17
Passed through 20	8.06	5.95	21.37
Passed through 150	8.58	....	....

It is seen that the fine product passing the 150-mesh sieve is only of a slightly better grade than that of the material retained on the 20-mesh. From these results it would seem that the slight improvement in the grade of the ore is scarcely sufficient to justify the treatment.

As confirmatory of the above results, it was noticed that in preparing a sample of the 20-mesh material for analysis by grinding in an agate mortar and frequently screening off the fine ore a considerable portion of the mineral persisted with the quartz until practically all of the sample had been ground. From these facts it seems that concentration by screening could not be recommended.

Other methods of concentration were not tried for several reasons. First, the ore, since it contained 8 per cent of vanadium pentoxide, was already fairly high; and, second, since the gangue is a hard quartz, the grinding costs would be necessarily high, and therefore to be avoided. The coarse material would also facilitate filtering and be desirable to the final recovery of the lead in the subsequent sliming process. Some difficulty would also be encountered in slime losses, since the red powder of V_2O_5 would tend to be carried off as slime and would necessitate special treatment.

The mineral itself, neglecting the powder, could be easily concentrated as would no doubt be necessary on the low-grade material. The cuprodescloizite is fairly heavy, while the quartz is a light mineral. A rough test made by passing a small quantity of the ground sample over the Wilfley table confirmed the above assumptions and gave excellent promise of a good concentration and clean separation.

Methods Tried for Extraction of Vanadium

The object of experiments on this ore was to determine the best procedure for extraction of the vanadium and then to work out a method for recovery of the lead and copper if possible. Methods that were found ill-suited for a good extraction of the vanadium were given but little consideration. The schemes tried, with a brief statement of the results obtained by each, are given as follows:

1. *Leaching With Hydrochloric Acid:* Experiments were made with hot and cold dilute and concentrated hydrochloric acid. It was found that if used in large excess this acid decomposed the ore fairly well, but the vanadium was deposited on the insoluble residue as the oxide before the solution could be filtered. An extraction of about 70 per cent was obtained with the amount of acid commercially feasible.

2. *Leaching With Sulphuric Acid:* Experiments were made with dilute and concentrated sulphuric acid in the hot and the cold. The results finally obtained were found to be quite satisfactory, and are given later in this report.

3. *Treatment With Concentrated Sulphuric Acid Under Pressure:* These tests were made by mixing the ore with sufficient acid to make a thick paste and then heating in a capped iron tube for from 2 to 3 hours at 400 deg. C. Some of the experiments showed only a 15 per cent extraction, the best obtained being around 70 per cent. In one or two of the earlier tests which were made in a thick-walled hard glass tube, which burst before reaching 400 deg. C., an extraction as high as 85 per cent was obtained, a fact which proves that the high temperature and pressure are undesirable.

4. *Fusion With Niter Cake:* The preliminary tests were made with c.p. sodium bisulphate, which was later replaced by the commercial salt commonly known as niter cake. As a whole, the fusions with niter cake alone were found unsatisfactory, in that even by using as much as three and four times as much cake as ore, the extractions could not be raised above 85 per cent. It was found, however, since approximately two-thirds of the ore could be decomposed by heating it with an equal weight of the niter cake, that this fusion could be satisfactorily used as a preliminary treatment, followed by a sulphuric acid leach.

5. *Fusions With Soda Ash, Soda Ash and Caustic Soda, and With Soda Ash and Salt:* Fusions were made with the above mentioned fluxes to obtain a vanadium soluble slag. Carbon was added as a reducing agent to obtain the lead as a button. It was found that the amount of fluxes required to obtain a sufficiently fluid slag was very large, and the amount of vanadium extracted by leaching the slag with water was only from 65 to 70 per cent.

A straight alkaline leach was not tried on the ore, since the slag obtained in the above fusions after being pulverized and heated for some time gave practically the same conditions.

6. *Volatilization of the Vanadium as the Oxytrichloride With Chlorine and as the Tetrachloride With Hydrochloric Acid Gas:* From the theoretical standpoint, this method is the most ideal of all the methods tried. The vanadium would be recovered as a high-grade oxide, and the lead and copper in the tails rendered soluble in hot water. The treatment requiring chlorine would eliminate the arsenic, since the ore would have to be reduced with either carbon or hydrogen at a red heat, which would, no doubt, volatilize the arsenic. The hydrochloric acid gas treatment was found applicable on the original ore, but the arsenic was carried over with the tetrachloride. Both of these methods gave promising results on small samples of one to two grams, but when tried on larger samples gave very poor recoveries.

7. *Chloridizing Roasts With NaCl and With NaCl and Sulphur:* A few chloridizing roasts were made in an attempt to render the vanadium soluble. The amount of vanadium rendered soluble by this treatment was only a small percentage of the total. The preliminary tests gave such poor promise of success that this method of attack was given but slight consideration.

8. *Combination of Niter Cake-Sulphuric Acid Treatment:* This treatment is the one that was finally considered to be the most economical and, in general, the most satisfactory. Details and results are given more fully in other parts of this report.

Since the niter-cake fusion is given as a preliminary treatment of the ore, it was thought advisable to give a few of the results obtained in the tests. A considerable number of experiments were made to fix the conditions best suited for a maximum vanadium

extraction. The preliminary fusions were made with the fused c.p. bisulphate which was later replaced by niter cake. The results obtained are given in Table I.

TABLE I.

No. of Test	Weight of Ore	Weight of $Na_2S_2O_7$	Ratio Ore to Flux	Extraction V_2O_5, Per Cent	Remarks
1	10 g.	5 g.	2 : 1	11.3	Practically all of SO_3 driven off by blast.
2	10 g.	5 g.	2 : 1	38 0	Part of SO_3 driven off.
3	10 g.	5 g.	2 : 1	44.4	Heated only to fusion.
4	10 g.	8 g.	10 : 8	65.7	Heated only to fusion.
5	10 g.	10 g.	1 : 1	85.7	Heated only to fusion.
6	10 g.	12 g.	5 : 6	83.5	Heated only to fusion.
7	5 g.	7 5 g.	2 : 3	85.7	Heated only to fusion.
8	5 g.	10 g.	1 : 2	87.2	Heated only to fusion.

Another series of tests very similar to those given in Table I were made with niter cake, and the results obtained are given in Table II.

TABLE II.

No. of Test	Weight of Ore	Weight of Flux	Ratio Ore to Flux	Extraction V_2O_5, Per Cent	Remarks
1	5 g.	5 g.	1 : 1	44.1	Scarcely all of niter cake fused.
2	5 g.	5 g.	1 : 1	66.2	Heated only to fusion.
3	5 g.	5 g.	1 : 1	48.4	A little SO_3 driven off.
4	5 g.	5 g.	1 : 1	29.1	SO_3 driven off by blast.
5	5 g.	6 g.	5 : 6	70.6	Barely fused.
6	5 g.	7 g.	5 : 8	80.3	Barely fused.
7	5 g.	10 g.	1 : 2	85.1	Barely fused.

The results, in general, show that the extractions are a little lower in the niter-cake fusion than in the bisulphate fusion, a fact which is no doubt explained by the presence of free nitric acid in the niter cake. This effect could in a measure be offset by adding a small quantity of a suitable reducing agent.

From these results, it is seen that the best extraction is obtained when the mixture is heated only sufficiently long to melt all of the niter cake. On larger samples in which the heat is applied more slowly the fusion becomes almost a sulphatizing roast, since very little fusion takes place. On the small samples a distinct fusion is obtained when the heat is applied more rapidly. In general, the extraction is a little better on small samples than on the larger, but as is shown in Table V about two-thirds of the vanadium is consistently extracted with a ratio of 1:1. The extraction is poor if the heating is prolonged, even if the amount of flux is increased, as is shown in Table III.

TABLE III.

No. of Test	Weight of Ore	Weight of Niter Cake	Extraction V_2O_5, Per Cent	Remarks
1	25.0 g.	25.0 g.	56.0	Samples heated longer than advisable
2	25.0 g.	30.0 g.	61.1	Samples heated longer than advisable.
3	25.0 g.	35.0 g.	62.1	Samples heated longer than advisable.
4	25.0 g.	40.0 g.	54.3	Samples heated longer than advisable.
5	25.0 g.	45.0 g.	50.8	Samples heated longer than advisable.
6	25.0 g.	50.0 g.	54.3	Samples heated longer than advisable.

In order to determine the amount of acid that would be required to react with all of the bases, an analysis of the ore was made. The amount of acid thus required from a theoretical standpoint was calculated and found to be approximately equal to 30 per cent of the weight of the ore. Several series of tests were made using this amount of acid, which was gradually increased up to the amount necessary for a good extraction.

A considerable number of tests were made, varying the amount of acid and the time and temperature of heating. The results obtained are given in Table IV. As the quantity of acid used was insufficient to cover all of the sample, enough water was first added to moisten the ore. The acid was carefully added from a burette and the samples heated as indicated at a temperature of 175 to 180 deg. C.

TABLE IV

No. of Test	Weight of Ore	Cc. Acid H_2SO_4	Weight of Acid	Per Cent Excess Over Theoretical	Time Heated, Minutes	Extraction, Per Cent
1	10 g.	1.6	2.94	None	15–15	57.2
2	10 g.	1.8	3 31	12 5	15–15	61.1
3	10 g.	2.0	3 68	25 0	15–15	69.0
4	25 g.	4 0	7.36	None	60–15	60.4
5	20 g.	4 8	8 83	50 0	90–15	77.7
6	25 g.	6 0	11.04	50 0	60–15	82.3
7	25 g.	8 0	14 72	100.0	15–15	85 1
8	25 g.	8 0	14 72	100.0	30–15	90.1
9	25 g.	8 0	14 72	100.0	45–15	95.7
10	25 g.	10 0	18 40	150.0	15–15	93.5
11	25 g.	10 0	18.40	150 0	30–15	95.9
12	50 g.	20 0	36 80	150 0	45–15	94 4

The table shows that a 95 per cent extraction can be obtained with an amount of acid equal to twice the theoretical quantity. This fact was confirmed by a number of other tests. The first figure under the heading "Time Heated" refers to the actual time the samples were heated with acid alone and the second figure indicates the time of heating after diluting with 60 to 75 cc. of water.

Some trouble was encountered in the earlier experiments owing to the tendency of the vanadium to separate from the solution before the filtering could be accomplished. An attempt was made to eliminate this trouble by passing a slow stream of sulphur dioxide through the solution during the treatment. This procedure was found to prevent the precipitation of the vanadium and to increase the extraction a small amount, but it was later found to be wholly unnecessary, in that the same object could be attained by adding only sufficient water to permit filtering and washing. From these results it would be possible to obtain an extraction of 95 per cent by using 1172 lb. of 66 deg. B. sulphuric acid per ton of ore.

Treatment by Combination of Niter-Cake Fusion and Sulphuric Acid Leach

This treatment consists of subjecting the ore to a preliminary fusion with niter cake followed by a hot-water leach, then treating the residue with sulphuric acid. As previously stated, it was found that by heating the ore with an equal weight of niter cake approximately two-thirds of the ore could be decomposed and

TABLE V.

Niter-Cake Fusion Treatment								H_2SO_4 Leach of First Residue					Results		
				Extraction						Extraction			Combined Extraction		
No. of Run	Weight of Ore, Grams	Weight of Niter Cake	Weight of Residue	Per Cent V_2O_5	Per Cent Cu	Per Cent Pb	Residue, Per Cent Pb	Cc. Acid	Weight of Acid, Grams	Weight of First Residue	Per Cent V_2O_5	Per Cent Cu	Per Cent Pb	Per Cent V_2O_5	Per Cent Cu	Per Cent Pb
1	48	48	42.5	70.20	74.50	58.3	24.49	6.8	12.62	41.5	22.60	24.40	25.5	92.80	98.9	83.8
2	100	100	89.8	62.75	65.78	66.3	24.56	a. 3.70	6.82	20.0	34.40	33.15		97.15	98.9	
								b. 3.08	5.66	20.0	28.60	28.50		91.35	94.3	
								c. 2.47	4.55	20.0	28.12	26.70		90.37	92.5	
								d. 1.85	3.42	20.0	19.36	23.41		82.11	89.2	
3	100	100	89.7	59.70	63.1	59.9	23.40	a. 3.70	6.82	20.0	30.90	32.50		90.60	95.60	89.0
								b. 3.08	5.66	20.0	27.15	30.20		86.85	91.50	
								c. 2.47	4.55	20.0	26.70	23.85		85.40	86.95	
								d. 1.85	3.42	20.0	25.20	22.70		84.90	85.80	82.5

the corresponding values extracted. The remaining values are then extracted by leaching the residue with about one-half as much acid as is required in the straight acid treatment. This procedure substitutes an amount of niter cake worth about two-thirds the value of the acid that would be required. This method would entail a slightly increased cost for labor and equipment, but the utilization of the cheaper chemicals would no doubt still render the use permissible from the standpoint of economy.

Experiments With Niter-Cake Treatment

The initial treatment with niter cake should be made under conditions approximately the same as those found to be the most desirable under the experiments on that fusion. The ore should be mixed with the pulverized niter cake and heated barely to fusion. Sufficient water to break up the ore and to permit washing should be used, and boiling should not be continued any longer than necessary to accomplish this. In the experiments to determine the minimum amount of acid to treat the residue from the fusion, the residue was dried and divided into portions for the tests. In the working process the drying would be unnecessary, since the acid could be added directly to the moist residue. A fairly good idea of the results obtained by this method can be had by reference to Table V.

The percentage of the lead remaining in the residues as sulphate was not determined in all cases, owing to the difficulty of recovering the residues quantitatively. In practically all instances where analyses were made, more particularly on the smaller tests on which the residues could be better collected, the percentages of lead as sulphate ran a trifle lower than the vanadium extracted, so that a close approximation can be made in this manner. It was originally planned to allow the lead to remain in the residue, and to concentrate it by sliming, as is being successfully done with radium-barium sulphate in radium extraction, so that the lead would be obtained either as a high-grade lead residue or as a crude lead sulphate.

Result of Actual Sliming Test to Determine Recovery of Lead Sulphate From Residues

An actual sliming test was made to determine the possibilities of recovering the lead sulphate from the residues. A typical sample of the residue obtained by treating a quantity of the ore with concentrated sulphuric acid was placed in a large beaker and water added. The mixture was then violently stirred in order to put the lead sulphate in suspension and then decanted. This procedure was repeated several times and the slimes allowed to settle and were recovered as concentrates. The test gave the following results:

	Grams
Weight of ore used	400.00
Weight of residue obtained	330.00
Weight used for sliming test	300.00
Weight recovered as slimes	165.00
Weight recovered as tails	132.00
Percentage lead in original ore	21.67
Percentage lead in residue	25.08
Equal to 28.89 per cent $PbSO_4$	
Percentage lead in slimes	43.09
Equal to 49.76 per cent $PbSO_4$	
Percentage lead in tails	3.52
Equal to 4.06 per cent $PbSO_4$	
Percentage lead recovered	94.70

The test required considerable water to obtain a good recovery, but this would not be a serious objection commercially, since the same water could be used repeatedly. It would also be desirable in that it would remove the last traces of vanadium not previously washed out, which could be allowed to accumulate in solution until present in sufficient amount to recover.

The values given in Table V for lead extracted were determined by dissolving the lead from the residues with ammonium acetate, so that the figures really represent the lead present as the sulphate. It was assumed that the lead converted to the sulphate could be considered as extracted, since it would be subject to recovery in the subsequent sliming process.

Recovery of the Vanadium From the Solutions as Iron Vanadate

The vanadium recovered by this treatment would be in the form of iron vanadate containing as a minimum about 35 per cent V_2O_5. In the experiments made, a product of variable V_2O_5 content was obtained according to the care used in neutralizing the acid solution and time of boiling. The iron necessary for the precipitation was introduced by adding scrap-iron, which simultaneously replaced the copper. The vanadium was then thrown out from the solution by carefully adding a strong solution of caustic soda until the solution gave but a very slight acid reaction, and then boiling for two to three hours. By this procedure some samples of iron vanadate containing as much as 50 per cent V_2O_5 were obtained with scarcely any of the vanadium passing through into the filtrate as indicated by qualitative tests with hydrogen peroxide.

The copper thrown out of solution by the iron was at first in the form of bright flakes which gradually darkened as the replacement continued. This copper when filtered off and dried was almost black, due no doubt to the impurities from the iron and arsenic from the ore. The cement copper on analysis gave a copper content of 92 per cent, which would easily be converted to the pure metal in the reverberatory furnace.

Some difficulty was encountered with the copper, which must be thoroughly removed from the solution to prevent its being carried down in the iron vanadate. It was found, however, that by permitting the scrap-iron to remain in the solution for a number of hours practically all of the copper could be thrown out of the solution and the iron vanadate then obtained would be nearly free from copper. This procedure allowed a considerable excess of the iron to go into the solution, a fact which did not materially affect the grade of the precipitate, and is objectionable only from a standpoint of economy of iron. As previously stated, the real important factor in controlling the grade of the iron vanadate is the care used in the neutralization with caustic soda.

The neutralization also consumed a considerable quantity of caustic soda, which would be expected, by the necessity of using so large an excess of acid to obtain a satisfactory extraction. This could in a measure be overcome by boiling off a portion of the free acid, and also suggests the possibility of recovering some of the acid.

As an example of the products obtained, by varying the amount of alkali used in the neutralization the following figures are given:

No. of Test	Alkali Added Cc.	Grade of Ppt. Obtained, Per Cent V_2O_5
1	24.99	50.52
2	30.30	48.55
3	32.90	30.37

(1 cc. alkali = 0.08644 grams NaOH)

In these tests three aliquots of 50 cc. each of a solution containing 0.0142 g. of V_2O_5 were taken. The procedure in these experiments was as follows: One-fourth, one-half and three-fourths respectively of the acidity of the solution was neutralized before adding the iron strips to replace the copper. After the copper was filtered off, the remainder of the alkali was added, and the solutions boiled for two and one-half hours. There is little difference between numbers 1 and 2, but evidently too much alkali was added to number 3.

Two Processes of Neutralization

Two procedures were tried in the neutralization: (1) To neutralize a portion of the free acid before adding the iron strips for the purpose of lowering the iron consumption, and (2) adding the iron directly to the acid solution and neutralizing after the removal of the copper. So far as affecting the grade and recovery of the vanadium, there is really very little preference, but (1) is probably more desirable for the saving in iron. A satisfactory iron vanadate is obtained by both methods.

ESTIMATE ON VALUE OF ORE AND COST OF TREATMENT

Value of ore:		
21.37 per cent lead	427.4 lb. at $0.07 per lb.	$29.90 per ton
5.95 per cent copper	119.0 lb. at .25 per lb.	29.75 per ton
8.06 per cent V_2O_5	161.2 lb. at .75 per lb.	120.90 per ton
Total value		$160.55 per ton
Costs for Treatment by Sulphuric Acid Leach per Ton of Ore:		
1172 lb. of acid at $30.00 per ton		$17.50
485 lb. of caustic soda at $0.04 per lb.		18.40
150 lb. of scrap-iron at $0.01½ per lb.		2.25
Expense for mining, grinding, labor for treatment, depreciation, etc.		15.00
Total		$52.15
Costs for Treatment by Sulphuric Acid Niter Cake Method:		
2000 lb. niter cake at $5 per ton		$9.00
600 lb. acid		5.00
Caustic soda required		18.40
150 lb. scrap-iron at $0.01½ per lb.		2.25
Mining, milling, etc.		15.00
Total		$49.65

The costs of mining, milling and labor and materials for treatment, depreciation, etc., are variable factors, depending upon the capacity and location of the plant; but it would seem that under the most adverse conditions the cost should not be greater than $15 per ton of ore.

By reference to the value of the lead and copper present in the original ore, and from the extractions and recoveries considered possible, it would seem justifiable to claim that the return from these, recovered as by-products, would more than pay for the whole treatment of this ore.

Looking at the process from the standpoint of recovering the vanadium only, and assuming a 90 per cent recovery, the value of the product would be:

90 per cent of 161.2 lb., or 144.08 lb., of V_2O_5	$108.80
Cost of treatment by acid alone	52.15
Cost of treatment by niter-cake acid	49.65

It is evident that this ore would permit an expensive treatment, but, of course, would not warrant it simply for that reason. Even if the costs of treatment, which have been given above, were to be doubled, which would be very unlikely, the methods could still be applied to an ore of this value.

Summary

1. The recovery of the vanadium in cuprodescloizite by volatilization in a stream of chlorine or hydrochloric acid gas presents some interesting possibilities, but results obtained were unsatisfactory.

2. The vanadium in this mineral responds more readily to acids than to alkalies.

3. The straight sulphuric-acid leach gives quite satisfactory extractions and permits a good recovery.

4. The niter-cake fusion is undesirable alone but applicable as a preliminary treatment in a combined niter-cake-sulphuric acid process.

5. Copper or other metals undesirable in the iron vanadate must be removed to prevent contamination of the iron vanadate.

6. Boiling of precipitate after neutralization of acid solution is essential to obtain a good grade of iron vanadate.

7. A good grade of iron vanadate can be secured even in the presence of a large excess of iron if the neutralization is carefully controlled.

8. An ore, or concentrate, of the composition of the sample used can be economically treated and possibly at a cost less than the value of the by-products.

I wish to thank Dr. R. B. Moore, under whose direction this work was done, and Dr. S. C. Lind, for many helpful suggestions.

The Edgewood Arsenal

The enlisted men at Edgewood Arsenal, Edgewood, Md., published during the war *Chemical Warfare*. Vol. 1, No. 5, for March, 1919, is a souvenir edition containing the story of Edgewood in text and illustrations. Complete data are given on the production of toxic materials and the filling of shells, grenades, Livens drums and drop bombs. The book contains a wealth of photographs showing the interior equipment of plants, and a complete set of photographs of officers in charge. The book is a credit to the editor in chief and his associates and a fitting tribute to one of the most important branches of the service.

The Oxidation of Ammonia*

Review of the Early Investigations Beginning in 1839 With Kuhlman—Ostwald Process and Apparatus —Improvements Made in Catalyst Screens, Platinum Activation to Foreign Gases Such as Acetylene and Phosphine—Cyanamide Process at Muscle Shoals

By W. S. LANDIS

JUST when ammonia was first intentionally converted into nitric acid or nitrate products I have been unable to learn. Soil bacteria have been doing it for ages. Since the invention of gunpowder, with its increased demand for nitrates, man has endeavored, in places, to assist such bacterial action and thereby lighten his task of recovery. The direct oxidation of ammonia by air through chemical or electrical action seems to have been a scientific curiosity more than a hundred years ago. Eighty years ago Kuhlman, a German technical chemist, after describing at length some very interesting experiments of his own, concluded with the significant remark, "While under present conditions the transformation of ammonia into nitric acid with the assistance of platinum and air has no great value, yet the time will come when it may be of commercial importance."

This commercial prophecy, presented so many years ago, has been a long time reaching fulfillment. Ten years after its utterance, when Chilean nitrate was reaching Hamburg in quantity and prices of nitrate began to decline, its fulfillment must have looked hopeless, as well as during the long years when ammonia prices and nitrate prices were strictly competitive and there was no margin of difference to pay for the transformation. Nevertheless, in the eighty years intervening since the Kuhlman publication, and in spite of the Chilean developments, the Norwegian synthetic nitrate production and the difficult commercial situation, the problem has been attacked in a fairly energetic and persistent manner.

Two Small European Plants

At the outbreak of the European war there were two small plants in Europe capable of transforming ammonia into nitric acid, neither of which, however, had shown sufficient commercial possibilities in the five or six years of operation to warrant further expansion. One of the plants was in Germany, but not operating with any regularity, and never had any production capacity to speak of. Not even the military situation had awakened more than a passing interest in the subject in that country. The long-anticipated war was to be short. There were at hand enormous stores of munitions that had been accumulating for a dozen years. The country maintained supplies of over half a million tons of Chilean nitrate at all times, and peace was sure to be dictated within forty or fifty days after the declaration of war. Why should the oxidation of ammonia be of pressing importance?

But to return to our history of development, Kuhlman in 1839 passed a mixture of air and ammonia through a glass tube containing spongy platinum. At ordinary temperatures no action was observed, but when heated to 300 deg. C. the platinum glowed and with a considerable excess of air in the gas mixture, vapors of nitric and nitrous acids were evolved. At higher temperatures nitrous acid in fairly pure form was obtained. With excess of ammonia the corresponding salts were formed. No quantitative data of any sort were included in the report.

Early Discoveries

Eighteen years later the work was taken up by Schonbein, who found that if spongy platinum was saturated with aqua-ammonia and introduced into air, or preferably oxygen gas, slow oxidation to ammonium nitrate took place at ordinary temperatures. Dense platinum caused this oxidation only at higher temperatures. Finely divided nickel and copper also brought about a similar oxidation of ammonia.

Schonbein was probably the first to use dense platinum in the form of wire. He heated a platinum spiral to just below redness and inserted it into a flask which had been rinsed out with a strong ammonia solution. The gas in the flask turned iodide-starch solution blue and the flask filled with a white fog. Powdered copper reacted in the same way.

Passing over the next few years briefly: Tessie du Motay in 1871 obtained nitrates by passing a mixture of air and ammonia over lead manganate, permanganate or bichromate, heated to 350-400 deg. C. Liebig obtained a similar nitrate by using iron oxide. Wëith in 1874 mixed ammonia gas with ozone and hydrogen peroxide for direct oxidation. Twenty years later Siemens & Halske took out a patent on the use of ozone for this purpose. In 1912 Jones and his co-workers of the Semet-Solvay, following somewhat the outline of du Motay, developed the oxidation by the use of alkaline earth plumbates. Nothing commercial has come to date from any of the above schemes and a great many others along the same lines not enumerated here.

One more name of importance in this early work is that of Warren, who about 1890 passed an ammonia-oxygen or air mixture over platinized asbestos and obtained ammonium nitrate. Although nothing commercial came directly of his work, its publication undoubtedly assisted in causing the cancellation in the German patent office of the celebrated Ostwald patents, which process I shall refer to next.

The Ostwald Process

Twenty-five years ago Wilhelm Ostwald undertook a study of the oxidation of ammonia. He paid much attention to the work of Kuhlman and determined to study the reaction from the scientific standpoint, as nothing along those lines had been done in the fifty years elapsing since Kuhlman's original publication. In his usual careful manner he studied the fundamentals underlying the reaction, and the reading of his exhaust-

*Paper read at the meeting of the American Electrochemical Society in New York, April 3-5, 1919.

ive reports on his investigations would have been of great assistance to many of the recent workers in this field.

Ostwald in general showed the futility of attempting to use spongy platinum as catalytic material, also the necessity of quickly removing the products of the oxidation out of contact with the catalyst. He showed that platinum black was the poorest sort of a catalyzer, yet in spite of this finding, several recent investigators have unsuccessfully attempted to prove otherwise. He noted the activation of dense platinum through operation under special conditions, and particularly the advantage of using such form of catalyst over other types. He further determined the most suitable mixture of air and ammonia for efficient oxidation, and of the utmost importance, that for such mixture a supply of heat above that directly generated by the reaction was necessary for continuous operation.

Ostwald's Apparatus

The result of this work of Ostwald was the building of two oxidation plants of small capacity, the first of which went into operation in 1908. The early apparatus installed underwent several modifications, one of the later type being shown here (Fig. 1).

The exterior tube is of "heat"-resisting and insulating material, and the interior tube of nickel. The

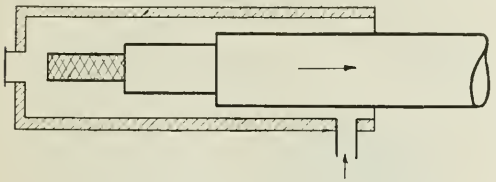


FIG. 1. LATER TYPE OF OSTWALD'S APPARATUS

catalyzer is built up of narrow strips of platinum foil, alternately crimped and flat, thereby producing a series of short tubes. The ammonia gas-air mixture, in the proportions of approximately 10 per cent ammonia, enters the exterior tube at the right, passes to the left in the annular space and out through the red hot catalyzer and nickel tube. This tube is made in sections to enable cheap replacement, as the sections wear unequally. The hot products of combustion lose their contained heat through the nickel tube to the oncoming raw mixture and so serve to keep the apparatus in operation. The apparatus is started by the use of a gas jet at the catalyzer end, or by burning hydrogen gas around the nickel tube. The catalyzer runs very hot, around 800 deg. C.

Process in England

A recent form of somewhat similar construction developed by the Barton interests in England since the outbreak of the war uses a nickel tube about 3 in. in diameter and 10 ft. long. The catalyzer consists of a bundle of spirals of platinum foil hung in the top of the tube. The life of the catalyzer is less than three months. One troy ounce of platinum oxidizes only about 1.5 lb. of ammonia per hr. in this apparatus. The reported efficiency is 90 to 95 per cent, but a study of a large installation in France where cyanamide is converted to ammonia and that to nitric acid shows only 60 to 70 per cent for the whole, and since ammonia production from cyanamide can be carried out at a nitrogen efficiency of 96 to 98 per cent, depending upon the design of the apparatus and the skill of operation, the oxidation efficiency itself must be very low. I have no direct figures on this catalyzer efficiency.

Ostwald himself reported that his plants obtained an oxidation efficiency of 85 per cent, but my attempts to verify this over long-time operation have been fruitless. I am of the opinion as a result of my investigation that 75 per cent would be nearer. He passed his gas over the platinum at a speed of 5 m. per sec. and left the gas in contact with the catalyzer about 0.004 sec., both figures being far outside the region of our later work, and thereby confirming the low obtained efficiency of his process.

Kaiser, a Siemans & Hälske chemist, next attacked the problem. He used a platinum gauze for catalyzer and at times directly heated the air, at times activated it by silent discharge, or preferably both, then added the ammonia and passed the mixture through platinum gauze. The literature on the process is so complex as to be really unintelligible. At any rate he reported an efficiency of 150 to 220 per cent, claiming the activated air enabled the attainment of such a high temperature in the gauze catalyzer as to cause part of the nitrogen content of the activated air to unite directly with oxygen. His work was repeated by Kochman, who reported efficiencies of only 105 to 115 per cent. The answer, we later found, lay in the method of analysis used.

Europe's Premature Notice of Entering Nitrate Field

In 1908, after the first few cyanamide plants abroad were in operation, the European interests backing them placed the world on notice that they were prepared to enter the nitrate field, which up to that time had been controlled by Chilean nitrate and some small arc-process product. It looks as if this notice was based on the work of Frank and Caro which shortly afterward appeared in the form of patent literature. If so, it was very premature, as that early process never came into commercial development. The process in question used a mixture of cerium and thorium oxides as catalytic material. Like many other processes of like kind using powdered catalyzers, the process failed because the catalyst sintered and became impermeable after short use. Even as late as 1912 work was still being done on this process, the latest development being a catalyzer consisting of 99 per cent ThO_2 and 1 per cent CeO_2 and showing 65 to 70 per cent efficiency at best.

A Combination Process Evolved

The Ostwald patents, after allowance, had been cancelled in Germany and the oxidation process left open to all. Frank and Caro, after the failure of their rare earth catalyzer, turned to a combination process, passing the ammonia-air mixture through a platinum catalyzer, and then through a granular mass of cerium and thorium oxides treated with platinum chloride, and resting on a nickel screen above the platinum gauze. The experiment, carried out in a small apparatus using a gauze 4 in. in diameter, showed efficiencies of from 7 to 78 per cent, with an average of less than 50 per cent.

In July, 1913, attention of the German cyanamide interests was directed to the use of platinum alone as a catalyzer, and the best features of all previous experiments were assembled in a new type of apparatus. The preheating system of Ostwald, with the direct heating, and the gauze of Kaiser, were incorporated in the ap-

paratus shown in Fig. 2. Ammonia could be introduced with the air or at various distances under the gauze. The gauze (1060 meshes per sq.cm. and wire 0.06 mm. diameter) was only 5.5 cm. diameter, not quite all of which was active. From the meager data which came into my possession efficiencies of 41 to 91 per cent were obtained, but as ammonia passing the screen unaltered was not regarded as lost, these figures are subject to 23 to 27 per cent deduction for unaltered ammonia, making actual oxidation efficiency at a maximum only about 65 per cent. Nothing came of this work and in September and October, 1913, a new setup of the same apparatus was made. By regulating the ammonia-air mixture to between 1 : 10 and 1 : 15 by volume an average efficiency of 85 per cent less 6 per cent for unaltered ammonia was obtained.

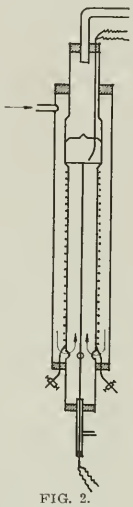

FIG. 2. OSTWALD-KAISER MODIFICATION APPARATUS

In November a larger diameter apparatus using a gauze 10 cm. diameter was put into service, but the results were not particularly encouraging, rarely exceeding 80 per cent efficiency and most of them considerably below that figure.

Experiments were carried out with smooth gauze and with gauze coated with platinum black. The latter showed little or no advantage over the smooth platinum, although slightly less ammonia seemed to pass through unchanged. Various alloys of platinum were tried and it was noted that the presence of iridium had a particularly deleterious effect. Further experiments were carried out using multiple gauzes (that is, two and three gauzes superimposed), but in no case were oxidation efficiencies as high as 85 per cent obtained. The combination of multiple gauzes and oxides of cerium and thorium gave lower results than the platinum alone.

The effect of mesh of the gauze was also studied and there was little or no difference noted in the behavior of a gauze with 3000 meshes per sq.cm., as against one with 1060 meshes. Acetylene, and also oxygen, were added to the air, but better results were obtained with air alone than with any of the mixtures, though we later, in this country, obtained different results on enriched air.

External Heat Decided On

At the conclusion of these experiments, about the end of January, 1914, this investigation on the oxidation of ammonia had not brought out anything of commercial value. The experiments were critically reviewed and it was concluded that the hot gauze radiated heat to the oncoming ammonia-air mixture and decomposed some of the ammonia. This was emphasized by the necessity of preheating the gases before they arrived at the gauze. It seemed necessary to supply external heat in some way to maintain the reaction, and it was, therefore, decided to employ electric energy transformed into heat directly in the gauze itself, to meet this deficiency of energy, and at the same time to use a cooler in front of and in as close contact with the gauze as possible, so as to bring the ammonia in the shortest possible time from the ordinary temperature to the reacting temperature, which is around 75 deg. C. The apparatus shown in Fig. 3 was constructed to accomplish this result. A long strip of platinum gauze was folded as shown and the intermediate space blocked by mica strips cemented to the gauze. This was placed 1 mm. above a circle of heavy nickel gauze, which in turn was soldered to a water-cooled copper ring. The apparatus was only a few inches in diameter, but it showed very good results, running slightly above 85 per cent in conversion efficiency. It was next duplicated on a larger scale in which the gauze had an area of 660 sq.cm. This apparatus was put into service, but ran only a few hours, when it failed mechanically, and it at no time showed an efficiency of oxidation of above 80 per cent, although the experiments carried out were the most carefully conducted of any performed.

The general program upon which this work was carried out was entirely different from that of similar investigation work as we do it in America. Strange to say, the German experts in charge of it did not seem to devote much time to analysis of the problem from from a theoretical or from a physical-chemical standpoint, but instead devoted their attention to the construction of most elaborate and intricate apparatus, in which the principles of chemical engineering were

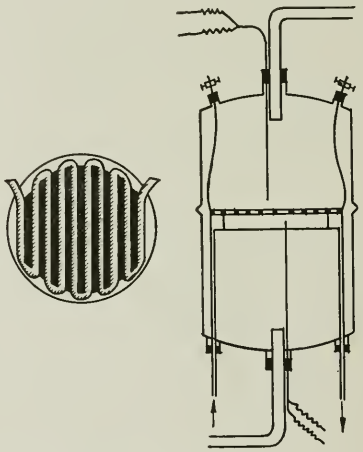

FIG. 3. ELECTRIC HEATED GAUZE APPARATUS

sacrificed to such external details as convenient existing electrical and mechanical conditions. There had not been a cleanout analysis of the problem made, as far as I would find up to the time I left Germany, in November, 1914.

Another Type of Apparatus

The construction of a different type of apparatus in which more attention was paid to chemical details next followed. A single sheet of gauze 65 x 25 cm. was especially made for this work, and very great delay in its manufacture was experienced. This gauze was housed in a metal box lined with aluminium, as shown in the detail in Fig. 4. The platinum gauze itself rested upon threads of asbestos, which in turn were carried on a nickel gauze. This nickel gauze was soldered to a frame of copper tubes through which water could be circulated. The apparatus was connected electrically to a source of low-voltage current through a rheostat

and anhydrous ammonia mixed with air was passed upward through the cooler and the gauze.

On Oct. 14, 1914, this apparatus was placed in operation. There was recovered, in the form of nitrates and nitrites, equivalent nitric acid to the extent of approximately 53 per cent of the equivalent ammonia fed to the apparatus. The apparatus failed because the gauze warped away from the cooler in places and this irregular distance resulted in very non-uniform heating. Conditions did not permit my continuing the study of this experimental work, but at the final conference in which I took part I suggested that the whole apparatus

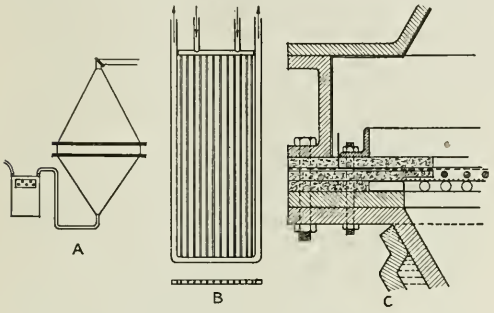

FIG. 4. A. GENERAL ASSEMBLY. B. COPPER WATER COOLER. C. DETAIL OF ASSEMBLY

would operate much better if the coolers as installed were abandoned entirely and the whole catalyzer box turned upside down. This advice was not at the time favorably received, but I believe that later, after my departure from the scene of the experiment, it was adopted and efficiencies of between 80 and 87 per cent were obtained.

This ended my direct contact with this early foreign experimental work on ammonia oxidation. The impressions I received were not encouraging, as I had not seen an apparatus function for more than a few hours at a time. The highest efficiency of conversion of ammonia to nitric oxide obtained in my presence had been only 53 per cent, and no attempt had been made to recover the nitric oxides as nitric acid, but only as nitrate-nitrite.

Further German Development

A record of further German development has been difficult to compile. On returning to Berlin I found that the commission in charge of this work had called in a new engineer, one I had not met before, but whom I knew by reputation in nitric acid work. His catalyzer was small, and consisted of a frame of refractory material about 4 in. square and ¼ in. thick. Two of these were wrapped with fine platinum wire, very close but not touching, and arranged one over the other so wires crossed at right angles. This gave the gas contact four times with the platinum in a single passage through the apparatus. The frames were arranged in a suitable housing, 24 units to a group. Each unit was supposed to make 230 g. nitric acid per hour, and consumed 4.5 amp. at 90 volts. Mechanically the apparatus was very well designed, but unfortunately it possessed a serious fault in using successive layers of catalyzer not in immediate contact with each other. This arrangement of platinum has never proved satisfactory from an efficient operating standpoint.

The writer is certain that on Jan. 1, 1915, with the exception of the old Ostwald plant, there had been nothing new erected in Germany for the oxidation of ammonia. A year later, however, very considerable installation of ammonia oxidation plants had been made, and it seems from the strong hands into which the electrically heated catalyzer had fallen that this made the greatest progress. It is believed that by the end of 1915 some form of an electrically heated catalyzer unit had been developed which was oxidizing at the rate of about 15,000 tons of ammonia per year. It is quite possible that this figure was much underestimated. In 1917, it is believed, the ammonia production in Germany had increased to around 300,000 to 400,000 tons, part of which was consumed in fertilizer, part in the direct production of ammonium nitrate and part in the oxidation of ammonia. Just how this division was made I do not know and have made no serious attempt to learn.

During my stay in Germany I found little or no information on the converting of the nitric oxide obtained from a catalyzer into nitric acid. Much of the apparatus proposed was what would be called small-scale work in this country, consisting as it did of towers of chemical stoneware, tourills and such equipment. With such apparatus for condensation, the units must have been small and inefficient, but on the other hand this type of construction lent itself to ease of assembly and a consequent great saving in time of construction. Also much of the nitric oxide was turned directly into sodium nitrate, that being a comparatively simple and easy problem. It further lent itself to the shipment of nitrate to the various powder plants already provided with the old niter pot equipment. In fact it is believed that this conversion to nitrate occurred to a very large extent throughout the war.

Imminence of War Arouses Interest Here

Toward the end of 1915, when it looked very much as if the trend of events was such that the United States was ultimately to be forced into the war, renewed interest took place in this country in the oxidation of ammonia as a source of nitric acid, and early in 1916 the writer was authorized by the American Cyanamid Co. to proceed with the design and construction of an experimental plant for studying the ammonia oxidation problem along the lines of commercializing what had heretofore been a laboratory curiosity. A considerable latitude in the choice of process was permitted, but it was essential that all equipment to be used must be capable of construction in this country. As to raw materials, we were permitted to make use of any form of ammonia on the market, but naturally we were partial to that produced from cyanamide because of a number of apparent advantages which this form of gas was then believed to possess. I am going to sketch briefly here the method of attack of the problem confronting us, as I believe the details will be of interest.

Method of Attack on Problem

The chemistry of the problem from a quantitative standpoint may be represented by the following equation:

$$4NH_3 + 5O_2 = 4NO + 6H_2O$$

This reaction will take place only in the presence of a suitable catalyzer, of which, from a study of all the previous work, platinum appeared to be the best. It is operative between 700 and 800 deg. C., giving its best results at about 750 deg. C.

The best proportion of air and ammonia for most efficient oxidation was reported by Ostwald to be a mixture containing about 10 per cent of ammonia. He, however, also expressed the opinion that a very large excess of air was advantageous. The small-scale work abroad seemed to show that an 8 per cent mixture was the most efficient to use, and we subsequently confirmed this in our large-scale work. We, however, later learned that the 8 per cent mixture was probably not the most economical for operation and preferred to work with about a 9 per cent concentration.

The combustion of a 10 per cent mixture will yield a theoretical temperature of 665 to 690 deg. C., the difference being due to variations in thermo-chemical constants used in the calculation. Assuming that the catalyzer must operate at around 750 deg. C. and that it will always radiate some heat, it is readily seen that it is absurd to consider attempting to operate the process without the addition of further heat to the catalyzer. With an 8 per cent mixture the temperature of combustion is theoretically only 550 to 580 deg. C.

The reaction

$$4NH_3 + 3O_2 = 2N_2 + 6H_2O$$

also takes place if the catalyzer is not operating properly, either due to composition or construction, or to other causes. The theoretical temperature of the flame corresponding to this reaction when using a 10 per cent ammonia mixture is 915 deg., using Nernst's data. This is somewhat higher than the actual temperature required on the screen. It is, therefore, seen that it is theoretically possible to operate the catalyzer only if from 25 to 40 per cent of the ammonia carried to the screen is burned to nitrogen, unless one has provided additional heat to the screen supplied either by regenerative methods or derived from an independent outside source.

Determining the Best Process

In looking over the methods of supplying this required heat to the catalyzer, the regenerative process of Ostwald demanded heating of the reagents to about 300 deg. C., and as at that temperature ammonia is subject to decomposition, the regeneration process did not look technically sound. We also questioned the control of a self-regenerative system in view of our lack of knowledge of the exactness of this control requirement of the process. The direct heating scheme used by Kaiser required the combustion of additional fuel and seemed to have no apparent advantages of any sort over the Ostwald system. We dismissed his so-called activation of air as of no value.

The only other method that appeared feasible to us was the direct electric heating of the catalyzer itself, and since the energy required is not very great and its cost only a very small fraction of the total operating expenses of the plant, we finally decided to adopt it.

Our next concern was the type of catalyzer. Both Kaiser and Caro had used the woven gauze or screen type with some degree of success, even though many advantages were claimed for the wire-wound frame. We adopted the screen as our first type of catalyzer and designed two forms, one of 80-mesh gauze and 0.0025-in. wire and the other of 100-mesh with wire of 0.0015 in. diameter. This gauze was to be of purest platinum, free from base metals and containing not over 0.05 per cent iridium. Three screens of each type, 13 in. wide and 26 in. long, were obtained from the American Platinum Works. The weaving was not particularly uniform, and we soon learned that the platinum contained nearly ten times the amount of iridium specified, all of which caused much trouble in the early days of our work.

Electrical Equipment

From the specifications of the gauze we figured out our electrical equipment, which was in itself quite an intricate problem in view of the lack of data on electrical conductivities of such materials as platinum gauzes. The current was received at the laboratory at 440 volts, 3 phase, 60 cycles, and distributed at this voltage for motor circuits. A portion was transferred down to 110 volts for lighting and catalyzer service, and to each catalyzer was attached an individual transformer rated 110 v. / 15.0-17.5-20.0-22.5 volts. In the high tension side was included 3 resistance grids with short-circuiting switches and a 25-point rheostat of the same total resistance as a grid. The resistance system was calculated to control the voltage on the low side of the transformer in steps of 0.05 volt over a total range of five volts or two transformer taps. This electrical system was completely revised and both cheapened and simplified in a later installation.

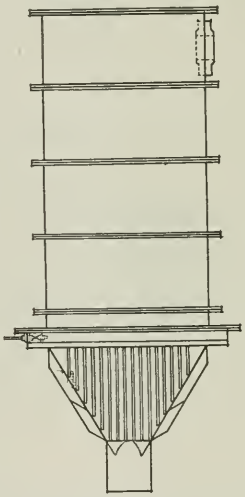

FIG. 5. MODERN CATALYZER UNIT

The catalyzer was housed in an aluminium box rectangular in section. It was stretched in a tray and packed in asbestos board, above which was assembled the sections of the box. We determined to pass the air mixture downward through the hot catalyzer, believing that method to insure more uniform distribution and flow. This necessitated some height of tower over the gauze, and not knowing just how high this should be, we built the housing in sections, each a foot high, making them interchangeable and providing four sections to each catalyzer unit. An assembly of the tower is shown in Fig. 5. Between the upper sections we placed an aluminium gauze of fine mesh and heavy wire to assist gas distribution, and at the same time carry heat to the side walls, where it was dissipated. The 4-ft. high tower seemed to be just right and has not been changed since the original design, except to eliminate the sectional feature in the later and more permanent installations. The catalyzer trays were all interchangeable and enabled us to repair and change gauzes with very little interruption to operation. After getting into operation we did not find it necessary to complicate the apparatus with a cooler, for while we believe in the use of a proper cooler, we could not design a satisfactory one.

Apparatus Performs Satisfactorily

Besides the oxidation equipment, the plant was equipped with an autoclave and ammonia apparatus for

the production of ammonia from cyanamide, gas holders and most complete measuring and indicating apparatus. Also oxidation, cooling and absorption towers for the recovery of nitric acid. Nothing was left to chance and for our efforts spent on the elaborate design we were amply repaid, for with the exception of the first platinum screens and their terminals, every piece of apparatus installed performed to the highest expected degree.

The first screens being delivered during the erection of the plant, we took one of them to the cyanamide plant in Canada and tried it out there on a small scale, absorbing the products of the reaction in caustic soda. We had learned from Ostwald that activation of the platinum was necessary, but we did not then know what it meant or how to obtain it. After running about two weeks with results showing better each day, we finally, on April 24, 1916, obtained an efficiency of oxidation of 91 per cent. In this series of experiments the highest figure obtained was 92.4 per cent, at a rate of 2 lb. NH_3 per hr. per sq.ft. of screen. The screen used weighed about 1.5 troy ounces per square foot.

While at Niagara the use of enriched air was tried in the mixture, and while it gave very good chemical results, the problem of control was so great that we did nothing to put its use into practice. By its use outside energy can be dispensed with, at least to a very large extent, but the problem of distributing a self-combustible gas over a large area of catalyzer will require more experimentation before it is worked out to a certain war-time surety.

Demonstration Plant in New Jersey

Toward the end of July, 1916, the small demonstration plant at the Ammo-Phos Works of the American Cyanamid Co. at Warners, N. J., was put into operation and it fulfilled our expectations in every way. The very light-weight screens first provided proved themselves structurally too weak for continuous heavy service, and we abandoned their use. As a matter of fact, we later increased the weight of our regular screens about 50 per cent purely for structural reasons. We also found that by passing the gas downward through the converter, only a trace of ammonia passed the screen in its original form. It was either burned or decomposed. We also learned that the capacity of a screen could be increased from the 2 lb. of ammonia per sq.ft. per hr., as obtained in our preliminary work, up to 7 lb. of ammonia per sq.ft. of screen per hr., without greatly affecting the efficiency, and under special test conditions we actually succeeded in operating up to 10 lb. of ammonia per sq.ft. of screen per hr. As a steady operating proposition, however, this latter rate would result in a lowering of the efficiency of oxidation 2 or 3 per cent, and we actually figure for most economical operation, with the high cost of ammonia, 5.5 to 6 lb. per sq.ft. of screen per hr. The highest efficiency attained in all of our development work was 96 per cent, but this was under particularly careful operating conditions at a rate of 5 lb. of ammonia per sq.ft. of screen per hour.

Operation of Plant Simple

Operation of the plant was comparatively simple after conditions were standardized. Ammonia gas and air were received at constant pressure and fed through meters and valves for mixing. The control of the mixture was a very simple matter and gave no trouble whatever. The screen attendant would turn on the current to a catalyzer and then feed in the gas mixture at a predetermined rate indicated by an orifice gage on each catalyzer tower. He would then regulate the current so as to obtain the proper temperature, at first measured by pyrometer and later by eye. Two men per shift have operated one hundred catalyzer towers over a considerable period of time, the production of nitric acid during this period averaging one-half ton of 100 per cent equivalent acid per catalyzer per day.

After eliminating the mechanical defects of the early screens we adopted a heavier type, weighing slightly less than 2½ oz. per sq.ft., and we have had some of these screens in service two years continuously on cyanamide-ammonia gas as obtained direct from the autoclave plants and without any purification whatever. These screens seem to be in just as good catalytic condition to-day as when first activated.

Life of the Platinum

The life of the platinum in this process has been the subject of much discussion. Our experience has been that a platinum catalyzer in the ordinary operation of a plant loses between 3 and 5 per cent of its weight per year. Including accidents, it looks as if a screen should give good average service for about one year, at the end of which time it will have lost less than 5 per cent of its weight. It might run longer before being melted, redrawn and rewoven, but we do not have sufficient large-scale experience at our command to give the final answer. In the early days of our experience we had many mechanical accidents and we thought this deterioration of platinum would be considerably greater than the above figures indicate, but on the basis of our experience with the large Government plant, where a very careful check of all platinum was kept, we feel certain at least of the above figures for deterioration and period of renewal. With more skilled operators and higher development of equipment, under conditions more favorable to manufacture than during the war, everything points to a very long life of catalyzer when used on cyanamide-ammonia. Coke-oven ammonia seems to present a different aspect.

Various Criticisms Advanced

Several times during the past year there have appeared in print some rather serious criticisms of ammonia derived from cyanamide, particularly in reference to its content of impurities harmful to the platinum catalyzer, as well as to its general application to oxidation. The first published criticism laid the blame on acetylene. Cyanamide-ammonia as obtained directly from the autoclaves which are producing ammonia gas for fertilizer manufacture does contain a very small fraction of 1 per cent of acetylene gas, but we never found any difficulty in oxidizing such acetylene-ammonia mixtures, provided the acetylene content did not get so high that when mixed with air the resulting gas was self-explosive when conducted to a hot catalyzer. The authors of this first criticism, after rushing into print, later found that their conclusions were entirely in error and that it was not acetylene that was causing the trouble. The true cause then became phosphine. They again rushed into print with a second paper showing the evil influence of this phosphine.

Autoclave gas undoubtedly does contain traces of phosphine at times, but the quantity is so small that present-day quantitative methods are unable to detect it with any degree of precision. Having never used any other but such autoclave gas in our laboratory and hav-

ing no trouble whatever with poisoning of the platinum catalyzer, even with screens in use two years, we did not pay very much attention to the matter at first. However, as the criticism of cyanamide-ammonia became a matter of public discussion we thoroughly investigated the whole subject and learned to our surprise that carefully purified autoclave gas, in which it was freed from acetylene, phosphine and other possible impurities, showed consistently about 10 per cent less efficiency on the same screen as when we used the raw gas.

Investigation Shows Curious Condition

This was a most curious state of affairs, and after we had firmly established this surprising difference under the most careful control possible, we learned that the platinum catalyzer seems to activate itself slowly to each particular and peculiar gas to which it is subjected during activation and that a catalyzer which had been activated on autoclave gas will not work efficiently on purified autoclave gas or on coke-oven ammonia, but requires a wholly new activation. Left to itself the period of readjustment from one form of activation to another is about ten days to two weeks, whereas our critics were subjecting their catalyzer to ten different kinds of gas on the same day and naturally drawing some very erroneous conclusions. We found a gauze activated on coke-oven ammonia could not be used efficiently on cyanamide-ammonia and that one activated on cyanamide-ammonia could not be used efficiently on coke-oven ammonia, on immediate turn-over, and that it took at least ten days of steady operation on the second variety of gas before the efficiency arose to where it was on the kind of gas on which the catalyzer was activated. We then found on examining the catalyzer closely that there were structural differences in the form which the platinum took when activated with different varieties of ammonia gas.

I have here a slide containing a bit of platinum gauze as received from the weaver and also a piece of gauze which has been in service for some time; the difference on direct vision is quite striking. I have here also a piece of the full-sized catalyzer which has been in service for a long time, showing this effect of activation. Some of our most insistent critics, when thoroughly educated by us to these facts, have later asked to be given ammonia gas high in acetylene and phosphine in the hope that through its use their own impossible apparatus could be made to operate to at least somewhere near the efficiency of our type. It has been most harmful to the progress of the development of the oxidation of ammonia in this country that such individuals as were responsible for the publication referred to above ever interested themselves in the subject. The false information spread broadcast will take much honest endeavor to discredit.

Cyanamide Process at Muscle Shoals

I can only add here that the cyanamide process was installed in the Government nitrate plant at Muscle Shoals, Ala., the whole equipment there embracing 700 catalyzers capable of easily producing, with inexperienced attention, about 250 tons of equivalent 100 per cent nitric acid per day, and which could be pushed, under emergencies and demands, to 50 per cent greater output, or 350 to 375 tons per day, without an extreme sacrifice in efficiency. The autoclave plant transformed cyanamide into ammonia at an efficiency of 97 per cent, as measured over an extended test under independent Government control.

In this test the plant was operated by men, part of whom had been trained in the American Cyanamid Co.'s experimental plant, but the chemical control was entirely exercised by Government chemists. The catalyzer efficiency for all catalyzers over this same period of time was 91.5 per cent. The absorption efficiency to the production of nitric acid was 98 per cent. This is equivalent to a total efficiency from cyanamide to nitric acid of 87 per cent, and of ammonia gas to nitric acid of practically 90 per cent. With more experienced operators, undoubtedly these figures would have been raised several per cent in the next six months. The figures are certainly a direct contradiction of a statement of some of our critics that cyanamide-ammonia cannot be oxidized at any high degree of efficiency because of its impurities. As a further matter of interest, the power requirement of the process, as installed, averaged less than 1-7 kw-hr. per lb. of nitric acid made on the catalyzer.

The gases leave the catalyzer at practically redness, although attempts are made to radiate as much heat as possible. They enter flues under the floor and are carried to coolers, where their temperature is brought down to as near normal as possible. They then pass into oxidation chambers, where a minute or two of rest converts practically all of the nitric oxide to nitrogen dioxide. This passes into absorption towers, where oxidation to nitric acid takes place and the acid is absorbed in water. Due to high concentration of nitric oxide gases, the efficiency of recovery in our absorption system is very high. In the Government plant it averaged above 98 per cent and frequently ran for long periods of time at 99 per cent. All absorption was done in water and no soda towers were used in the system whatever. The strength of acid obtained could be run as high as 50 per cent or even more, but as the material was to be used for making ammonium nitrate, no attempts at obtaining extreme concentrations were made. Since this nitric acid is extremely pure, circulation through aluminium pipes is entirely feasible and possible, and its handling with this facility at our disposal was a simple problem.

As to the cyanamide-oxidation process, it does not lend itself as readily to very small-scale installations as the old niter pot, because of the cost of installation, but where ammonia gas is available and it is not necessary to provide separate ammonia equipment, even in this case it will find some very interesting uses. For instance, at the Ammo-Phos Works of the American Cyanamid Co., a catalyzer operating on ammonia gas is supplying nitrogen oxides direct into a sulphuric acid chamber plant with very great success and at very good economy over the old potting process. Not only are the nitrogen oxides much cheaper than when made from nitrate of soda, but the consumption is very much less and the control of the chamber plant very much simplified.

Cost of Oxidation Process Not High

With ammonia gas of suitable quality obtainable at no higher unit price than equivalent nitrogen in nitrate of soda and on a reasonably large operating scale, the oxidation process will make concentrated nitric acid for at least as low a cost as the niter pot and on a large scale at a lower cost. The cost of the plant is somewhat more than for a similar sized pot plant, but

the consumption of raw materials and of labor, and the ease of manipulation, all greatly favor the ammonia oxidation plant, and it is quite likely that where the size of the installation is sufficiently great, it will offer a very serious competitor of the old nitrate of soda process.

On a fair sized plant, the operation, concentration, overhead, taxes, interest and depreciation will amount to approximately one-third of the cost of concentrated nitric acid, but this can only be accepted as a most general figure, because each plant and location must be studied individually, as these factors exert a very considerable influence on the total cost of the product. It must further be remembered that not all varieties of ammonia have shown themselves capable of oxidation. The Muscle Shoals plant furnished some rather interesting data on the cost of nitric acid and ammonium nitrate, the factory cost on the latter being less than one-half of the Government fixed price, from such figures as were obtained during the short period of partial operation of that plant. The cyanamide oxidation process has been fully protected by patents and its development and installation are still wholly in the hands of the American Cyanamid Co.

Conclusion

In conclusion, the early prophecy of Kuhlman is about to be fulfilled, and large consumers of nitric acid will do well to look closely to the oxidation of ammonia in planning their future extensions. As a war-time emergency the development in all the warring countries has given us a direct answer to its practicability. Without it Germany would not have lasted a full year of modern warfare, and the Allies themselves were forced to come to it, even with Chile open to them. When coupled with the fixation processes, its saving in transportation, raw materials, sulphuric acid, and its adaptability to large-scale units places it far ahead of the older nitric acid process, and for certain special applications it has no competitor. It was a long time coming to the front, but I believe it has now reached the point where future extensions and improvements will be rapid, and I anticipate it will soon be producing its better product alongside its older competitor on a fair-sized scale.

Lead Poisoning

THE susceptibility of women workers in lead industries to certain forms of lead poisoning and the dangerous effects of this occupational poison on their children are two important facts brought out in a bulletin on Women in the Lead Industry (Bulletin No. 253) just issued by the Bureau of Labor Statistics of the U. S. Department of Labor. Lead, which is by far the most common industrial poison, is responsible for no less than 95 per cent of all the poisoning due to occupation, according to Teleky, a German authority. In this country lead poisoning is a fairly familiar occurrence, but until comparatively recent times it has not been at all common among women workers because relatively few women have been employed in lead industries. Now, however, women are beginning to enter occupations in which exposure to lead is inevitable, and it is regarded as very important to look carefully into the question of their employment in such occupations and to determine whether it will be better to safeguard them by requiring employers to use every known means to reduce or eliminate the hazard of lead poisoning or by prohibiting the employment of women entirely in those occupations in which lead poisoning constitutes a considerable hazard.

British authorities hold that women are more susceptible to poisoning by lead than men, and legislation in Great Britain has followed these authorities, with the result that women are barred from some of the most dangerous lead work. On the other hand, the Germans believe that the apparently greater susceptibility of women to lead poisoning is to be explained not by their sex, but by the fact that they are usually more poverty-stricken than the men, are undernourished and obliged to do work for their families in addition to their factory work. Observations in the pottery industry in this country seem to bear out the German theory, for while a much larger proportion of women than of men were found suffering from lead poisoning in the East Liverpool and Trenton districts, it was also found that in these districts the men are members of a strong union, are well paid, and have good living conditions, while the women are unorganized, underpaid, poorly housed, poorly fed, and subject to the worry and strain of supporting dependents on low wages. In the unorganized pottery fields, in the tile works, and in the art potteries of the Zanesville district the men and women were in the same economic class, all making low wages, with everything which that implies, and here the rate of lead poisoning was slightly greater among the men.

Whether or not women are more susceptible to lead poisoning than men, the records show that they are more likely to have the nervous form of lead poisoning than are men. Women suffer more from lead convulsions and lead blindness, men from lead paralysis and lead colic.

The report points out that "women who suffer from lead poisoning are more likely to be sterile and to have miscarriages and stillbirths than are women not exposed to lead. If they bear living children these are more likely to die during the first year of life than are the children of women who have never been exposed to lead." Striking proof of this fact is contained in the bulletin. "Everyone will admit that a poison which may destroy or cripple a woman's children is a far more dangerous poison than one which only injures the woman herself. This is why it is necessary to forbid the entrance of women into the more dangerous kinds of lead work and to surround their employment in the less dangerous ones with all possible precautions," says the bulletin.

The bulletin opens with a brief description of lead poisoning, noting some of the well-known symptoms by which it is easily recognized, but calling attention as well to symptoms which are less clear and which prompt the statement that "there is no known poisonous substance which can give rise to such a variety of symptoms as lead." A number of typical cases are briefly described. An important fact brought out in the discussion of lead poisoning is the difference in susceptibility of workers. For example, in one white lead factory the records show that one of the employees began to feel symptoms of lead poisoning at the end of two weeks' time, and died after five and a half months. In the same factory was a man who had worked in clouds of white lead dust for 32 years, ever since he was a boy of 12, and had felt no ill effects.

Flaky Fractures and Their Possible Elimination

A Critical Review of the Literature Bearing Upon Oxides and Other Inclusions in Steel, Together With an Application of the Principles of Physical Chemistry to Conditions in a Steel Melt—Deductions of Technical Importance Are Drawn Which Where Applied Reduced Failures

By HAAKON STYRI

IN CONNECTION with the hypothesis that flakes are largely due to non-metallic inclusions, it is of interest to review in part the previous work of other investigators concerning inclusions and crackings in steel.

Capt. H. G. Howarth,[7] on examining fractures, found inclusions sometimes visible to the naked eye, but often so small that a handglass or microscope had to be used for detection. The color varied from sulphur-yellow to green, or to cream and bronze, and they sometimes covered 10 per cent of the area. They were mostly elongated, but had also irregular shapes. Laminated fracture and a small reduction of area with external cracks in the specimen were associated with them. They were more common in large than in small forgings, which were reduced from 1 to 5, and were mostly found in the bottom end of large ingots, while the streaks were always placed longitudinally. He had not been able to detect a single greenish defect in longitudinal tests. He notes the optical similarity of detached pieces of the slag particles from the fractures to manganese silicate slag.

Stead in discussing the above paper mentioned the reaction between silicon, manganese and oxygen and gave the following analysis of a residue from dissolving steel in dilute HNO_3: SiO_2, 46.6; MnO, 48.08; Al_2O_3, 3.39; FeO, etc., 1.92.

Fay[8] shows that MnS causes a fibrous structure in fractures and gives an example of a 12-in. rifle where this had caused fracture during service in spite of excellent heat treatment.

E. F. Law[9] discusses the different forms of "non-metallic impurities" and advocates the necessity of proving by analysis whether or not silicon and manganese are present as oxides, and gives examples of blister sheets where those with high oxygen have the poorest properties.

J. E. Stead[10] found on welding blowholes and cavities in ingots that for complete welding the surfaces must be in actual contact at a temperature above 950 deg. C. (and preferably at least 1100) and that disruption can be caused by faulty forging. Morgan said in discussion that surfaces or blowholes would not necessarily come in contact during mechanical work: they may only be distorted. Stead remarked later that segregations of S (MnS) may cause premature fracture on transverse test even when blowholes were perfectly welded, and that FeO does not prevent welding in certain cases where sufficient carbon is present, because the oxygen can be consumed in decarbonizing the surrounding material.

Rogers[11] shows the presence and influence of MnS in fractures by means of a gelatine emulsion of silver bromide.

J. N. Kilby[12] gives two causes for "oxides" in steel melting: they are formed during melting and not removed, or they are introduced by excessive or erratic feeding of ore. He advocates having as high as 2 per cent silicon in the total charge from the start, and the using of limestone to reduce the amount of FeO in the slag, thereby increasing the manganese yield. Slag with CaO will act as a better absorbent of extraneous matter existing in steel and thus minimize the oxidation of manganese. When slag is added to the charge it will protect the bath from oxidation. The hearth condition is important in the acid open-hearth process, whether the hearth is saturated with oxides or not. He also gives evidence that teaming at a correct rate is necessary to prevent the ingots from cracking.

McWilliam and Hatfield[13] in a paper on the elimination of silicon in acid open-hearth show how the amount of silicon in steel corresponds in general to the amount of silica in the slag at normal bath temperatures.

Boylston,[14] studying the relative merits of various agents for deoxidation of steel, comes to the conclusion that no startling difference is noticeable in their action.

J. E. Howard,[15] discussing sound steel ingots, mentions the impossibility of welding across inclusions and the consequent defects from rolling them into streaks, forming laminations and causing danger in transverse tests. Petinot, in the discussion, also noted the danger from oxidation products of aluminium and silicon, and says the use of titanium is less dangerous because the TiO_2 formed will help flux the other slag inclusions provided sufficient time is given in the ladle. With less inclusions to contaminate the surface of the pipe, this will be easier to weld. Zimmerschied listed defects in automobile steels, increasing in importance to the last—ingotism, seaminess, pipes, segregates, non-metallic inclusions—while Dudley said segregation is decidedly reduced with ferrotitanium, and is not so marked with silicon.

Hibbard[16] considers the distribution of solid non-metallic impurities in steel to be important; they are dangerous if present as pellicules in the crystal joints even if the total amount is small, and the influence of the impurities is most important during hot work, because they make the steel brittle. He cites a case[17]

where improvement in spring steel was obtained by adding pig iron to the melt and letting it boil, and says that agitation is of little use if the inclusions do not coalesce, for which time must be given. The particles in the bottom of an ingot do not get time to assemble before the freezing of the steel.

Rosenhain,[18] in reviewing the subject of inclusions for the International Congress for Testing Materials, says that the fundamental question of solubility of slags in steel is not solved, and refers to Hibbard's conclusion that inclusions are due to a combination of the purifiers manganese and silicon with oxygen sulphur and to Stead's idea that oxygen is taken up by steel on passage through air in pouring. He proposes attempting to coalesce small globules of slag in a manner related to the glassmakers' practice of introducing a moist potato in the melt to produce large gas bubbles. He also mentions banding in plates as being due to ferrite crystallization on elongated foreign particles and compares this with the persistence of inclusions in ferrite bands in welds.

Stead[19] showed how a coarse network of inclusions persisted after heat treatment which destroyed the primitive ferrite network, while Portevin and Bernard[20] gave an example of a coarse ferrite network containing small holes with consequent brittleness persisting after quenching in water at 850 deg. C. and drawing to 700 deg. C.

Ziegler[21] cites evidence for the idea that inclusions serve as crystallization centers for alpha ferrite.

Stead[22] argued that inclusions alone do not act as crystallization centers for ferrite. Ferrite streaks result rather from an unequal phosphorus distribution during the freezing of the ingot, incidentally associated with inclusions enveloping the primary crystals and worked into streaks by mechanical treatment. Phosphorus can be evenly distributed by prolonged heating above 1200 deg. C. Brearley, in discussing, said that intimate contact must be necessary to induce ferrite crystallization on foreign particles, and Rosenhain remarked that nuclei must be isomorphous to iron to induce such crystallization.

N. J. Belaiew[23] says that the macrostructure of a specimen of steel is a result of nonhomogeneity in chemical composition of crystals solidifying at different points. Therefore it cannot be changed by ordinary treatment—mechanical work will only distort, and temperature, if high enough, will only produce local change within the macrocrystal.

F. Robin[24] believes cracking is mostly due to foreign matter or small cavities, since his experiments showed the most fissure-formation in unclean steel. He also observes that fissures formed in spite of expert forging followed inclusions. By forging nickel steel (Ni 2.5%, Cr 1.5%, C 0.5%) at 1100 deg. C. he produced fissures which did not follow martensite lines.

Portevin and Bernard,[25] in discussing the interrelation between mechanical properties and Widmanstättian structure, show how W-bands and martensite are related, and give in some shock tests an example of poor quality of steel where ferrite is partly left in Widmanstättian structure after forging, and how heat treatment can improve this. Belaiew noted that certain Russian artillery contracts include a paragraph that forgings may be rejected if Widmanstättian structure can be found at a magnification of 50.

G. Charpy[26] describes experiments to show the uneven amount of work the particles in an ingot get in forgings as compared with rolling. He says on test-pieces taken from forgings on transverse planes with different amount of reduction that "there is a dominant reason to forego comparison of such test-pieces owing to the variations in composition and in structure which are inevitable in transverse sections of any ingot." He shows further how the elongation and reduction in area of transverse test-pieces are reduced with an increasing amount of reduction in work when compared with corresponding properties of longitudinal test pieces, and remarks that this difference will increase very much with an increased amount of impurities. Impact tests showed the influence of the direction of the fracture to the direction of the rolling, with the best results where the stress is parallel to the direction of work.

H. M. Howe[27] in discussing dull porcellanic fibrous fractures, remarks that lengthwise banding of ferrite accompanies fibrous fractures and offers itself as their natural cause. Furthermore, they are ultimately due to slag in steel of plastic origin; but in steel from liquid origin are due to dendritic segregations (including carbon, phosphorus, manganese, slag and blowholes) drawn out lengthwise in rolling and forging.

A. McCance[28] estimates that fully 90 per cent of the failures he has noticed are due to nonmetallic inclusions. Steel which is heat-treated to brittleness starts cracking from such inclusions, but this effect is negligible in steels with proper heat treatment, although inclusions in groups are detrimental. He calls attention to Inglis' work[29] showing that stresses existing in metal surrounding holes are not equally distributed, but are greatest at the end of the axis, which is normal to the direction of pull. Proximate calculation shows that small particles cannot rise to the surface in the time given for ingot solidification. Viscosity of the steel is also an important factor, and therefore he advocates a high tapping temperature. Brinell, Hachney and Stead believe that different amounts of manganese are necessary to take care of the sulphur in steel, while Röhl[30] notes that MnS is insoluble in steel; consequently McCance says it is unlikely that FeS is not completely reduced by manganese.

Steinberg,[31] however, shows that artificial inclusions of sulphides in steels will distribute equally on freezing from the liquid and grow smaller on quenching from high temperature, therefore some sulphur must go into solution even before fusion. McCance also gives an experiment on Al_2S_3 artificially placed in steel, which shows some reaction, since the steel was welded across the sulphide inclusion.

McCance further states that there is a relation between the heats of formation of the oxides and the degree to which they can be reduced, and quotes Levy's[32] experiment, placing slag ($2MnOSiO_2$) in contact for 30

min. with siliceous cast iron, with the result that manganese increased in the iron, and SiO_2 increased in the slag $\frac{1}{3}$ to $\frac{1}{2}$ in quantity. Slag in contact with steel and the inclusions will ultimately be converted into manganese silicate. The loss of manganese in acid open-hearth practice is due to a reduction of FeO by manganese. He emphasizes the influence of slag constitution and temperature on the ease of elimination of impurities, giving an example of how greater fluidity improves the steel. (He apparently means, however, that boiling in the bath will cause slag particles to mix into the steel, for the same reason that steel globules are found in the slag, but only the latter occurrence can be normal, since boiling gives an upward movement of gas bubbles.) He says further that oxidation of carbon can only take place when silicon and manganese have been reduced to traces, while the solubility of FeO in steel must be independent of outside pressure, in spite of his reference to Baraduc-Muller,[33] that CO (and hydrogen) are given off under reduced pressure.

The many authors cited above do not use the term "flake"; but it is evident to the student that the causes of failures in the steels which they have investigated are often similar to those which have caused flaky fractures of steels described in the first portion of this paper. In this experimental work the author has come to the conclusion that the predominant cause for flakes is nonmetallic inclusions, which will be the more dangerous the larger the area they present at right angles to the direction of stress and the sharper they cut.

Flakes may also be caused by incipient cracks formed through faulty pouring, heating or forging, which by the way, are more easily formed when inclusions are present. In general, the high elastic limit and tensile strength in rejected testbars indicate that inclusions and incipient cracks ordinarily are only spots from which the irregularity in the fracture (flakes) propagates during testing. Blowholes and segregation may occasionally cause flakes.

Since no distinct microstructure has been found associated with flakes, the heat treatment generally given to commercial steel will not cause flakes, nor can it eliminate them; but proper heat treatment will of course improve the physical qualities of the sound portions of flaky steel and lessen the tendency to crack formation.

With the principal causes for flakes and corresponding failures identified it will now be proper to discuss the factors that will influence their elimination.

Equilibrium of Oxides in Iron

We know from the many researches on inclusions that they are oxides, silicates and sulphides. They are probably in general not inclusions of the same composition as the furnace or ladle slag. Sulphides are sometimes identified and in exceptional cases, when quantitative analysis can be made, the difference in composition is shown as in the above stated by Stead and in another, furnished the author by party F, which gives SiO 41.8, Fe_2O_3 1.8, Al_2O_3 17.15, MnO 29.3, CaO 0.5, MgO 0.54, with the ordinary slag SiO_2 51.4, Fe_2O_3 22.2, MnO 19.9, CaO 3.1. For many cases, examined in the first part of this paper, different kinds of particles were found in the same fracture.

Inclusions may have been caused mechanically in tapping a pouring, but ordinarily inherent conditions in the molten steel is the cause. A very good idea of the formation of the inclusions may be had if we utilize in part H. Le Chatelier's admirable treatise on the application of pure science to metallurgy,[34] a work which is hardly known in English literature. Le Chatelier arrived at the basic principle for the reduction of oxides by applying the dissociation law. Thus the partial pressure of oxygen as it varies with the temperature can be calculated by means of Carnot-Clapeyron's formula applying to simple reactions:

$$(1) \qquad -\frac{L}{T} + 0.002 \ln P = 0.032$$

where L is the heat of the reaction, T the absolute temperature, and P the dissociation pressure. Thus at 1600 deg. C. we have for the dissociation of iron oxide

$$(2) \qquad 2FeO = 2Fe + O_2 - 130 \text{ cal.}$$

Substituting in equation (1)

$$-\frac{-130}{1873} + 0.002 \ln P = 0.032 \qquad \text{whence}$$

$$\ln P = -18.7 \qquad \text{or} \qquad \log. P = -8$$

$$P = 10^{-8}$$

which as noted above is the partial pressure of the oxygen in c.g.s. units for free iron oxide at 1600 deg. C. In a saturated solution of iron oxide in steel at 1600 deg. C., with a hypothetical cover of FeO and where equilibrium exists, the partial pressure of the oxygen in solution must be equal to the dissociation pressure of free iron oxide at the same temperature. If less oxygen than corresponding to saturation is dissolved in the steel, some more FeO from the slag will go in solution. Utilizing the law of mass action, one can find the partial pressure of the oxygen at concentration less than saturation, when there is no slag cover, thus:

Equation:	$2FeO$	$\leftrightarrows$	$2Fe$	$+$	O_2
Concentrations:	a		b		p

$$(3) \qquad \frac{a^2}{b^2 p} = \frac{1}{k} \text{ where } k \text{ is a constant.}$$

b may be considered equal to 1, since the concentration of iron varies but little, then

$$(4) \qquad p = ka^2$$

and at saturation

$$(5) \qquad P = kA^2$$

Le Chatelier gives the solubility of FeO in steel at 1600 deg C. as 1.1 per cent (equivalent to 0.244 per cent O), while P has been already calculated to be 10^{-8} Dividing (4) by (5)

$$\frac{p}{P} = \frac{a^2}{A^2}$$

Substituting known values and letting the concentration of FeO represent the concentration of O since it makes no difference mathematically and facilitates the following calculation:

$$(6) \qquad p = \frac{10^{-8}}{0.244^2} a^2$$

From this equation the partial pressure of different concentrations of oxygen in steel can be calculated. If the metal is in contact with a slag of another composition than pure FeO, which is the condition assumed in deriving the above equation, the equilibrium would demand less amount of oxygen in the steel (less oxygen pressure) even disregarding the influence of the heat of reaction between FeO and other components of the slag, because of the lower concentration of FeO in the slag, and it should be possible in practice to arrive at the oxygen pressure at equilibrium, at least numerically,

[33] *Carnegie Scholarship Memoirs*, 1914, p. 216.

[34] *Revue de Metallurgie*, 1912; "La Silice," p. 558.

by analyzing for oxygen in steel and the corresponding slag of ferrous or complex silicates. Pickard[35] and Schirmer Kichline[36] therefore do not give the maximum solubility of oxygen in steel, when they state 0.092 per cent O present, but possibly the equilibrium for their particular slags, of which analyses were not given.

To find the influence of an addition of manganese to the bath at 1600 deg. C. we will further with Le Chatelier consider the equation

$$2MnO = 2Mn + O_2 - 182 \text{ cal.}$$

Conc. c d e

Substituting in equation (1) and solving,

$$E = 10^{-14}$$

which is the dissociation pressure for free manganese oxide.

By the law of mass action

$$\frac{c^2}{d^2 e} = \frac{1}{k_1} \tag{7}$$

In equation (7) d, the concentration of manganese in the steel under a manganiferous slag, can be varied and c, the concentration of MnO in the slag, can be considered maintained constantly equal to unity. Hence

$$e = \frac{k_1}{d^2} \tag{8}$$

In case there is no iron in the metal, that is, for pure manganese, $d = 1$; equation (8) further simplifies into

$$E = k_1 \tag{9}$$

$$e = \frac{10^{-14}}{d^2} \tag{10}$$

That is to say, the dissociation pressure of manganese oxide in the steel, or in other words the partial pressure of O dissolved, varies inversely as the square of the concentration of manganese in the steel.

It is now easy to show graphically how manganese and oxygen will influence one another when dissolved in steel. For this purpose Curve I in the accompanying

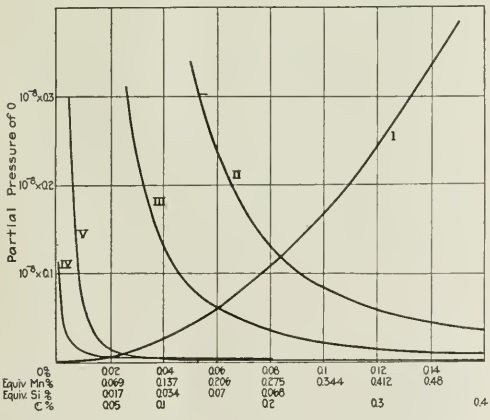

chart has been calculated by the author after formula (6), giving the oxygen pressure for different concentrations of O in steel, and Curve II after formula (10) for the partial pressure of the oxygen which can be in equilibrium with different concentrations of manganese in steel. (The abcissæ give the manganese equivalent of oxygen to facilitate graphic calculation; equal horizontal lengths will give the amount of manganese necessary for the reduction of oxygen.)

If we change the concentration of MnO in the slag and disregard the influence of the heat of reaction between MnO and other components, we can see from equation (7) that the oxygen pressure and accordingly the concentration of oxygen must decrease with the square of the concentration of MnO in the slag for equilibrium. Curve III is therefore calculated for 50 molecular per cent MnO in the slag.

For silicon a similar calculation may be made to that for manganese, noting that the heat of the reaction at 1600 deg. C. is 180 cal. The result is

$$h = \frac{10^{-13.7}}{g} \tag{11}$$

where h is the dissociation pressure (or partial pressure of oxygen) of silica and g is the concentration of silicon in the steel, and the two are inversely proportional to each other. Curve IV is calculated for the partial pressure of oxygen in the bath which is in equilibrium with varying amounts of silicon, and as before the silicon equivalent of oxygen is noted on the horizontal axis.

Further, consider the equation at 1600 deg. C.

$$FeO + C = Fe + CO - 36 \text{ cal.}$$

Concentrations: i j m n

By equation (1)

$$n = 10^{2.78} = 600 \text{ atmospheres}$$

the pressure of CO in equilibrium with FeO, carbon and iron.

Generally when iron oxide is reduced by carbon CO_2 will be found simultaneously with CO in amounts varying little with the temperature at about $\frac{1}{3}$ the total. The solubility of carbon in steel at 1600 deg. C. is given by Le Chatalier at approximately 5.5 per cent, and of oxygen 0.244 per cent, and both can be present simultaneously at this concentration if the total gas pressure ($CO + CO_2$) is 870 atmospheres. Substituting these values in the mass-action equation, and letting m equal unity

$$K_3 = \frac{ij}{mn} = \frac{0.244 \times 5.5}{600}$$

For the total gas pressure $CO + CO_2 = 1$ atmosphere, the partial pressure of CO is equal to 0.7 atmosphere, and we can calculate the concentration of oxygen and the corresponding oxygen pressure of the CO in steel for different amounts of carbon, as represented by Curve V, since the oxygen-pressure of CO and of FeO must be equal at equilibrium. The abscissæ in this case are chosen to make the amounts of carbon most commonly found in the bath come within the limits of the chart. If the gases CO and CO_2 should need a higher pressure than 1 atmosphere to escape from the bath, the ordinates of Curve V would be correspondingly higher. On the other hand, if we introduce another gas in the steel, for instance, by poling, we facilitate the formation of CO and CO_2 since they do not then alone carry the whole atmospheric pressure + the hydrostatic pressure of the steel above.

Practical Deductions From the Curves

The chart tells clearly that manganese alone is a comparatively weak deoxidizer, but has a much stronger action if some other deoxidizer like silicon is present. This for the reason that the MnO formed will then combine with the SiO_2 formed simultaneously, thus re-

[35] *Carnegie Scholarship Memoirs*, 1916, p. 74.

[36] *Trans.*, American Institute of Mining Engineers, 1913, p. 436.

ducing the concentration of both MnO and SiO_2 in the slag, whereby in turn the deoxidizing power of the metals is increased. There is the further advantage of adding manganese and silicon to the bath together, since the resulting slag will be more fluid and it can more easily combine into larger drops and rise to the surface. Any other addition of deoxidizer which forms an oxide which will combine to a more fluid slag will be of advantage.

We see further from the chart that carbon is a stronger deoxidizer than manganese, and weaker than silicon for low concentrations but stronger at higher concentrations. The numerical values of the chart must of course be considered with reserve since so little experimental work has been done along this line. This will explain why silicon under certain conditions can be reduced back into the bath.

The chart represents only the conditions at 1600 deg. C. To calculate for other temperatures, one would have to know the corresponding solubilities of oxygen and carbon. In general, we know from the formula given above that the dissociation pressures of the metallic oxides increase with temperature and also from v. Juptner's calculations[37] that the dissociation of CO changes little with temperature.

It is easy now to understand how the strong reducing power of carbon can be utilized to advantage in refining steel. In the melting-down period when the temperature is low, oxygen will principally combine with silicon and manganese to form small slag globuli in the bath. After the bath is liquid, as the temperature increases the oxygen pressure of these oxides will increase, with the result that carbon will gradually get a stronger reducing action on them. CO will be formed and the bath commence to boil, with the consequence that the small gas bubbles drive the nonreduced slag particles with them up through the steel just like drops of rain take dust particles out of the air. For this reason boiling must be considered the best method of purifying steel, and more so in nickel than in carbon-steel, since the viscosity of the former is higher, and therefore the slag particles included will have the more difficulty in liquating and rising to the surface. It is wrong to "kill" the boil by introducing the ordinary deoxidizers manganese and silicon, because the very oxides are then formed which we want to eliminate. On the other hand, boiling should not continue until the carbon gets too low, with the result that oxygen would be taken from the slag (which in open-hearth practice is always to some extent oxidizing), necessitating in turn the addition of more deoxidizer to properly kill the steel before tapping if time cannot be given to deoxidize with wash metal. Boiling should be diminished toward the end so that only the amount of alloys should be added which is necessary to prevent gas-evolution upon solidfication. If no deoxidizers are added the gradual concentration of carbon and oxygen toward the center of the ingot during the solidification period would otherwise cause such gas-evolution.

Oxidation products are not the only foreign impurities in steel. They also come from the slag and from small particles in spouts, runners, ladles and molds, which should all be kept strictly clean. Other sources, much worse, have come to the author's notice; for instance, the throw of lime with the stream of steel in the ladle in order to get a thick slag cover.

[37] *Journal*, Iron and Steel Institute, 1907, p. 59.

Only few words need to be said about the other main impurity in steel—sulphur—since the reactions between it and iron, manganese and aluminium are exactly similar to the reactions between oxygen and iron, manganese and silicon. But for the lack of some experimental data a chart like the one given here could be calculated for sulphur, and it would show how desulphurization (sulphur pressure) would depend on the heat of reaction of the sulphides. It is incorrect to say that MnS is insoluble in steel. MnS will dissolve until the "solubility product" of manganese and sulphur prevents further solution, a point which of course is different in solid and liquid steel. The same holds true for Al_2S_3, explaining how McCance found Al_2S_3 distributed in steel after forging.

Casting Practice

Casting of the steel was treated to some extent in the first part of this paper. A little may be added about the desirability of letting the ingot freeze after the onion or after the landlocking-type, and about the further treatment of the ingot. The slow cooling which produces the onion-type will tend to push the impurities towards the center, increasing also the segregation of phosphorus and carbon. H. M. Howe prefers freezing after the landlocking-type, casting the steel at low temperature in a cold mold. In that case the inclusions will be interlocked within the columnar structure and will be more evenly distributed. Thus the segregation will be less, but fewer particles will get time to rise and "slag off."

The columnar or landlocking structure will be deepest and most pronounced in the bottom part of the ingot because the mold is thickest there, and coldest when the pouring starts and it is found that the bottom end of the ingots gives more failures from flaky test-pieces than the top end. The author, for this reason, would prefer freezing after the onion-type, using hot molds or sand molds.

Columnar surface structure is weaker against strain in a tangential direction arising when the inner layers of the ingot pass the critical range. To prevent failure at this time it would be advisable to strip the ingot as soon as possible and put it in a soaking pit, thus equalizing the temperature before the outer layer has passed the critical. The depth of the columnar structure, which depends on the heat gradient in cooling, will probably influence the tendency to crack, and it will therefore be important to be able to calculate beforehand the temperature gradients for different sizes of ingots, molds and temperatures. Some trials in this direction have shown the author that the time-temperature curves for any point will be expressed by a series of exponential functions and probably too cumbersome to apply. Fletcher[38] has made approximate calculations for the same purpose, not considering, however, the heat conductivity.

The ingot should preferably be forged direct from the soaking pit. If it must be cooled down, it should be done in the pit or in ashes, while subsequent reheating must be done very carefully so that the inside does not crack or is left too cold for the subsequent works, which will then easily start interior cracks. With proper heating, forging is better done between V-dies than between flat dies, since the angle of flaw in the material then will change when the piece is turned and forged in the new position.

[38] *Engineering*, 1918, p. 342.

The principal cause for flakes, which generally are found associated with low physical test values, was found to be nonmetallic inclusions. In making the steel, therefore, the greatest care should be taken to eliminate such inclusions as much as possible by a properly conducted boil which should die down without the addition of deoxidizers, when the steel is nearing the correct carbon content. When the oxygen present in the steel is reduced to the least practicable amount by the carbon (or added wash metal), and in good time before tapping, deoxidizers should be added only in sufficient quantity to prevent gas evolution ("rising") when the steel is poured—manganese and similar alloys of course in quantities wanted for physical properties.

Likewise much care should be taken that inclusions from other sources are not introduced, particularly when tapping and pouring.

It is theoretically and practically impossible to get a steel absolutely free from nonmetallic inclusions; the endeavor must be toward eliminating them as much as possible technically. Blowholes and strong local segregations should not be present in steel which is properly made.

The subsequent treatment of the steel in pouring, heating and forging is further of great importance, because cracking may start when strains set in from uneven heating or cooling, particularly dangerous at the period of critical contraction or expansion; or when strains are produced by improper forging.

Due to the fact that the inclusions present are most dangerous when the stress is applied at right angles to their largest section, it will be best to have as little reduction done as practicable so that the inclusions will retain the spherical form as nearly as possible when the forgings will be subjected to transverse stress.

Heat treatment can never eliminate inclusions and therefore never entirely prevent the formation of flakes; but a proper heat treatment which brings the steel surrounding the slag particles in the best condition to resist the propagation of cracks on straining the material will naturally improve the service qualities of such steel. Repeating the heat treatment and taking new test bars until good tests are found is unsafe for the same reason if flakes are once found in a steel. A bar taken from a nearby place may give a poor result, since the distribution of foreign particles or cracks is never even. It must be considered better practice to take tests from the forging before it is machined, and reject the piece entirely if fractures of test bars show flakes with nonmetallic inclusions when examined with the binocular microscope.

Carnegie Institute of Technology,
Pittsburgh, Pa.

Request for Quotation on Borax

Four thousand pounds of borax, of a grade suitable for use for the killing of flies, are required by the War Department. Prices on this material are desired f.o.b. place of storage or production and f.o.b. Camp Jackson, S. C. Bids will be received until 10 a.m., April 22, 1919, and must include: Discount for cash in ten days, delivery, description of containers and packing, approximate shipping cubage and weight, specifications that will be fullfilled by the material. Address reply to: Paints Branch of Raw Materials Division, Attention of Capt. A. O. Van Suetendael, Munitions Building, Washington, D. C.

Metal Strapping on Wooden Boxes

One of the quickest and cheapest methods of adding to the strength of a wooden box is to wrap it with thin, flat metal straps. The ability of a box to withstand the hazards of transportation may thus be increased several hundred per cent. Tests made at the Forest Products Laboratory for the War Department have provided some information as to how a box should be strapped to add most to its durability.

The best place to apply the strap is apparently about $\frac{1}{4}$ of the length of the box from the end. The strapping is preferably nailed at each edge of the box to hold it in place, having, of course, been drawn snug by special tools for that purpose. Nailing the strap in place works well on boxes made of lumber $\frac{3}{8}$ inch or more in thickness, but cannot be successfully used on thinner material because the nail splits the board. On thin boxes it is necessary to join the two ends of the strap (for which purpose there are several devices), thus making a metal band around the box held in place by tension.

Depending on tension alone to keep the strap in place is, however, open to one serious objection. Unless the box is constructed of dry lumber, shrinkage reduces its circumference to such an extent that the metal strap is no longer tight. This action not only reduces the effectiveness of the strap, but commonly permits it to slip over the end of the box. A shrinkage in moisture content of 10 per cent will permit the straps to fall off when the boxes are subjected to the ordinary hazards of transportation. A shrinkage of 5 per cent will loosen the straps considerably, but the shrinkage is rarely enough to permit them to fall off.

The effect of shrinkage of the box is also serious when the straps are nailed at any point, since it causes them to buckle or "festoon." The reinforcing effect of the straps is thus diminished and the box becomes dangerous to handle. It is important, therefore, that metal-strapped boxes which are to be in transit or storage for any length of time should be built of dry lumber.

Recovery of Waste Paraffined Paper

In the process of manufacturing paraffined paper and various products such as cartons, cups and wrappers, large quantities of impregnated paper stock are now wasted. In the making of paraffined paper alone, it is estimated, the daily waste amounts to 8 or 10 tons.

An opportunity for the recovery of a large part of such waste paper and impregnating material is offered in the application of a method recently developed at the Forest Products Laboratory, providing mill trials are as successful as the semi-commercial laboratory work indicates.

The recovery method consists in treating the finely shredded waste with petroleum oil solvent in a series of extractions, which removes practically all the paraffine. The paraffine is afterward separated from the solvent, which is used again. The solvent left clinging to the extracted paper is also recovered by a steaming process.

A paper fully as strong as the original can be made from the remaining pulp.

Bituminous Roofing Materials and Construction—II

Description of the Types of Bituminous Roofing: Built-up Felt Pitch, Rubber Roofing and Felt Base Shingles—Comparative Tests for Roofing Materials for Thickness, Tensile Strength, Absorption of Moisture, Pliability, Volatility and Fillers—Specifications

By George Landis Wilson

SATURATED felts are used for what are known as "built-up" roofs; that is, roofs that are constructed or "built up" of the roof deck to fit the building. Such roofs when surfaced with gravel or crushed stone are popularly known under the generic term of "gravel roofs." The terms 5-ply, 4-ply and 3-ply refer to and correctly describe the number of layers of saturated felt which cover the entire roof area.

When gravel roofs are applied on a concrete roof deck the standard practice is to coat the concrete with pitch and apply a complete coating of pitch over each layer of felt; when applied over a wooden roof deck, the first coating of pitch is applied over the second layer of felt and a coating of pitch provided with each succeeding layer of felt.

Gravel roofs are not generally adapted for roof inclines exceeding 2 in. fall to the foot horizontal, and an incline of from ¼ to ½ in. to the foot is better than an incline exceeding ½ in., for the reason that it makes more practical the use of the maximum permissible amount of pitch and gravel on the surface, and as the "built-up" method using saturated felt and pitch provides a surface that is watertight or will hold water, instead of being capable of simply shedding water, there are many practical reasons in favor of the roof deck having a minimum incline.

Pitch Coatings Must Be Uniform and Complete

In "built-up" roofs the fundamental principle involved is that the coatings of pitch shall be uniform and complete, for the reason that a coating of pitch that covers only 90 or 95 per cent of a given area is of no value in preventing leaks in the other 10 per cent or 5 per cent of the area, and the roof covering would, practically speaking, be serviceable for just as long a time if such an incomplete coating were omitted altogether. On an average 25 lb. of pitch is required for coating each 100 sq.ft. between the felt layers; and 75 lb. is required for the surface coating into which the surfacing of gravel is embedded.

Felts saturated with coal tar, and pitch obtained by the distillation of coal tar, are the materials which have been most generally and widely used for constructing "built-up" roofs, and are the materials on which the reputation of gravel roofs has been established. There are almost numberless instances where such roofs have given watertight service for upward of 20 years without repairs, and many instances of a life of 30 and even 40 years. A limited amount of open-minded investigation will produce proof of these statements. What has been done can be done again. Tarred felt and coal-tar pitch, at least the equal in quality of materials produced in former years, are available and contractors capable of skillful handling of these materials are also available to any one who will pay the price. Other saturants and other pitches from various sources are sometimes substituted for or offered as superior in quality to coal-tar pitch for use in gravel roofs. None has thus far shown any special merit or proven the equal of the materials originally used.

The gravel surface has three important functions: It permits the use of 75 lb. of pitch to the square (100 sq.ft.) on the surface by preventing the pitch from flowing to the low points of the roof—if gravel were not used a paint coat of pitch is all that would be prac-

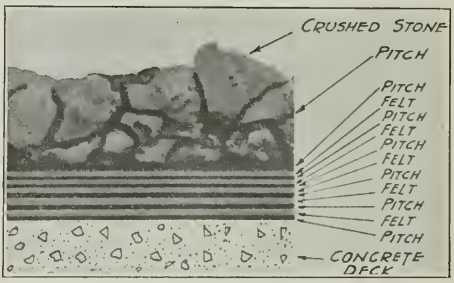

FIG. 1. GRAVEL ROOF APPLIED ON CONCRETE DECK. ILLUSTRATION ACTUAL SIZE

tical; it makes the roof fire-retardant (rated as Class "A" by the Underwriters' Laboratories); it protects the waterproofing material from wear and tear of the elements and more particularly from abuse, both necessary and unnecessary, to which most flat roofs are subjected. Crushed slag or any crushed rock may be used instead of gravel if it does not, like soft limestone, for example, disintegrate rapidly on exposure, or does not, as is the case with trap rock, crush into sharply angular particles. The standard practice is to require that the gravel or crushed stone be from ¼ to ⅝ in. in size, and while slight variation from this range may be permissible, there are practical reasons for complying as nearly as possible with the standard.

Prepared Roofings

Prepared bituminous roofings are of two general classes: (*a*) those composed of a single layer of felt of various thicknesses; (*b*) those composed of two or more layers of felt or other fabric cemented together with bitumen. The multiple layer prepared roofings are designated as 2-ply, 3-ply, etc., by counting the layers of felt or fabric that are stuck together, what-

ever their thickness or whether they happen to contribute to the element of waterproofing or not. The single layer roofings can be subdivided into two general classes: "smooth surfaced," i.e., those on which the bituminous coating forms the wearing surface, and "mineral surfaced," i.e., those having granular material in the form of crushed slate, feldspar, etc., or natural gravel or pebbles forming the wearing surface. The "smooth surfaced" roofings are generally made in three weights standardized at 35, 45 and 55 lb., and through an unfortunate trade practice known as 1-ply, 2-ply and 3-ply, respectively. The industry is endeavoring to correct this misnomer and recently voted unanimously in favor of designating the three weights as, "light," "medium" and "heavy." The "smooth surfaced" variety is sometimes referred to as "skin-coat" roofing, because the saturated felt is coated with bitumen, while the multiple layer roofings do not generally have a coated surface. They are also known as "rubber" roofing, because they feel something like and have an appearance similar to rubber. The term "rubber" has been used to such an extent as to have practically become generic, as applying to roofing composed of a single layer of felt saturated with bitumen and coated with bitumen without a surface of granular material.

"Rubber" Roofing

The "rubber" roofings of each weight are produced in all sorts of qualities. Each manufacturer has his own ideas regarding the maximum to which he is willing to go in producing a serviceable article, whatever the cost. Likewise, each has his own idea about the minimum for which he is willing to stand sponsor in the effort to meet price competition. Most manufacturers produce four or more varieties under different trade names or brands, the price range between the maximum and minimum being roughly as 10 to 6. All "rubber" roofings have a finely ground soapstone or talc brushed over the surface to prevent sticking in the roll. This gives the roofing a light colored appearance when unrolled which is often retained for a considerable period. In order to provide a different appearance for the different qualities manufacturers use powdered soapstone of different degrees of fineness and sometimes a very fine sand, and also endeavor to control the size of the corrugations in the coated surface or pass the roofing through smoothing rolls after coating the surface, to remove the corrugations altogether. There is no standard practice in this endeavor to have the different grades of roofing distinctive in appearance, each manufacturer adopting whatever practice seems best suited to his particular line.

Mineral surfaced roofings are generally made on the same base as is used for 2-ply "rubber" roofing, and when a mineral surface is applied the other side of the felt is usually left uncoated. Crushed slate, either red or green, has during recent years become the most popular mineral surface. Apparently, crushed slate has some inherent merit that is not present in other forms of granular material, the most plausible reason advanced being that slate crushes into less angular particles than feldspar, quartz or other stone, and more completely covers the bitumen into which it is embedded. Another reason for the popularity of the slate surface is the color, and as this is natural in the slate it does not fade. The standard weight of slate surfaced roofing is 80 to 85 lb. to the square.

Practically all prepared roofings are put up in rolls sufficient to cover 100 sq.ft. (known in the roofing trade as a square) allowing for whatever lap is recommended in the directions enclosed in the roll. A 2-in. lap is usually recommended, and in laying roofing with a 2-in. lap 108 sq.ft. of fabric is required to cover 100 sq.ft. of surface.

Felt Base Shingles

The use of crushed red or green slate as a surfacing material for prepared roofing and the cutting of that roofing into shingles were the first development in the felt base roofing industry toward providing a roof covering having any artistic merit, the shingles in particular giving relief to the objectionable flat effect and conforming to the popular idea of what a roof surface should be like, inherited by reason of use for generations of wooden shingles and slate. The serviceability of the material used in a single layer has long been established, and the popularity of slate surfaced asphalt shingles has caused them to fill a long felt want in almost every community where roofing with artistic merit and at the same time fire retardant and of moderate cost was desired. They are dependable for use on practically every structure the roof surface of which has an incline in excess of 4 in. to the foot.

Slate surfaced shingles are generally furnished in size 8 x 12⅔ in. laid 4 in. to the weather, thereby providing triple protection; or in strip form, four shingles to the strip, 10 in. wide laid 4 in. to the weather and providing double protection.

Prepared roofing and shingles are sold under trade mark brands. Most manufacturers have been wise enough to maintain the quality in the several brands they have established. As is the case with cigars, new

brands of prepared roofing are coming out all of the time to replace old brands which are run out, and for about the same reasons.

Comparative Roofing Material Tests

It is with some misgiving that the following tests are offered as a guide in buying roofing, but they are simple and, therefore, available to practically every buyer at a minimum of trouble and expense. It should, however, be kept in mind that there is no united opinion in the industry as to the value attached to any one of the tests; that there are no agreed maxima or minima, and that one piece of roofing might be distinctly sub-

standard when compared with another, if judged by one of the tests, and yet be a much better article.

Therefore, if one test is to be made use of in judging the comparative value of a piece of roofing, most of the other tests should also be made, for the reason that thickness may be obtained by use of inert mineral filler; tensile strength obtained at the expense of pliability; pliability by the use of soft saturant or coating readily volatile, etc. The tests are useful only as a basis for comparison. A succession of tests will show uniformity, or the lack of it. Uniformity is at least indicative of care in manufacturing processes.

Thickness: This is readily determined by the use of a micrometer registering thousandths of an inch and having a face at least a half inch in diameter. Mineral surfacings other than soapstone should be carefully scraped off before measurement is taken.

Tensile Strength: Specimens should be cut lengthwise from the middle of the sheet 5 x 1¼ in. reduced to 1 in. wide for a distance of about 2 in. at the center. The ends of a specimen must be held in clamps which swing freely so as to avoid unfair tearing strain. Tests are usually made at a temperature of 77 deg. F. Ten breaking tests are averaged.

Absorption of Moistures: Tests should be started with pieces 18 in. square and due to freshly cut edges more readily absorbing water they should be trimmed 3 in. all around before re-weighing, making allowance for the reduced area when comparing weights. Immerse in soft water at 77 deg. F., for 100 hr., or suspend in atmosphere artificially saturated with moisture. Weight before and after tests indicates degree of thoroughness of saturation and waterproofing quality.

Pliability: Strips 1 in. wide cut lengthwise from center of sheet bent under water. Bend the sample around a series of cylinders ½, 1, 1½, 2 and 2½ cm. in diameter (approximately $\frac{3}{16}$ to 1 in.) in exactly two seconds time. The absence or presence of cracks on the surface, or deeper cracks when bent over the smaller size cylinders, furnish the comparison.

Volatility: Tests at high temperatures are of little value. Exposure of samples hung edgewise to dry heat of maximum summer temperature, and careful comparison of weight before and after will disclose fugitive solvents and tendency to become brittle. If comparison of same samples before and after drying show marked increase in tensile strength it suggests lack of permanent waterproofing quality.

Inert Mineral Filler: Remove all mineral surfacing material, record the net weight of sample, burn it completely and weigh the ash. Dry felt contains from 6 to 10 per cent, by weight, of ash, and the dry felt weighs approximately one-fourth as much as the finished roofing without mineral surfacing. More than 3 per cent, by weight, of ash recovered on burning sample of roofing indicates use of inert mineral filler, either in dry felt, saturant or coating.

Building Specifications

It is only fair to note that as a rule purchasing agents and architects make their drawings and specifications which relate to roof decks, roof faces, joinings, flashings and connections so incomplete, indefinite or general that the owner is dependent almost entirely upon the skill and good faith of the roofing contractor and his employees for serviceable roof protection. When an effort is made to draw a drum-tight specification the result is frequently an unworkable instruction. In the absence of competent and complete inspection a rigid specification serves only to eliminate the conscientious bidder and insure the presence on the job of adventurers, willing to take any chances.

In the purchase of roofing this condition of indefiniteness, when recognized at all, is offset by the guarantee. The guarantee is a form of abuse which has survived longer than 50 years from the early days of the industry when bitumen roofs were experiments offered to replace unsatisfactory metal roofs. No guarantee ever yet kept water out of a building. At its very best the guarantee merely secures repairs, after the roof has leaked, without direct charge. It never covers consequential damages to the interior of the building or its contents. The existence of the guarantee never serves to deter the irresponsible adventurers from taking chances. On the other hand, it frequently serves him as self-justification for producing a roof calculated to a nicety to just "get by." The architect or engineer who permits this does not serve his client faithfully.

It is impossible to cover fully within the limits of an article like this all of the problems which grow out of the endless combinations that may be produced from this assortment of bitumens, gums, solvents, thinners, fibers, fillers, weight-makers and adulterants. The mere mention of some of them causes the observer of ordinary intelligence accurately to visualize their probable value for roofing purposes, or the lack of utility which they represent in the hands of any so ignorant or unscrupulous as to use some of them. Aside from labor, fuel, equipment and plant supplies, probably 90 per cent of the industry represents the utilization of what is, or until within recent years was, commercial or domestic waste materials. This fact has been unfairly made the excuse for turning out roofing materials which are deficient in tensile strength, ductility, durability and weatherproofing qualities. Those are the requirements which measure the utility of roofing faces in terms of service to the ultimate consumer. Success in this business is in direct proportion to the delivery of such service.

General Conclusions

Other things being equal, bituminous roofs are serviceable in direct proportion to the quantity of bitumen uniformly contained in each square foot of the covering.

Felt, and mineral surface if used, must be ample in quantity to permanently hold waterproofing material.

Joinings, flashings and connections require for their construction real skill, based upon experience, otherwise they surely cause trouble, however good the roofing material may be.

In general coal tar pitch makes the most satisfactory flat roofs, while asphalt from various sources is more readily adaptable for steep roofs, but each must be properly combined with suitable felts.

Flat roofs should be flat, the more nearly level and providing some drainage the better; while steep roofs should be steep, not less than 4 in. fall to the foot. A fall of 5 to 6 in. to the foot is best in latitudes where there is ice and snow.

Roofing of relatively temporary nature is justifiable only on buildings known to be temporary, but during that predetermined temporary period it must be quite as tight as any other roof.

Recent Chemical and Metallurgical Patents

Canadian Patents

Extracting Iodine and Other Chemical Products From Seaweed by Dry Distillation.—Iodine or like products are extracted from seaweed by dry distillation in a closed retort. The gases are passed through a condenser and the uncondensed gases are passed through a metal salt which will absorb the volatile iodine and bromine. The residue of the retort is soaked with water and the dissolved salts are separated. (Canadian Patent No. 187,721, J. A. W. BREDENBERG.)

Refining of Volatile Metals.—The metal to be refined is fed in an electric-arc furnace through a liquid trap formed by said metal, so as to maintain a metal bath in the furnace bottom, the surface of the bath is exposed to heat from the arc and the metal vapors are removed and condensed. (Canadian Patent No. 187,864, S. HULDT.)

Alumina Purification.—The impure alumina resulting from the calcining of alunite and the leaching of the calcine is mixed in a finely divided condition with water to form a pulp, and the resulting pulp is subjected to a flotation operation with the addition of an agent promoting the flotation of the alumina, and thereby separating the alumina in the form of a froth from the impurities and recovering the alumina from the froth. (Canadian Patent No. 188,441, J. W. HORNSEY, assigned to the Minerals Products Corp. of New York, Jan. 28, 1919.)

White Gold, a Substitute for Platinium.—The process of manufacturing white gold consists of fusing fine gold, pure nickel and pure zinc and mixing them thoroughly while in fusion. The proportions of the components are: Gold 75 to 85 per cent, nickel 10 to 18 per cent, and zinc 2 to 9 per cent. (DAVIS BELAIS, Canadian Patent No. 188,628.)

English Patents

Distilling Zinc.—To obtain the maximum amount of zinc in zinc distilling processes, the zinc dust deposited in the condenser is subjected to a rubbing action and to compression by means of a screw mounted to rotate in the bottom of a condenser. The zinc dust is forced by the screw to the condenser outlet and into a receptacle of molten zinc. The amount of compression and the duration of the pressure may be adjusted by varying the pitch of the screw and the extent to which the screw enters the opening. (English Patent No. 120,549—1918. E. S. BERGLUND. Not yet accepted. Jan. 8, 1919.)

Production of Ammonium Sulphate and Alumina.—Clay, bauxite and other natural substance containing aluminium with iron and silica acid is treated with sulphuric acid to yield an impure solution of aluminium sulphate. The solution is treated with a reducing agent such as sulphurous acid or a sulphite to reduce ferric to ferrous sulphate, and is mixed while at 70 to 100 deg. C. with ammonium sulphate, allowed to settle at this temperature, and the decanted solution is cooled to separate crystals of ammonium alum. The crystals are decomposed by exposing them to ammonia, either gaseous or in solution, to yield ammonium sulphate and aluminium hydroxide, which may be heated to obtain alumina. (English Patent No. 120,550—1918. J. P. A. LARSON and W. D. BERGMAN, both of Stockholm, Sweden. Not yet accepted. Jan. 8, 1919.)

Platinized Asbestos as a Catalytic Agent.—Platinized asbestos for use as a catalyst is prepared by dissolving platinum in aqua regia, evaporating the solution to dryness, extracting the residue with hydrochloric acid, neutralizing the solution with soda, mixing it with a paste of asbestos and distilled water, and reducing at 60 deg. C. by formic acid. The product is finally washed, dried, carded and made into flakes. (English Patent No. 120,551—1918. E. FRABETTI, Rome, Italy. Not yet accepted. Jan. 8, 1919.)

Thorium Compounds.—Solutions containing thorium obtained, for instance, by dissolving in water the product of the action of sulphuric acid or monazite sand are treated with oxidizing agents such as potassium or sodium permanganate or hydrogen peroxide in the presence of acid. Hydrated thorium oxide or peroxide is precipitated and may be dissolved directly in nitric acid or other acid, and the resulting solution may be crystallized. The thorium nitrate may be purified by precipitation by the oxidizing agent first employed, or the solution may be treated with sodium carbonate in excess, which dissolves the thorium carbonate first produced. The solution is filtered and treated with caustic soda to precipitate thorium hydroxide, which is then dissolved in nitric acid. (J. V. and W. A. CLARKE, London, England. English Patent No. 120,748—1918. Jan. 15, 1919.)

Malleableizing Cast Iron.—Iron castings to be malleableized are heated in the presence of Mond blast-furnace, or like gas, containing carbon dioxide and hydrogen. Sufficient carbon monoxide is preferably present to prevent excessive decomposition of the carbon dioxide by the hydrogen. Sulphur and hydrocarbons are preferably removed from the gas before use. The temperature of treatment is 700 to 800 deg. C. for black-heart castings, and 800 to 950 deg. C. for white-heart castings. (English Patent No. 21,074—1918. F. PERRY and INDUSTRIAL INVENTIONS, LTD., Tipton Staffordshire, Eng., Jan. 29, 1919.)

Lead Arsenate. — Lead arsenate is produced by thoroughly mixing, preferably by rubbing or grinding, lead carbonate or white lead with arsenic acid in the presence of water. A concentrated solution of arsenic acid may be used, and water may be added at the end of the reaction to produce a paste of the desired consistency. (English Patent No. 121,101—1918. J. LYTLE, Dunbyon, Formby, Eng., Jan. 29, 1919.)

Preservative Coating of Metal Surface.—A preservative coating is formed on metallic articles by dipping the article into an oil, for example, a mixture of whale oil and mineral oil, draining and then heating to a temperature high enough to gasify the volatile constituents in an oven, which permits the escape of the lighter gases. A suitable oven is one having an outlet at the top, the aperture of which can be varied, and a suitable temperature is about 300 deg. C. (English Patent No. 121,150—1918. N. C. F. JENSEN, Southall, Middlesex, Eng., Jan. 29, 1919.)

Vom Baur Electric Furnace

By C. H. Vom Baur

VERY soon after electric furnaces in the iron and steel industry were placed in commercial operation in the United States, some eleven years ago, it became evident that one of the limits of their possibilities depended on the life of the refractories. All kinds and types of electric furnaces have to take care of this item much more than any open-hearth furnace. The experience of many electric furnace operators and designers has been along these lines. The simplest refractories of any arc furnace are those of the single phase, single electrode type, with a bottom electrode, when this has a round hearth and the carbon electrode at its center. (See Fig. 1).

It is evident that the heat at the inner contour of the side walls and of the slag line of this furnace is the same at any point thereof. Consequently when the side walls

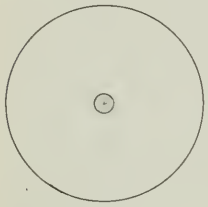

Fig. 1

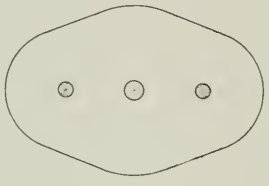

Fig. 2

burn away they do so equally. That is to say, there are no hot spots on any portion of the side walls or slag line, due to the heat of the arc, and manifestly no portions of the refractories need repairs when properly laid, prior to some other portion. As the single phase furnace of any but the smallest sizes is not popular with central station managers, it is seldom seen today in the newer installations, polyphase furnaces having almost exclusively taken their place.

At first, on account of the many advantages of the polyphase furnace, compared to the single phase, the refractory feature as above mentioned did not receive the attention it deserved until the appearance of the Vom Baur electric furnace, which has with its three electrodes, 3-phase 2-wire, the same good heat distribution as the simple single-phase furnace, as shown in Fig. 1. This good heat distribution in this furnace is accomplished by the combination of placing three electrodes in a straight line, and very nearly knowing the electrical heat, at least close enough for all practical purposes, which emanates from any of these electrodes after the bath is in the molten state, or nearly so. The contour of the inner refractories can easily be ascertained so as to give a curve to the refractories which is correct, so that the heat at the slag line, at the side walls and at the hearth banks is the same, thus assuring among others the equal burning away of all the refractories involved. Only very small allowances from the theoretical have to be made in order to accomplish this purpose. The shape as given to these furnaces is shown in Fig. 2.

Fig. 2 shows a well defined minor axis drawn through the middle electrode, and this shape is the natural result of the radiated heat reaching points on the minor axis from the three electrodes. Theoretically, the center electrode would have 41 per cent more heat than either of the end electrodes, but it is not possible to reach this condition practically and maintain the arcs at their best setting. The current at the central electrode is therefore diminished by several per cent and the extreme points in Fig. 2 are brought slightly together. Even so, the heat from the central arc is fully one-third more on an average than from either of the end arcs, and consequently in order to keep the refractories at their proper distances the metal bath has a larger surface than the furnace would have if each of the electrodes ever gave off an equal amount of heat. With basic operation the advantage is that the metal presents a greater slag area for the same tonnage. As the rate of refining depends not only on the chemical composition of the slag and the heat at the point of contact between the metal and the slag, but also on the amount of surface engaged between the slag and the metal, it follows that the rate of refining is quicker.

There is very little poking to be done when melting down cold scrap, as there are no hot or cold spots on the side walls or near the doors. The quick melting down with this furnace, as with all others, depends mostly on the amount of transformer capacity which the furnace has. However, as this furnace has an even heat distribution at the side wall refractories, it is more efficient than the other furnaces which lack this feature.

Special attention has been given to the doors, which have watercooled frames, fit very snugly, yet allowing

FIG. 3. DISCHARGE OF 6-TON FURANCE AT THE HERCULES STEEL CASTING CO. PLANT

for all expansion, and can be tightened after they are closed by giving two handles a few turns.

Structurally, the furnace is very strong, having a rounded and cone-shaped bottom connected with the upper shell, which is a series of curves. This sets on two rocker arms and the whole is tilted by means of connecting rods from suitable geared mechanism in such a way that when the furnace has reached its maximum tilting position, if the operating motor should continue to run for any reason, the furnace goes back to its normal position nevertheless. The tilting mechanism also allows the furnace to tilt slightly backward some 6 deg. and 7 deg., so that the slag can be taken off this door instead of from the spout. Both doors are used for charging.

The center of gravity of the furnace is low, as the heavy parts of the standards are no higher than is needed for the full travel of the arm holding the electrodes, and as these have an upward tilt the upright standards are still further shortened. For carrying the copper cables a much lighter structure is used, all of which can be seen from the photographic reproductions.

Either carbon or graphite electrodes can be used and changed quickly; either hand or automatic electrode control is furnished. The oval shape and turtle-back construction of the roof makes a very strong construction, standard brick being used throughout for the roof construction, excepting a few special electrode brick. The electrical connections are the simplest possible, being merely three sets of cables from the transformers to the electrodes, and no complication on the high tension side. Electrically the furnace conditions are satisfactory to the central station managers, the power factor being around 90 per cent and the phases not being distorted more than with other arc furnaces. After continued operation it has been observed that the furnace does not bulge at all, this being another indication of the even heat distribution as mentioned.

The furnace is equally well adapted for melting down miscellaneous steel scrap for castings on either acid or basic bottom, selected scrap for quality and tool steels, or for melting down cast iron borings, or the like, or for use with malleable iron. The furnace is made in sizes from ¼ ton up to 30-ton sizes and for any electrical condition. The first of these furnaces in this country of 6-ton size has been placed in operation at the works of the Hercules Steel Casting Co., Milwaukee, Wis. Others are being installed both here and abroad, and the patents for France, Belgium, Italy, Switzerland, and Spain have been disposed of to Le Flaive & Co. of St. Etienne, France.

Personal

Mr. Oliver U. Bradley is U. S. oil and gas inspector for the Department of the Interior at Muskogee, Okla., with offices in the Federal Building.

Mr. W. J. Cotton, formerly chemical examiner for the United States Civil Service Commission, has joined the staff of the Color Investigation Laboratory of the Bureau of Chemistry, Washington, D. C.

Mr. Courtenay DeKalb recently sailed for Spain to investigate the metallurgical and mining resources of that country for the Department of Commerce.

Mr. J. H. Deppeler of the Metal & Thermit Corp. has been elected a director of the American Welding Society.

Mr. Henry B. Faber, head of the school of pyrotechnics, Columbia University, was recently tendered a dinner and presented with a loving cup by the staff of the school. Mr. Faber has also been appointed associate in the department of chemical engineering at Columbia University.

Lieut. Russel C. Gebert, recently released from the Ordnance Department of the Army, has been made chief metallurgist and superintendent of heat-treating at the Hammond Steel Co., Syracuse, N. Y.

Dr. Federico Giolitti is to be awarded the Bessemer medal of 1919 by the Iron and Steel Institute of Great Britain at its meeting on May 8.

Mr. Samuel M. Green, president of the Samuel M. Green Co., Inc., Springfield, Mass., has become a director of the Norwalk Iron Works, South Norwalk, Conn.

Prof. H. E. T. Haultain of the mining department of the University of Toronto is in charge of the Vocational Training Branch of the Department of Soldiers' Civil Re-establishment under Mr. W. E. Segsworth, a mining engineer of Toronto, who is in charge.

Capt. C. A. Jennings has received his discharge from the Construction Division, Utilities Branch, of the Army, and has returned to the technical staff of Wallace & Tiernan Co., Inc., to resume charge of the Chicago office. Captain Jennings' work in the Army covered the supervision, operation and maintenance of water purification and sewage treatment plants in various camps.

Mr. W. A. Maxwell, formerly superintendent of the open-hearth department of the Homestead Works, Carnegie Steel Co., has resigned to become assistant general superintendent of the Cambria Steel Co., Johnstown, Pa.

Dr. William C. Moore, for the past five and a half years research chemist for the Cleveland plant of the National Carbon Co., Inc., has resigned in order to take charge of the physical chemical research in the department of immunology in the school of public health and hygiene recently established by the Rockefeller Foundation at Johns Hopkins University, Baltimore, Md.

Prof. Albert Sauveur of Harvard University has returned to Cambridge, Mass., from France, where he had charge of the section of metallurgy in the technical division of the United States air service.

Mr. C. C. Wallace, formerly manager of loading of munitions section of the Stenotype Co., Indianapolis, Ind., is now director of development and service of the Powdered Coal Engineering & Equipment Co. of Chicago.

Capt. A. U. Wetherbee, who recently received his discharge from the Chemical Warfare Branch of the service and who was formerly chief engineer and assistant works manager of the Niagara Alkali Co., has accepted a position as chief engineer with the Powdered Coal Engineering & Equipment Co. of Chicago.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, April 26.—The non-ferrous market has hitherto been uncertain but is expected to follow the conditions created by the iron and steel activity due to lowered prices.

Aluminium:—Conditions are unusually quiet, as aluminium has not declined. Ingots 98-99 per cent, 29-31c. lb. Sheets 18 gage and heavier, 42c. Powder, 0.70-1.40 lb.

Copper:—The market remains quiet with prices standing at 15¾ to 15½c.

Copper sheets, hot-rolled	lb.	$0 22½—	.....
Copper sheets, cold rolled	lb.	.23½—	.....
Copper bottoms	lb.	.30½—	.....
Copper rods	lb.	.19½—	.....
Copper wire	lb.	.17½—	$0.18
High brass wire and sheets	lb.	.18½—	.....
High brass rods	lb.	.17½—	.....
Low brass wire and sheets	lb.	.18½—	.....
Low brass rods	lb.	.21½—	.....
Brazed brass tubing	lb.	.29½—	.....
Brazed bronze tubing	lb.	.33½—	.....
Seamless copper tubing	lb.	.28 —	.....
Seamless bronze tubing	lb.	.29½—	.....
Seamless brass tubing	lb.	.30 —	.....
Bronze (gold) powder	lb.	1.00 —	.....

Antimony:—Wholesale lots are offered from 6¾ @ 7c. and jobbing at 7¼c. The market has a brighter outlook.

Lead:—Prices have declined to 4.75c. per lb. in East St. Louis and 4.975c. per lb. in New York. Sheet lead, 7¾ @ 8c. per lb.

Tin:—The 72½ price fixed by the committee continues and buyers are reluctant, knowing that a considerable decline will come eventually.

Zinc:—Future quotations at East St. Louis are rising: May, $122.50; June, $123.50; July, $124.50; August, $125, and September, $126 per ton. New York spot is $121.50. Zinc dust, 14c.; sheet zinc, 11c. per lb.

OTHER METALS

Bismuth	lb.	$3.20 —	$3.65
Cadmium	lb.	1.40 —	.....
Cobalt	lb.	2.50 —	3.50
Magnesium	lb.	1.75 —	2.10
Mercury	75 lb.	75.00 —	.....
Nickel	lb.	.40 —	.45
Tungsten	lb.	Nominal	
Iridium	oz.	175.00 —	.....
Palladium	oz.	115.00 —	120.00
Platinum	oz.	99.00 —	100.00
Silver	oz.	1.01⅛ —	.....

The Iron and Steel Market

By the middle of April it became generally recognized that the Industrial Board plan for handling the steel market had failed. The popular version was, of course, that the plan failed because the Railroad Administration refused to "co-operate." Scarcely any thought was given to a similar refusal on the part of the Navy Department. Sentiment was not lacking. The Railroad Administration is unpopular, while the Navy Department is an institution of which Americans are proud.

The steel trade was quick to accept as final the apparent failure of the Industrial Board to secure the results it had expected. The steel industry did not seek the Industrial Board for the purpose of suggesting that if a few dollars a ton stood in the way of Railroad Administration endorsement of the plan the barrier might perhaps be removed. For this ready adoption of the idea that the plan had failed there was another reason, which from its nature is not dilated upon, and that is the absolute refusal of the Department of Justice to endorse the plan. The department would not give approval, in advance, of a plan announced to operate for the remainder of the year when there was a possibility that matters might so shape themselves that it would in essence represent an agreement for the maintenance of prices. It was that feature of the whole arrangement that had appealed to the steel industry in the first place. Orders for a few hundred thousand tons of rails, with perhaps a few tens of thousands of freight cars and a few thousand locomotives, represented merely a detail. The important feature promised was that the sellers of steel could assure the public that there was no occasion to wait, that no lower prices could be expected at any time this year. Even at best, however, there was a weak spot in the argument, for the investor in a construction job would not weigh merely the respective advantages of building now or six months hence, but also the advantages respectively of building this year or next year, or even the year after.

The steel trade was as quick to assert that the Industrial Board plan was a failure and that an open market for steel products would follow as it was slow in taking any steps to establish an open market. That steel prices would eventually decline from the level established March 21 has been generally predicted or admitted, but the time of the decline has been altogether in doubt. The break may occur any day, or may be delayed until next June, possibly even longer.

Steel Organization Appears Intact

The organization of the steel trade appears to remain intact, this organization consisting merely in a mutual understanding that what is good for one is good for all and what is good for all is good for one. On account, however, of the very unequal distribution of old orders, upon which, rather than upon fresh bookings, the steel mills are chiefly operating, some producers may easily conclude that their best course lies in cutting prices even though a market decline would be disadvantageous to others. In the price maintenance operation of 1908 the circumstances were altogether different, as it was then contrived that all producers should operate at substantially the same rate. At the present time operating rates are widely divergent.

The philosophy of the steel trade is that inasmuch as light operation involves heavy overhead and therefore relatively high cost, prices should be maintained as well as the thing can be done, until it is reasonably certain that reducing prices will fill the mills, giving a lower production cost and at the same time enabling the market to start upon an advance. No matter what the price level may be, when mills begin to fall behind in deliveries advances begin. Given such a condition, it matters relatively little to what level prices may temporarily fall, as they can quickly recover, but if prices fall without full operation being produced the tendency is for them to decline farther. For instance, a mill operating at 65 per cent can well afford to take additional business at particularly low prices in order to raise the operating rate to 85 per cent, as the cost of production of the entire output will be reduced. Steel prices, therefore, will decline when producers feel there is large business to be secured. Thus far they have not displayed a hopeful frame of mind.

Steel mill operations, which averaged 87 per cent of capacity in January and 77 per cent in March, declined to a rate of not over about 60 per cent in the closing days of April. Even that is not an altogether bad rate, if maintained uniformly throughout the industry, but some small plants were closed entirely while some large independents operated at not over 45 per cent. Most of the Steel Corporation subsidiaries operated at 70 per cent or more, the Steel Corporation having apparently picked its orders, long ago, in anticipation of some such situation as this.

Pig Iron Independent of Steel, Marketwise

Marketwise, pig iron has shown its entire independence of steel. The merchant furnaces gave but lukewarm assent to the Industrial Board plan when first proposed, and when the Industrial Board prices were announced March 21 they expressed their disapproval of the price structure very plainly, as they felt that steel was reduced altogether too little in proportion to pig iron. The pig-iron market had been an open one until the Government took charge as a war-time measure, and the furnaces had no objection to a return to that condition. Accordingly they stated to all interested that there would be an open market in pig iron. It was not that the furnaces desired prices to decline, but that they desired, through actual experiment, to ascertain where prices would go if left to themselves. The individual furnace could then determine whether or not to blow out, awaiting either higher prices or lower production cost or both. The experiment, however, has been rather unsatisfactory thus far, the reaction being very sluggish. In other words, while merchant furnaces are willing to cut prices few opportunities, by way of inquiries of any size developing, have been afforded, and in most districts the March 21 prices still obtain, nominally at least.

The Chemical Market

New York, April 25.

Coal-Tar Products: — Considerable improvement is noted in this situation, particularly in the way of heavy crudes. A number of the items have been in demand in a liberal way for the past month or more, and it is not exaggerating to state that more material has been sold during the past month or six weeks than for six months previous to this time. Benzol in particular has felt the effects of the increased demand. As a result prices have advanced from 10 to 15 per cent during the past two months. It is also encouraging to producers to note that buyers are contracting over longer periods, as well as buying in large quantities. The other crudes are also more active and prices in most cases have advanced. Naphthalene, however, is an exception; although material is moving much more freely, prices are easy.

Phenol:—The demand has improved and large quantities

are moving. While prices are slightly firmer and higher, they are not greatly changed. This is due to the fact that large quantities are available.

Benzol:—A decided improvement is noted. Buyers are closing for large quantities both spot and contract. During the past week prospective buyers have experienced difficulty in securing spot material, which is so unusual that it is a matter of discussion in the trade.

Naphthalene: — Buyers are closing for large quantities. Although the demand is hardly as brisk as it was when the industry was booming, there is some improvement. The fact that large quantities of material are available tends to keep prices at low levels.

Toluol: — The volume of business closed is quite heavy in the aggregate, but the demand is mostly for moderate quantities. Tank car lots are not moving to any extent, but nevertheless prices are stiffer.

Aniline Oil:—While there appeared to be a firmer undertone to this market for a time, prices were lowered in most instances by second hands shading producers' prices.

Benzaldehyde:—The production is heavier than formerly, with the demand only fair, and prices are easier as a result.

Paramidophenol:—The production has increased of late, but the demand is quite regular and prices are unchanged.

Orthotoluidine:—Buyers are operating on a conservative basis, the production has increased, and prices while quotably unchanged are shadable in most instances.

H Acid: — Most of the business passing is for small quantities, material is plentiful and prices are lower.

Phthalic Anhydride:—There are some large factors competing in this situation and prices have been slashed in some instances in an endeavor to line up business.

Xylol: — The demand is only routine and prices, while quotably unchanged, are little less than nominal under the circumstances.

Paratoluidine: — Consumers are limiting their purchases to small quantities, with prices somewhat lower.

HEAVY CHEMICALS: — While there has been no resumption of important activities in the heavy chemical market, the past few weeks have shown more interest from buyers and producers are expecting a resumption of activities in the near future. A better inquiry for export material was noted which resulted in some improvement in trading in general in this direction and handlers of this business state the outlook for an increasing business is promising. The large tonnage used by the Government for the shipping of food supplies is easing up from week to week and the matter of space is in consequence more encouraging. Local trading is still confined to small-lot transactions, but consumers' stocks of many of the items seem to have become depleted and a slight improvement on the whole is noted.

Soda Ash:—Although there has been nothing in the way of any important trading reported, that is for material over the balance of the year, consumers appear more frequently in the market but are still confining their purchasing to immediate needs; however, this activity seems sufficient to keep the market for bag material firm. Bags from the warehouse were offered by second hands at from $1.55 to $1.60 while barrels were available at $1.70 to $1.75. No movement was noted in any direction, for double bags which were held at 2c. Middle West, with prices on a parity on the Pacific coast.

Caustic Soda:—The market for this material continues in a very weak position with the resale operators in control of the situation. An effort on the part of manufacturers to meet this condition has resulted in price declines among second hands and offerings were made as low as $2.50 ex-store, with other directions holding at $2.60 to $2.65. Manufacturers toward the latter part of the week were quoting $2.80 f.a.s. and intimated on a firm bid this price might be shaded.

Bleaching Powder:—Trading, for the most part, is direct, but the lack of demand has again had its effect on the market with manufacturers offering large export drums at 2c. f.a.s., while domestic drums were quoted at $1.40 to $1.50 works.

Chlorate of Potash: — There has been a fairly steady business passing for this commodity for export purposes, but the present rate of absorbing material is having no effect on stocks; however, trading is of sufficient volume to take the slack off the market. Prices for the domestic product are firmly maintained at 35c. to 36c. while the Japanese variety is offered at 29c. and 30c.

Sodium Sulphide: — A better demand was noted during the past week for this material and several important sales were reported which resulted in a firming up of the situation. The 60-62 fusel is now held in most instances at 4½c. with the 30-32 crystals being quoted at $1.90 to $2.

Sodium Formate:—Comparatively little is heard of this item in the general market; however, producers report a steady business passing, particularly for the crude material, which is subject to a fair demand. This item is held at from 25c. to 28c. according to quantity, with the crystals held at 35c., although some business has been closed below this figure.

Calcium Carbide:—No new developments have set in to indicate any firming up in this market, with sales noted at below 5c. However 5¼c. to 5½c. is generally asked for material crated for export.

Bichromate of Soda:—The lack of demand is having its effect in this market, with prices steadily declining for resale material. Manufacturers, however, are striving to hold the market at a level of about 10c. ex-store, but resale offerings were made at from 9c. to 9½c.

Bichromate of Potash: — While there has been no resumption of any important activities for this material, there seems to be sufficient business passing to keep the spot situation well sold up. Prices are quotably unchanged at from 34c. to 35c. f.a.s.

Cream of Tartar:—While the item has been neglected for quite a period, a fair volume of export trading has developed during the past week, which resulted in an advance in prices, from 55c. to 75c., with some now holding as high as 59c.

Potash Chrome Alum:—Available supplies of this product are only in limited quantities and in scattered lots. Spot material is generally held at from 19c. to 20c., while that for shipment about the middle of May is held at 18½c.

Chicago, April 25.

Conditions in the chemical market in Chicago continue very unsatisfactory in that quotations on the entire line of heavy chemicals and coal tar products mean very little. Large stocks on hand and a production in excess of sales have produced a condition whereby a buyer with cash can make purchases below the market and in many cases below actual cost of production. An example is caustic soda, on which the mill cost is $2.50 and market quotation $3.25. Cash buyers would have no difficulty in securing carload lots at $2.40. Carbolic acid can be had by merely paying for the container. These items are, of course, of exceptional weakness.

Consistently falling markets of the past few weeks have confirmed regular consumers in hand-to-mouth habits. Concerns normally anticipating in their purchases thirty days are now content to secure a week's supply, saying that the less they buy the more money they save, as next week they are sure to get lower prices.

Indications are, however, that this condition is nearing an end. Mercury has recently advanced and vegetable oils all show a tendency to be firmer in price; some items of this line are actually up ¼ to ½c. Soya bean oil, particularly, is in good demand. The announced policy of the Government to dispose of additional chemical stores in such manner as to least disturb the market is having a good effect.

FLOTATION OILS.—Prices are firm and sales very satisfactory. The annual spring clean-up, which was almost neglected last year on account of the war, has tended to strengthen the turpentine market, all other items in the line being affected to a certain degree.

NAVAL STORES.—Naval stores have been rather uncertain for some time, but with a gradual let-up of labor shortage in the producing fields and a continuance of consumption, conditions are very satisfactory. Sales for April are ranging 60 per cent in excess of those for last month. The market can be said to have certain indications of a downward tendency, or rather of an "evening up" tendency, with no great reductions to be expected.

Imports and Exports

The Department of Commerce reports the following imports and exports for February, 1919:

IMPORTS (TOTALS) AND EXPORTS (BY COUNTRIES) OF GLYCERINE

Nitric, 42 deg.	lb.	.07½	—	08
Oxalic, crystals	lb.	.26	—	.28
Phosphoric, Ortho, 50 per cent. solution	lb.	.07½	—	.10
Picric	lb.	.50	—	.60
Pyrogallic, resublimed	lb.	2.70	—	3.20
Sulphuric, 60 deg tank cars	ton	12 00	—	13.00
Sulphuric, 60 deg. drums	ton	17.00	—	.....
Sulphuric, 60 deg. carboys	ton	20.00	—	.....
Sulphuric, 66 deg. tank cars	ton	17.00	—	20 00
Sulphuric, 66 deg. drums	ton	21.00	—	.....
Sulphuric, 66 deg., carboys	ton	25.00	—	
Sulphuric, fuming, 20 per cent. (oleum) tank cars	ton	22 00	—	25 00
Sulphuric, fuming, 20 per cent. (oleum) drums	ton	25.00	—	.....
Sulphuric, fuming, 20 per cent. (oleum) carboys	ton	30.00	—	.....
Tannic, U. S. P.	lb.	1 40	—	1.50
Tannic, (tech.)	lb.	.60	—	.....
Tartaric, crystals	lb.	.88	—	.89
Tungstic, per lb. of WO_3	lb.	1 60	—	1 75
Alcohol, Amyl	gal.	4 85	—	4 90
Alcohol, Methyl	gal.	1 28	—	1.30
Alum, ammonia lump	lb.	.04½	—	.05½
Alum, potash lump	lb.	.18½	—	.19
Alum, chrome lump	lb.	.17½	—	.18
Aluminium sulphate, commercial	lb.	.01½	—	.02½
Aluminium sulphate, iron free	lb.	.02½	—	.03½
Aqua ammonia, 26 deg., carboys	lb.	.06½	—	.09
Ammonia, anhydrous	lb.	.30	—	.35
Ammonium carbonate, powder	lb.	.13½	—	
Ammonium chloride, granular (white) sal ammoniac	lb.	.12	—	.13
Ammonium chloride, granular (gray) sal ammoniac	lb.	.14	—	.16
Ammonium nitrate		.16	—	.17
Ammonium sulphate	lb.	04 90	—	04 95
Amyl acetate	gal.	3 50	—	3 75
Arsenic, oxide, lumps	lb.	.09	—	.09½
Arsenic, sulphate, powdered	lb.	.30	—	.32
Barium chloride	ton	70 00	—	80 00
Barium dioxide (peroxide)	lb.	.22	—	
Barium nitrate	lb.	.10	—	.11
Barium sulphate (precip.) (blanc fixe)	lb.	.03½	—	.04
Bleaching powder, (see calcium hypochlorite)			—	
Blue Vitriol (see copper sulphate)	lb.	.08	—	.....
Borax, (see sodium borate)			—	.....
Brimstone, (see sulphur, roll)			—	.....
Bromine	lb.	.55	—	.60
Calcium acetate	lb.	.04	—	.05
Calcium carbide	lb.	.05½	—	.06
Calcium chloride, fused, lump	ton	19 00	—	21 00
Calcium chloride, granulated	lb.	.02½	—	
Calcium hypochlorite, (bleaching powder)	cwt.	1 40	—	2 00
Calcium phosphate-monobasic	lb.	.22	—	23
Calcium peroxide	lb.	1.50	—	1 70
Calcium sulphate, precipitate	lb.	.09	—	.09½
Carbon bisulphide	lb.	.07	—	.08
Carbon tetrachloride, drums	lb.	.14	—	.15
Carbonyl chloride (phosgene)	lb.	.75	—	1 00
Caustic potash, (see potassium hydroxide)	lb.	.42	—	.....
Caustic soda, (see sodium hydroxide)			—	.....
Chlorine, gas, liquid-cylinders, (100 lb.)	lb.	.08	—	.10
Cobalt oxide	lb.	1 60	—	1.65
Copperas (see iron sulphate)			—	.....
Copper carbonate, green precipitate	lb.	.28	—	.31
Copper cyanide	lb.	.65	—	.70
Copper sulphate, crystals	lb.	.07	—	.07½
Cream of tartar, (see potassium bitartrate)	lb.	.58	—	.59
Epsom salt, (see magnesium sulphate)			—	.....
Formaldehyde, 40 per cent	lb.	.22	—	.22½
Glauber's salt (see sodium sulphate)			—	.....
Glycerine	lb.	.16½	—	.17
Iodine, resublimed	lb.	4 25	—	4 30
Iron oxide, red	lb.	.06	—	.08
Iron sulphate (copperas)	lb.	.01½	—	.02½
Lead acetate, normal	lb.	.12½	—	.14
Lead arsenate (paste)	lb.	.15	—	.18
Lead nitrate, cyrstals	lb.	.85	—	.86
Litharge	lb.	.09½	—	.10½
Lithium carbonate	lb.	1 50	—	
Magnesium carbonate, technical	lb.	.15	—	.16
Magnesium, sulphate	100 lb.	2.25	—	2.35
Nickel salt, double	lb.	.14	—	.13
Nickel salt, single	lb.	.16	—	.15
Phosgene (see carbonyl chloride)			—	.....
Phosphorus, red	lb.	.75	—	.80
Phosphorus, yellow	lb.	.35	—	.40
Potassium bichromate	lb.	.34	—	.35
Potassium, bitartrate, (cream of Tartar)	lb.	.58	—	.59
Potassium bromide, granular	lb.	1.25	—	1.26
Potassium carbonate, U. S. P.	lb.	.17	—	.18
Potassium carbonate, crude	lb.	.14	—	.....
Potassium chlorate, crystals	lb.	.35	—	.40
Potassium cyanide, 98-99 per cent	lb.	Nominal		
Potassium, hydroxide, (caustic potash)	lb.	.42	—	.45
Potassium iodide	lb.	3 50	—	3 55
Potassium nitrate	lb.	.20	—	.22½
Potassium permanganate	lb.	.60	—	.75
Potassium prussiate, red	lb.	.85	—	.95
Potassium prussiate, yellow	lb.	.45	—	.55
Potassium sulphate	ton	Nominal		
Rochelle salts (see sodium potas. tartrate)			—	.....
Salammoniac, (see ammonium chloride)	lb.	.14	—	.16
Sal soda (see sodium carbonate)			—	.....
Salt cake (see sodium bisulphate)			—	.....
Silver cyanide	oz.			
Silver nitrate	oz.	.63½	—	.65½
Soda ash, light	100 lb.	1 50	—	1 55
Soda ash, dense	100 lb.	2.45	—	3.00
Sodium acetate	lb.	.07	—	.07½
Sodium bicarbonate	100 lb.	2 35	—	2 50
Sodium bichromate	lb.	.09	—	10
Sodium bisulphate, (salt cake)	ton	12 00	—	14 00
Sodium, bisulphite	lb.	05	—	.07
Sodium, borate, (borax)	lb.	.07½	—	.07¾
Sodium, carbonate (sal soda)	100 lb.	1.60	—	2.00
Sodium chlorate	lb.	16	—	.18
Sodium cyanide	lb.	.30	—	.31
Sodium fluoride	lb.	14	—	.15
Sodium hydroxide, (caustic soda)	100 lb.	2.50	—	2.65
Sodium molybdate	lb.	2.50	—	.....
Sodium nitrate	100 lb.	4.07½	—	.....
Sodium nitrite	lb.	.13	—	.14
Sodium peroxide, powdered	lb.	.25	—	.30
Sodium phosphate, dibasic	lb.	.03¾	—	.03¾
Sodium potassium tartrate (rochelle salts)	lb.	.43	—	.43½
Sodium prussiate, yellow	lb.	.18	—	.22½
Sodium silicate, solution (40 deg.)	lb.	.02½-.03	—	.04½-.05
Sodium silicate, solution, (60 deg.)	lb.	.03¾	—	.04¼
Sodium sulphate, crystals, (Glauber's salts)	lb.	.01½	—	.02
Sodium sulphide, crystal, 60-62 per cent, (cone)	lb.	.04½	—	.05
Sodium sulphite, crystals	lb.	.05¾	—	.06½
Strontium nitrate, crystals	lb.	.25	—	.30
Sulphur chloride	lb.	.07½	—	09
Sulphur, crude	ton	35.00	—	37 50
Sulphur dioxide, liquid, cylinders	lb.	.10	—	.12
Sulphur, (sublimed), flowers	100 lb.	3.05	—	3.15
Sulphur, roll, (brimstone)	100 lb.	2.70	—	3.10
Tin bichloride, (stannous)	lb.	.22½	—	.25
Tin oxide	lb.	.63	—	.66
Zinc carbonate, precipitate	lb.	.18	—	.20
Zinc chloride, gran	lb.	.13½	—	.14
Zinc cyanide	lb.	.49	—	.50
Zinc dust	lb.	.12	—	.13
Zinc oxide, dry American	lb.	.09	—	.11½
Zinc sulphate	lb.	.03¾	—	.04

Coal Tar Products—Intermediates, etc.

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	1.00	—	1.10
Alpha naphthol, refined	lb.	1 50	—	1 25
Alpha naphthylamine	lb.	.40	—	45
Aniline oil, drums extra	lb.	.22	—	24
Aniline salts	lb.	.32	—	.34
Anhtracene, 80% in drums (100 lb.)	lb.	$0.50	—	$.75
Benzaldehyde (f.f.c.)	lb.	1 30	—	1.50
Benzidine, base	lb.	1.00	—	1 15
Benzidine, sulphate	lb.	95	—	1 00
Benzoic acid, U. S. P.	lb.	1 00	—	1 25
Benzoate of soda, U. S. P.	lb.	1.00	—	1 25
Benzol, pure, water-white, in drums (100 lb.)	gal.	.22	—	.27
Benzol, 90%, in drums (100 lb.)	gal.	.22	—	.27
Benzyl chloride, 95-97%	lb.	35	—	38
Beta naphthol benzoate	lb.	5 50	—	6 00
Beta naphthol, sublimed	lb.	65	—	.....
Beta naphthylamine, sublimed	lb.	2.25	—	2 35
Cresol, U. S. P., in drums (100 lb.)	lb.	.18	—	.....
Ortho-cresol, in drums (100 lb.)	lb.	.23	—	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	.90	—	.95
Cresylic acid, 95-97%, dark, in drums	gal.	.85	—	.90
Cresylic acid, 50%, first quality, drums	gal.	.60	—	.....
Dichlorbenzol	lb.	15	—	20
Diethylaniline	lb.	2 25	—	2 75
Dinitrobenzol	lb.	.28	—	33
Dinitrochlorbenzol	lb.	.28	—	30
Dinitronaphthaline	lb.	.45	—	.55
Dinitrotoluol	lb.	40	—	50
Dinitrophenol	lb.	.32	—	34
Dimethylaniline	lb.	55	—	.60
Dip oil, 25% tar acids, car lots, in drums	gal.	.38	—	.....
Diphenylamine	lb.	70	—	75
H-acid	lb.	2 15	—	2 15
Metaphenylenediamine	lb.	1 55	—	1 75
Monochlorbenzol	lb.	.12	—	.14
Naphthalene, flake	lb.	.07	—	.08
Naphthalene, balls	lb.	10½	—	11½
Naphthionic acid, crude	lb.	1 20	—	1.30
Naphthalene, crushed in bbls. (250 lb.)	lb.	.07	—	.08
Naphthylamin-di-sulphonic acid	lb.	1.00	—	1.10
Nitro naphthaline	lb.	.40	—	.45
Nitro toluol	lb.	40	—	45
Ortho-amidophenol	lb.	6 00	—	7.00
Ortho-dichlor-benzol	lb.	.15	—	.20
Ortho-toluidine	lb.	40	—	45
Ortho-nitro-toluol	lb.	40	—	45
Para-amidophenol, base	lb.	3 25	—	3 65
Para-amidophenol, H. C. l.	lb.	3 25	—	3 75
Para-dichlor-benzol	lb.	15	—	20
Paranitraniline	lb.	1 15	—	1 25
Para-nitro-toluol	lb.	1.50	—	1 60
Paraphenylenediamine	lb.	3 15	—	3 25
Para toluidine	lb.	1 50	—	1 70
Phthalic acid anhydride	lb.	2 50	—	3 00
Phenol, U. S. P. drums (dest.), (240 lb.)	lb.	.08	—	10
Pyridine	gal.	$2.50	—	.....
Resorcin, technical	lb.	4 25	—	45
Resorcin, pure	lb.	6 75	—	7 00
Salicylic acid, U. S. P	lb.	30	—	35
Salol	lb.	.75	—	85
Solvent naphtha, water white, in drums, 100 gal.	gal.	.20	—	.25
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.18	—	.20
Sulphanilic acid, crude	lb.	.25	—	.30
Toluidine	lb.	2 15	—	2 25
Toluidine-mixture	lb.	.70	—	75
Toluol, in tank cars	gal.	.22	—	.24
Toluol, in drums	gal.	.25	—	.27
Xylol, pure, in drums	gal.	.37	—	.45
Xylol, pure, in tank cars	gal.	.35	—	.....
Xylol, commercial, in drums, 100 gal.	gal.	.32	—	.40
Xylol, commercial, in tank cars	gal.	.30	—	.....

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	.36	—	.39
Beeswax, refined, yellow	lb.	.42	—	.45
Beeswax, white pure	lb.	.62	—	.65
Carnauba, No. 1	lb.	.78	—	.80

Carnauba, No. 2, regular	lb.	.65 —	.70
Carnauba, No. 2, North Country	lb.	.50 —	.53
Carnauba, No. 3, North Country	lb.	.40 —	.43
Ceresin, yellow	lb.	.15 —	.18
Ceresin, white	lb.	.16 —	.19
Japan	lb.	.14 —	.15
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.07 —	.08½
Paraffine waxes, crude scale, 117-119 m.p.	lb.	.08 —	.08½
Paraffine waxes, crude scale, 124-126 m.p.	lb.	.08 —	.08½
Paraffine waxes, refined, 118-120 m.p.	lb.	.09½ —	.10
Paraffine waxes, refined, 123-125 m.p.	lb.	.10 —	.10½
Paraffine waxes, refined, 128-130 m.p.	lb.	.11 —	.....
Paraffine waxes, refined, 130-132 m.p.	lb.	.11½ —	.11½
Paraffine waxes, refined, 133-135 m.p.	lb.	.11½ —	.12
Paraffine waxes, refined, 135-137 m.p.	lb.	.12½ —	.13
Stearic acid, single pressed	lb.	.17 —	.18
Stearic acid, double pressed	lb.	.18 —	.19
Stearic acid, triple pressed	lb.	.20 —	.22
Spermaceti	lb.	.30 —	.32

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lbs.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.		$0.68
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.		.45
Pine tar oil, ref., sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.		.33
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.		.58
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.		.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.		.61
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.		.24
Hardwood oil, f.o.b. Mich., sp. gr., 1.06-1.08	gal.		.24
Pinewood creosote, ref.	gal.		.48

Naval Stores

The following prices are F.o.b., New York, for carload lots.

Rosin B-D, bbl.	280 lb.	$12.50 —	$12.70
Rosin E-I	280 lb.	12.60 —	13.40
Rosin K-N	280 lb.	13.50 —	14.50
Rosin W. G.-W. W.	280 lb.	15.00 —	15.50
Wood rosin, bbl.	280 lb.	12.25 —	.....
Spirits of Turpentine	gal.	.77½ —	.78
Wood Turpentine, steam dist	gal.	.72 —	.....
Wood Turpentine, dest. dist	gal.	.67½ —	.....
Pine tar pitch, bbls.	200 lb.	8.00 —	8.25
Tar, kiln burned, bbl. (500 lbs.)	bbl.	12.50 —	13.50
Retort tar, bbl.	280 lb.	13.50 —	14.50
Rosin oil, first run	gal.	.68 —	.78
Rosin oil, second run	gal.	.70 —	.80
Rosin oil, third run	gal.	.82 —	.83
Rosin oil, fourth run	gal.	.85 —	.95

SOLVENTS

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

FISH OIL

Winter pressed Menhaden	gal.	$0.85
Yellow bleached Menhaden	gal.	.87
White bleached Menhaden	gal.	.89
Blown Menhaden	gal.	.95

Vegetable Oils

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls.	lb.	$0.22 —	$0.25
Castor oil, AA, in bbls.	lb.	.24 —	.25
China wood oil, in bbls.	lb.	.18 —	.19
Cocoanut oil, Ceylon grade, in bbls	lb.	.15 —	.15½
Cocoanut oil, Cochin grade, in bbls	lb.	.16½ —	.17
Corn oil, crude, in bbls.	lb.	.18 —	.17½
Cottonseed oil, crude (f.o.b. mill)	lb.	.17½ —	.....
Cottonseed oil, summer yellow	gal.	.21 —	.22
Cottonseed oil, winter yellow	gal.	.23 —	.25
Linseed oil, raw, car lots	gal.	1.50 —	1.53
Linseed oil, raw, tank cars	gal.	1.48 —	1.49
Linseed oil, boiled, car lots	gal.	1.53 —	1.55
Olive oil, commercial	gal.	2.25 —	2.50
Palm, Lagos	lb.	.15 —	.20
Palm, bright red	lb.	.13 —	.18
Palm, Niger	lb.	.12 —	.15
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.18½ —	.19
Peanut oil, refined, in bbls.	lb.	.19½ —	.21
Rapeseed oil, refined, in bbls.	gal.	1.50 —	1.65
Rapeseed oil, blown, in bbls.	gal.	1.65 —	1.70
Soya bean oil (Manchurian), in bbls., N. Y.	lb.	.15½ —	.16
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.14 —	.14½

Miscellaneous Materials

All Prices F.o.b., N. Y.

Barytes, domestic, white, floated	ton	$30.00 —	$36.00
Barytes, off color	ton	22.00 —	27.00
Blanc fixe, dry	lb.	.03½ —	.04½
Blanc fixe, pulp	ton	30.00 —	45.00
Casein	lb.	.17 —	.19
Chalk, English, extra light	lb.	.05 —	.07
Chalk, English, light	lb.	.04½ —	.06
Chalk, English, dense	lb.	.04 —	.05
China clay (Kaolin), imported, lump	ton	35.00 —	.....
China clay (Kaolin), imported, powdered	ton	60.00 —	.....
China clay (Kaolin), domestic, lump	ton	15.00 —	20.00
China clay (Kaolin), domestic, powdered	ton	35.00 —	40.00
Feldspar	ton	11.00 —	15.00
Fluorspar, acid grade, lump, f.o.b. mines	net ton	30.00 —	37.00
Fluorspar, acid grade, ground, f.o.b. mines	net ton	40.00 —	45.00
Fuller's earth, domestic, powdered	ton	30.00 —	40.00
Fuller's earth, imported, powdered	ton	..... —	.....
Graphite, domestic	lb.	.06 —	.12
Graphite, Ceylon	lb.	.08 —	.18
Graphite, Madagascar	lb.	.10 —	.15
Graphite, Mexican	lb.	.01¼ —	.03½
Pumice stone, imported	lb.	03 —	06
Pumice stone, domestic	lb.	None	
Shellac, TN	lb.	.47 —	.49
Shellac, D.C.	lb.	.73 —	.75
Shellac, V. S. O.	lb.	.72 —	.76
Shellac, Diamond I.	lb.	.72 —	.74
Shellac, orange, fine	lb.	.54 —	.57
Shellac, orange, superfine	lb.	.54 —	.58
Shellac, A.C. garnet	lb.	.47 —	.50
Shellac, bleached, bone dry	lb.	.57 —	.....
Shellac, bleached, fresh ground	lb.	.46 —	.47
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	20.00 —	60.00
Talc, imported	ton	Nominal	

Refractories

Following prices are f. o. b. works:

Chrome brick	net ton	$120.00 at Chester, Penn.
Chrome cement	net ton	65.00 at Cheater, Penn.
Clay brick, 1st quality fireclay	net ton	40–30 at Clearfield, Penn.
Clay brick, 2nd quality	net ton	38–48 at Clearfield, Penn.
Magnesite, dead burned	net ton	32.50–35.50 at Chewalah, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80–90 at Chester, Penn.
Silica brick	net ton	45–55 at Mt. Union, Penn.

Ferro-alloys

All prices f. o. b. works.

Ferro-titanium, carbon free	lb.	$0.40 —	.....
Ferro-carbon-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.	net ton	$200.00 —	$300.00
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.32 —	.40
Ferro-chrome, per lb. of Cr. contained, 4-6% carbon	lb.	.70 —	.....
Ferro-manganese, 70-80% Mn	gross ton	130.00 —	150.00
Spiegeleisen, 16-20% Mn	gross ton	40.00 —	50.00
Ferro-molybdenum, per lb. of Mo	lb.	2.75 —	3.00
Ferro-silicon, 50%	gross ton	90.00 —	115.00
Ferro-silicon, 75%	gross ton	150.00 —	175 00
Ferro-silicon, 10-15%	gross ton	50.00 —	60.00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	1.30 —	1.60
Ferro-uranium, 35-50%, of U	lb.	7.00 —	.....
Ferro-vanadium, 30-40%, per lb. of contained V.	lb.	5.50 —	7.00

Resales and overstocks make above prices approximate.

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	0.70	
Chrome ore, 48% and over	unit	$1.00 —	$1.25
Coke, foundry, f.o.b. mines	net ton	4.50 —	5.00
Coke, furnace, f.o.b. mines	net ton	3.75 —	4.75
Petroleum coke, f.o.b. Atlantic seaboard	net ton	16.00 —	16.50

Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	3.00 —	3.25

Resales and overstocks make above prices approximate.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags	bbl.	$2.30
Lump lime, common, including container	300 bbl.	2.65
Common brick, at dock	M.	15.00
Hollow building tile, } 8x12x12	M.	194.40
At factory, Perth Amboy, N. J., } 12x12x12	M.	291.60
Yellow pine, 3x4 to 8x8, 20-24 ft. long	M.	39.00
Yellow pine, 3x4 to 8x8, 20- 4 ft. long at Chicago	M.	38.50
Yellow pine, 3x4 to 8x8, 20-24 ft. long at St. Louis	M.	35.00
Roofings, tar felt (14 lb. per 100 sq.ft.)	ton	50.00
Roofings, tar pitch (in 400-lb. bbl.)	ton	19.00
Roofings, asphalt pitch	ton	30.00
Roofings, asphalt felt	ton	65.00
Roofings, slate-surfaced shingles, per roll of 108 sq.ft.		2.10
Roofings, slate-finished shingles, 100 sq.ft.		5.50
Linseed oil, raw in barrels	gal.	$1.63
Linseed oil, 5 gal. cans	gal.	1.76
Red lead, dry, 100 lb. keg	lb.	.13
Red lead, in oil, 100 lb. keg	lb.	.14½
Red lead, dry, 5 lb. cans	lb.	.15
Red lead, in oil, 5 lb. cans	lb.	.16½
White lead, dry and in oil, 100 lb. keg	lb.	.13
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	.13½
White lead, dry and in oil, 5 lb. cans	lb.	15

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.66
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, cnnehead for boilers, ¾-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.35
Sheets, No. 10 blue annealed	100 lb.	3.55
Sheets, No. 28 galvanized	100 lb.	5.70

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

California

PASADENA—The city will join with South Pasadena and Alhambra in constructing sewerage treatment works on the tri-city sewer farm. Bond will be voted for project. R. V. Orbison, city engineer.

SACRAMENTO—The city plans election in May to vote on $2,400,000 bonds to purchase a site and build a filtration plant, pumping plant and caisson in the Sacramento River. F. C. Miller, City Hall, engineer.

SAN FRANCISCO—The Sherwin-Williams Co., 601 Canal St., Cleveland, Ohio, plans to build a paint and varnish factory here. Estimated cost between $250,000 and $300,000.

Connecticut

BRISTOL—The New-Departure Manufacturing Co., 269 North Main St., has awarded the contract for the construction of a 2-story, 30 x 103-ft. laboratory, to the Torrington Building Co., 197 Water St., Torrington. Estimated cost, $25,000.

HARTFORD — The Hartford Rubber Works, Park and Bath Aves., has awarded the contract for the construction of a 1½-story, 60 x 79-ft. factory on Bartholomew Ave., to J. H. Grozier Co., 221 Main St. Estimated cost, $34,000.

STORRS—The State Legislature, Capitol, Hartford, has appropriated $15,000 to build and equip a temporary laboratory for the Connecticut Agricultural College here.

Iowa

ROCK ISLAND—C. U. Scott & Son, 1338 2nd Ave., Davenport, plan to build a galvanizing, sheet metal and tempering plant on 1st Ave., between 15th and 16th Sts., here.

Kentucky

LEXINGTON—The W. J. Flescher Petroleum Co., 151 East High St., plans to build a refinery having a daily capacity of from 3,000 to 5,000 barrels.

Louisiana

BATON ROUGE—The Island Oil Co., 62 Cedar St., New York City, a subsidary of the New York Stock Exchange, Stock Exchange Building, New York City, plans to build a refinery here.

Maryland

HAGERSTOWN—The American Agricultural Chemical Co., capitalized at $100,000,000, has purchased three farms near here and plans to build a chemical and fertilizer plant.

Massachusetts

CHICOPEE—The Paper Makers' Chemical Co., Holyoke, plans to build a 1- and 2-story, 300 x 500-ft. paper factory on Grattan St., here. Estimated cost, $100,000.

CLINTON—The city plans to build a filtration system. Parker & Bateman, city engineers.

STOUGHTON—The United States Rubber Co., Broadway and 58th St., plans to build an addition to its factory here.

WORCESTER — The Greenman Steel Treating Co. plans to build a 1-story, 40 x 80-ft. plant.

Michigan

DETROIT—The Board of Water Commissioners, 232 Jefferson Ave., has awarded the contract for furnishing 100,000 lb. of liquid chlorine to the Hooker Electro Chemical Co., 40 Wall St., New York City, N. Y., at $.05¼ per lb.

DETROIT—The General Motors Corp., Boyer-Campbell Bldg., is having plans prepared by A. Kahn, architect, Marquette Bldg., for the construction of a 4-story, 60 x 480-ft. research laboratory building on Cass and Milwaukee Aves., same to be equipped with apparatus for a complete chemical, metallurgical and material testing laboratory.

HIGHLAND PARK—The city will soon award the contract for the construction of a filtration plant, to include a 2-story, 29 x 32-ft. head house and a 3-story, 32 x 85-ft. filter house, for the Dequindre Ave. Station of the Highland Park waterworks. D. C. Gewing, city clerk.

JACKSON—The city is having a study made by Alvord & Burdick, engineers, 8 South Dearborn St., Chicago, Ill., for the construction of a sewage disposal system to consist of deep settling tanks and intercepting sewers.

MONROE—The city plans to build a filtration plant. J. White, city engineer.

Minnesota

KEEWATIN—The city has awarded the contract for building extensions to its sewerage system and a sewage disposal plant to E. W. Coons Construction Co., Hibbing, at $59,184.

Missouri

CARONDOLET (St. Louis P. O.)—The Mineral Refining & Chemical Corp. will receive bids about June 1 for the construction of a paint and pigment plant on the Mississippi River front. Plans include a chemical laboratory, mineral milling plant, etc. Estimated cost, $2,500,000. M. Alayo, vice-president.

Nebraska

OMAHA—The Board of Education will install six laboratories in the new High School of Commerce which it plans to build. F. W. Clark, 623 Brandeis Building, architect.

New Jersey

ASBURY PARK—The Victory Tire & Rubber Co., 385 East 149th St., New York City, N. Y., plans to build a 2-story rubber factory on Railroad Ave. Estimated cost, $125,000. E. A. Arend, Kinmoth Building, architect.

HILLSDALE—The Bristol-Myers Co., 277 Greene Ave., Brooklyn, N. Y., has awarded the contract for the construction of a 1-story, 75 x 95-ft. extension to its chemical building, and a 5-story, 80 x 300-ft. manufacturing building, to the Turner Construction Co., 244 Madison Ave., New York City, N. Y.

TRENTON—The city plans to build a 2-story alum plant on Enterprise Ave. Estimated cost, $10,000. J. R. Fell, 134 North Clinton Ave., engineer.

New York

BROOKLYN—The Polytechnic Institute, 85 Livingston St., is in the market for two steel measuring or storage tanks, to be installed in its hydraulic laboratory for cold water storage.

GREENFIELD—The Waco Development Co., recently incorporated, plans to build a plant here. Mining machinery for feldspar mining will be installed in same. Address E. H. Cohen, 236 Union St., Schenectady.

MALDEN BRIDGE—The Gatti-McQuade Paper Co., 200 5th Ave., New York City, has purchased the Peaslee Mills here and is having plans prepared for repairing and altering same for its own use. Estimated cost, $25,000.

MILTON—The Waco Development Co., recently incorporated, plans to build a plant here. Mining machinery for feldspar mining will be installed in same. Address E. H. Cohen, 236 Union St., Schnectady.

NEW YORK—The Crystal Chemical Co., 861 Westchester Ave. (Bronx Borough), has awarded the contract for altering its 6-story, 40 x 70- and 30 x 42-ft. factory at 142-146 Willis Ave., to W. L. Phelan, 2045 Ryer Ave. Estimated cost, $25,000.

ROCHESTER—The Industrial Development Committee, Chamber of Commerce, is having plans prepared for a large shipyard on the lower Genesee River near lake harbor. A cement testing laboratory will be installed in same.

ROCHESTER—The Technical Glass Apparatus Co., Inc., plans to extend its facilities and install new machinery for the manufacture of scientific and laboratory glassware. F. C. Mueller, president.

TUCKAHOE—The Hodgeman Rubber Co. has awarded the contract for the construction of a 1-story, 50 x 150-ft. factory to Kelly & Kelly, East 12th St. and Vernon Ave., Long Island City. Estimated cost, $15,000. Noted Mar. 15.

North Carolina

BREVARD—The Transylvania Tanning Co. plans to rebuild its plant recently destroyed by fire, entailing a loss of $1,000,000.

Ohio

AKRON—The Mohawk Rubber Co., 2nd Ave., has awarded the contract for the construction of a 60 x 200-ft. rubber factory to W. A. Franklin Sons Co., 247 Cuyahoga St. Estimated cost, $50,000.

CINCINNATI—The city plans to build a garbage incinerator. Bonds must be voted for the project. F. Krug, city engineer.

CLEVELAND — The Commissioner of Purchases & Supplies, Room 219, City Hall, will receive bids until May 6 for the construction of a sewage disposal plant on West 58th St. (westerly site).

COLUMBUS—The American Rolling Mills Co. is receiving bids for extensive remodeling and new construction work at its plant along the tracks of the Toledo & Ohio Central R.R. on Parsons Ave. Work includes relining two furnaces, putting in eight hot-blast stoves, raising number of former stoves and building gas dry cleaning plant. Estimated cost between $300,000 and $400,000. J. C. Miller, Middletown, local manager.

NEWPORT—The city plans to build a garbage incinerator.

WAUSEON—The city plans election soon to vote on $170,000 for the construction of a water supply and filtration plant.

Pennsylvania

BEAVER FALLS—The city plans an election soon to vote on $125,000 bonds; part of proceeds to be used for the construction of a new sewage disposal plant. H. T. Barker, city clerk.

ELLWOOD CITY—The city plans an election soon to vote on $85,000 bonds; part of proceeds will be used for the construction of a disposal plant.

REYNOLDSVILLE—The Elk Tanning Co. plans to enlarge its plant here.

Texas

DALLAS—The Texas Producing & Refining Co., recently incorporated with $5,000,000 capital, plans to build an oil refinery here. The plant will be constructed in units, the first to have a capacity of 4000 bbl. daily, with other units added until the ultimate capacity will reach 15,000 bbl. daily. J. F. Smith, Southwestern Life Building, president.

DUBLIN—The State Refining Association has purchased a site here and plans to build an oil refinery. B. R. Anderson, president.

EASTLAND—The Alamo Oil & Refining Co. has purchased a site and plans to build a 1200-bbl. oil refinery.

EL PASO—Z. T. White, 527 First National Bank Bldg., and associates plan to build a 3000-bbl. oil refinery here.

FT. WORTH—F. P. Peterson, 307 West 4th St., and others, plan to form a company and build a plant for the manufacture of paints, grease, lubricating oils and floor sweep compound, on a site now occupied by the Brewton Oil Co., North Main St. and the Frisco tracks.

HOUSTON—The Galena-Signal Oil Co., 17 Battery Pl., New York City, N. Y., plans to increase the capacity of its oil refinery on the ship channel, near here, to 16,000 bbl. per day.

RANGER—The city has awarded the contract for the construction of a new

sewerage system and sewage disposal plant to the James Construction Co., 812 2nd Ave. N., Seattle, Wash. Estimated cost, $155,000. Noted Feb. 1.

Utah

CASTLEGATE—The Rainbow Petroleum Products Co., 4th and 5th West and 7th and 8th South Sts., Salt Lake City, plans to build the first unit of its new plant on the oil shale property near here, same to have a daily capacity of 100 tons.

Virginia

NORFOLK — The Mexican Petroleum Corp., Whitney Bldg., New Orleans, La., plans to build a plant here. W. E. Wimbish, manager.

PETERSBURG — W. H. Camp, Inc., Wharf, plans to build a 1-story fertilizer plant, and is in the market for machinery for mixing chemicals. Estimated cost, $55,000.

West Virginia

MARTINSBURG—The city plans to build a sewerage system and sewage disposal plant. T. W. Sparrow, city engineer.

Wisconsin

GREEN BAY—Kimberly & Clark, Neenah, plans to build a 2-story, 30 x 90-ft. addition to its paper mill here. Estimated cost, $20,000.

MANITOWOC—The Aluminum Goods Manufacturing Co., 150 Franklin St., has awarded the contract for the construction of a 6-story, 70 x 430-ft. factory and office building to W. W. Oeflein, 136 Hanover St., Milwaukee. Estimated cost, $500,000.

SHEBOYGAN—The Dodge Tanning Co., South Water St., has awarded the contract for the construction of a 3-story, 100 x 250-ft. tannery to H Loesing, 914 Superior Ave. Estimated cost, $60,000.

TWO RIVERS—The Aluminum Goods Manufacturing Co., 150 Franklin St., Manitowoc, has awarded the contract for the construction of two 3-story, 60 x 200 and 42 x 137-ft. factory buildings to W W. Oeflein, 136 Hanover St., Milwaukee. Estimated cost, $500,000.

Ontario

DUNDAS—The Town Council plans to build a sewage disposal plant. Estimated cost, $50,000. J. S. Fry, clerk.

TORONTO—W. Harris & Co. will soon receive bids for the construction of a 4-story, 66 x 145-ft. glue factory on Keating St. A Chapman, Harbor Building, architect.

Quebec

LAC AU SAUMON—The Salmon Lake Drive & Boom Association, Ltd., plans to build a large wood and pulp plant.

Mexico

PALO BLANCO—The Island Oil Co., 62 Cedar St., New York City, N. Y., a subsidary of the New York Stock Exchange, Stock Exchange Bldg., New York City, plans to build a refinery here.

Coming Meetings and Events

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its Summer meeting at Boston, Mass., June 18-21. A symposium is planned on electric furnaces.

THE AMERICAN ASSOCIATION OF ENGINEERS will hold a meeting at 29 S. LaSalle St., Chicago, May 13 and 14.

THE AMERICAN IRON & STEEL INSTITUTE will hold its next meeting on May 23-24 at the Hotel Pennsylvania, New York.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 22nd annual meeting at Atlantic City, N. J., June 24-27. The headquarters will be at the Hotel Traymore.

THE AMERICAN ZINC INSTITUTE will hold its annual meeting at St. Louis, Mo., June 9-10.

THE NATIONAL FERTILIZER ASSOCIATION will hold its 26th annual convention the week of June 23 at the Hotel Griswold, Eastern Point, New London, Conn.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its Spring meeting, June 11-14 inclusive.

THE NEW JERSEY CHEMICAL SOCIETY will hold its Spring invitation meeting in the Chemical Building, Rutgers College, New Brunswick, N. J., Saturday, May 10, 1919. Dinner will be served in the University dining hall at 7 P. M.

Industrial Notes

MR. OTTO MANTIUS has moved his offices from the Woolworth Bldg. to 15 East 40th St., New York City.

MR. FREDERICK H. MINARD announces that on May 1 his offices will be moved to larger quarters at 21 East 40th St., New York City.

THE CHICAGO PNEUMATIC TOOL CO., Chicago, Ill., announces the appointment of Mr. T. J. Hudson as acting manager of the pneumatic tool sales division, effective April 15, 1919, succeeding Mr. F. H. Waldron, who returns to Minneapolis as district manager of sales in that territory.

THE SCHAFFER ENGINEERING & EQUIPMENT CO. has changed its location from Tiffin, Ohio, to the Peoples Bank Bldg., Pittsburgh, Pa.

MR. FRANK H. NICKLE, Saginaw, W. S., Mich., has placed on the market several styles of agitator driving yokes, suitable for all kinds of liquid containers.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 174, Abstracts of Current Decisions on Mines and Mining, reported from May to September, 1918. By J. W. Thompson; Tech. Paper 96, Fume and Other Losses in Condensing Quicksilver from Furnace Gases. By L. H. Duschak and C. N. Schuette; Tech. Paper 203, Labor Saving at Limestone Quarries. By Oliver Bowles; Tech. Paper 215, Accidents at Metallurgical Works in the United States During the Calendar Year 1917. Compiled by Albert H. Fay; Tech. Paper 217, Saving Coal in Steam Power Plants. Reprint of Engineering Bull. No. 2, prepared by the U. S. Fuel Administration in collaboration with the Bureau of Mines; Tech. Paper 221, Saving Steam in Industrial Heating Systems. Reprint of Engineering Bull. No. 6, prepared by the U. S. Fuel Administration in collaboration with the Bureau of Mines; War Minerals Series No. 10, Electric Smelting of Domestic Manganese Ores. By H. W. Gillett and C. E. Williams; Schedule No. 13, March 5, 1919. Procedure for Establishing a List of Permissible Self-Contained Mine Rescue Breathing Apparatus.

NEW BUREAU OF STANDARDS PUBLICATIONS: Technologic Paper No. 109, Conservation of Tin in Bearing Metals, Bronzes, and Solders. By G. K. Burgess and R. W. Woodward, issued March 15, 1919; Circular No. 78, Solders for Aluminium, issued Jan. 28, 1919; Technologic Paper No. 114. A Portable Cubic-Foot Standard for Gas. By M. H. Stillman, issued January 28, 1919, price, 5 cents.

THE YOUNGSTOWN PUBLIC LIBRARY has inaugurated a service for vocational study that may well be copied by other city libraries. It has issued a 12-page booklet on the industries of Youngstown, put up in an attractive two-color cover carrying an industrial design of a blast-furnace plant. The following subjects are covered: General engineering, mechanical engineering, steam engineering, electrical engineering, machine design, machine shop practice, general chemistry, analytical chemistry, industrial chemistry, fuels, coal-tar by-products, general metallurgy, iron and steel, electric furnaces, rubber, etc.

"THE SURFACE OXIDATION AND COLORATION OF METALS" is the subject of a pamphlet published by Dr. Tito Rondelli, 31 Via Carlo Alberto, Turino, Italy, setting forth the details of the "Sestini-Rondelli" electrolytic process.

The Rude Awakening

IT WAS not to be expected that the Germans would receive the treaty in the spirit of defeated sportsmen, for as has been pointed out in this journal there is no equivalent in their language for the English word "sportsman," and the German mind probably is devoid of an instinct for which it has no distinctive word. And speaking of words not in the German dictionary, MR. JAMES M. BECK commented in a speech before the English-Speaking Union in London on the absence of any equivalent in German for the English exclamation "Bully!" " It seems strange," he added, "because they give so many exhibitions of the characteristics of the bully."

Throughout the war German psychology has been a source of wonderment to the rest of the world, because just when the mystery of it seemed to be understood, new and strange phases were exhibited. The arrogance and insolence displayed when they were apparently winning the war and which led them to announce boldly the terms which they would exact of their defeated enemies are exhibitions of the same spirit that now whines over the realization of its defeat. Whom the gods would destroy they first make mad, and the German madness of the last forty years which led to their idea of world conquest certainly has wrought their destruction.

During the Spanish war we had the slogan "Remember the Maine!" but there are so many things to remember in the late war that the mind instinctively falls back upon a card index and a corps of clerks. It behooves us to remember! It's worth recalling some of the unpleasant, disagreeable and atrocious things done by the Germans in this war, if for no other reason than to preserve our balance when the whining and bluffing and mock heroics are indulged in. MR. FRANK H. PROBERT, who recently visited Europe for the Bureau of Mines, traversed the iron-bearing areas of Nancy, Briey, Longwy and Luxemburg, and the coal-bearing regions of Saar and Pas de Calais. He returns with the same story of frightfulness which impresses all who have had an opportunity for personal inspection of those districts.

MR. PROBERT says:

"The mines are not seriously crippled, but what of the steel plants in which the iron ore was smelted? No such atrocity was ever perpetrated against the industrial life of any country. Magnificent plants, comparing favorably with anything we have in the United States, are now but a tangled, twisted mass of structural steel and broken stone. The willful demolition was scientifically planned and systematically carried out. This after the removal of all such mechanical and electrical power units as could be used in Germany. The maliciousness and efficiency with which this crime

against French industry was conducted is almost unbelievable."

So much for the iron and steel industry. Of the French coal fields MR. PROBERT says: "The coal measures are overlain by water-bearing strata, necessitating special methods of shaft sinking and support to keep the mines dry. The steel lining of the shafts was dynamited, letting in the quicksands and flooding the underground workings for many miles. In the entire Pas de Calais region it is estimated that 120 million cubic meters of water must be pumped before mining operations are resumed. Having flooded the mines, the headframes and surface equipment were systematically dynamited, the twisted débris in many cases filling up the demolished shafts. It will probably be five years before this coal district can be rehabilitated and twelve to fifteen years before it gets back to normal pre-war output."

And in contrast to these conditions, the coal industry in the Saar is at the height of production! Meantime Germany calls upon us in the name of humanity, consience, justice—qualities which she has never shown—to have regard for her pitiful estate. The thing which most concerns us now is to stand firmly by the terms of a treaty which has been fairly drawn.

An Opportunity for Co-operative Research

ELSEWHERE in this issue we publish a letter from the Director of the Bureau of Standards calling attention to the decision of the Bureau to devote the sum of $10,000 to research in electroplating. While a good start will be made with this amount, it is apparent that much larger sums should be available in order to prosecute the work vigorously. At the moment we can think of no more appropriate donors of funds than those who would profit most from the results, viz., the electroplaters, and we take advantage of the opportunity to suggest an organization in their ranks for co-operative industrial research.

We speak not unkindly of our friends the electroplaters when we say that the impression prevails that their art has been based on rule-of-thumb development and secret formulæ rather than on scientific investigation and knowledge. Studies made during the war disclosed some fearful and wonderful solutions and "dopes," and brought to light methods and processes as archaic as they were unreasonable. On the other hand, some of the war tasks imposed on electroplaters showed them capable of getting remarkable results.

Our thought is that electroplaters can profit in a marked degree if they will get together and support a research into the fundamentals involved in their business. There is a fertile field of metallurgy, electrochemistry and physics in their art that would respond quickly to cultivation. There is no need to fear disclosure of trade secrets, many of which, by the way, probably would be found valueless; nor would the incentive to private initiative be removed, or the profits from superior skill be lost. These things are aside from the scientific groundwork of the art which would be investigated and elucidated for the benefit of all concerned. A few years of work by enthusiastic men who are now available would contribute more to the advancement of electroplating than anything we can think of, and the cost would be nominal when divided among the large concerns in the industry.

Scholarships In Sweden

WE TAKE pleasure in printing elsewhere in this number the announcement of ten scholarships available for American students in science to continue their studies and research in Sweden, with the information that ten similar scholarships of $1000 per year each have been provided for Swedish students to study in the United States. The American-Scandinavian Foundation of New York has secured the benefaction.

Of course we shall welcome the Scandinavian students here. We are glad to have them come, and hope they may find the enlightenment they desire in our various institutions. We are especially interested, however, in the opportunities for American students in Swedish universities and technological schools. For many years they have been addicted to good scientific habits in that country, and their teaching methods are at once thorough and sound. We have examples of this in PROFESSORS KENDALL of Columbia and TAYLOR of Princeton, both of whom started physical chemistry with no less a person than ARRHENIUS. Who wouldn't like to study physical chemistry under him!

Of course there is the language problem to be met by the stiff American tongue which adjusts itself with remarkable unwillingness to anything but "plain United States," but what with Polish and Russian and all the other Slavonic languages that claim attention, and the admitted requirements of French and Spanish, we see gala days ahead for the language teacher. Swedish should not be more difficult than German, which most of us engaged in science have tackled at one time or another.

The advantages of study in Sweden are peculiar, and students should profit by sojourning in communities in which certain things are better managed than at home. Thus the Swedes know how to take care of their forests, which we do not. Or, if we do know how, we do not put this knowledge into public practice, which is even more inexcusable than ignorance would be. Again, while we have pulp and paper mills that are remarkable examples of applied science, it is a fair guess that, taken by and large, there is better chemical control of this industry in Sweden than in the United States.

In the safety-match industry, although it was imported from Sweden, we turn out better material than do they at present, but we do not know where the better technology may be found. In applied electrochemistry they are well advanced, both in Sweden and Norway; a development which has followed their abounding water-power resources and the native disposition toward research.

They are grand metallurgists, and without attempting to make comparisons, it would be a great opportunity to study the subject in Swedish institutions. The same may be said in relation to pure science, more particularly physics and physical chemistry. Their methods are thorough; they take time enough to avoid the slapdash ways of some of our own institutions, and they have ideals of professional responsibility in science.

Granted the requisite character, intelligence and assiduity on the part of the ten young men to be chosen and to whom the opportunity of study in Sweden is offered, we think them lucky. If they come back to us speaking from their chests like some men from England engaged in an unfamiliar tongue, it will not confuse their speech. If they bring back legends of BEOWULF,

if they become inspired with Ynglinga Saga, if they repeat stories of GUSTAVUS ADOLPHUS and the Tenth and Twelfth Kings CHARLES and draw strange and exotic distinctions between hats and caps, it will do them no harm. And these things may lighten the idle hours of the rest of us. Such a Swedish slant will have a greater value in cultural influence than the convictions which in times past were sometimes brought back to the effect that the origins of righteousness and truth were centered in FREDERICK the Great and OTTO VON BISMARCK.

Cinematic Micrography

THOSE who have had the privilege of seeing the remarkable motion pictures of alternating stress failure exhibited by PROF. H. F. MOORE at the Society for Testing Materials or elsewhere during the past few months were greatly impressed by this recent application of the ubiquitous "moovies." Many of them were already familiar with the application of cinematography to motion study, where its possibilities have not even yet been fully exploited by scientific managers. In conjunction with the microscope, however, it remained for PROF. ARTHUR G. ELDREDGE of the University of Illinois to overcome the apparent difficulties which halted less intrepid investigators.

The layman could not dream of the possibilities of these well-known instruments, the motion camera and the microscope, even singly. Science is far too oblivious of their potency, especially in combination. Add the resources of the ultra-microscope and the ultra-visible rays, and the motion camera appears to be the key whereby the gate to vast areas of research may be opened. The outlook should be very attractive to educational and research institutions, and might well be the animus for revamping the all too meager photographic equipment they commonly possess.

PROFESSOR ELDREDGE'S brief discussion of the elementary principles underlying cinematic micrography appearing elsewhere in this issue should therefore be very interesting to research men, and it is hoped that this important contribution may result in many applications of such a powerful tool to future investigations of chemical and metallurgical engineering problems.

Government Control Of Markets

ONE hears very much less argument these days in favor of "government ownership" or "government control" of anything than was heard one short year ago, or even six months. Zealous JOHN WANAMAKER, when Postmaster General, explained that there were four reasons why the United States did not have a parcels post, those four reasons being the Adams Express Company, the United States Express Company, the American Express Company and the Wells-Fargo Express Company. The public now has several reasons why it does not favor government operation of utilities, among those reasons being government operation of the cables, of the Postal Telegraph-Cable Company, the Western Union and the railroads.

Better than all these reasons, however, because wartime necessity obtrudes itself when one endeavors to extract the essence, is the manner in which the Industrial Board program of "price deflation" or "price stabilization" worked out, for in it one is furnished the C. P. essence of the Washington politico-bureaucratic method of doing things and not accomplishing results.

Wordy as were the exchanges between the Industrial Board and the Railroad Administration before the former resigned, May 9, the remarks afterward made to the public by parties to the controversy quite outclass them. MR. PEEK announced—to the public—that "the public" would demand an explanation why the Industrial Board plan had been wrecked "apparently on the obstinacy of a single individual"—the Director General of Railroads—when "in theory the plan had been approved almost unanimously." Then MR. PEEK rapped the Secretary of the Treasury for taking "a stand in direct contradiction with his message urging the creation of the board." Finally he indicates the point of debarkation for the Attorney General by observing: "The Attorney General has rendered an opinion that the plan of the board contravenes the Sherman act, but the facts he assumes as the basis of that opinion are so inconsistent with the actual course of conduct of the board as to render the opinion inapplicable." To all or much of which the Secretary of the Treasury replies in a public statement that the Industrial Board "was hopelessly committed to an unsound and dangerous policy" and that "there is scarcely one accurate assertion or sane deduction in all the intemperate screed."

MR. PEEK had condemned himself in his statement. He asserted, which was true, that "in theory the plan had been approved almost unanimously," which obviously suggests that there must have been something wrong with the board's method of carrying out the theory, and so there was. The idea was that the board should act as an intermediary between seller and buyer, whereas it agreed only with the sellers and then sought to force the Railroad Administration to accept the terms, which the Railroad Administration refused to do. A function of the board was to be that of restoring the play of the law of supply and demand, but as a means of doing this it endeavored to fix steel prices for a period of nine months!

All these men were very likeable chaps before they went to Washington and got to doing things in a Washington atmosphere, which is the main reason why government operation of anything is to be avoided when it can be.

The Industrial Board acquired a misconception of the fundamental facts in the case, arrived at an improper conclusion, and then made it a personal issue to have others adopt its views. It was deceived as to the cost of making steel, accepting as applicable to the future certain statements of cost which included a heavy overhead because figured upon light operation of mills. The Industrial Board plan, however, contemplated the restoration of activity, and if that occurred the overhead would be much better distributed and the cost of production would be correspondingly lower. The steel producers, who know their market quite well, had no faith in an immediate resumption of constructional activity, and on that basis the reductions they accorded the Industrial Board must be considered large. Now the board is gone and the steel producers doubtless wish they had their old prices back again. And after all the wordy arguments of the past few weeks it is at last developed what the Railroad Administration would like to buy—200,000 tons of rails. That is one-fifteenth of one month's full output of finished steel.

Readers' Views and Comments

Economics in the Zinc Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—I certainly agree with the gentleman who wrote the article entitled Economics in the Zinc Industry in your issue of March 15, 1919, that roasting plays an important part in the smelting of zinc ores and that there is considerable room for improvement in the roasting of ores for the extraction of zinc, more especially with respect to the design of the roaster. From all the results and experiments I have made on samples from the kilns during the process of roasting, the indications are that sulphides do not pass by degrees to sulphates and then to oxides, but more directly to oxides. If this were not the case a greater percentage of the sulphates would be found at certain places along the bed of a mechanical roaster or at certain periods in hand-roasting.

The following results obtained on a hand-rabbled kiln show a low percentage of sulphates at all periods:

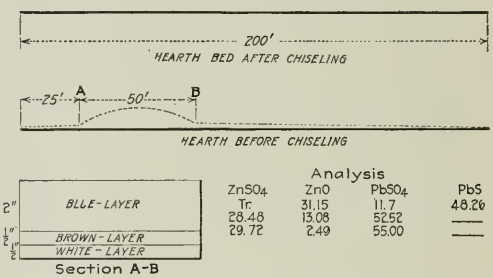
The following results show that the formation of sulphates is very slow and that the oxide of zinc and the sulphide of lead are changed to sulphates, and apparently without the action of much air or rabbling. These samples represent what is called the kiln bottom, and were taken from a Ropp roaster as shown by the sketch.

As the ore is moved forward by the rabble plows, the heavy galena entangled with a certain amount of zinc and iron sulphides is deposited between *A* and *B*, and



gradually grows or builds up to a thickness of from 6 in. to 10 in., when it has to be chiseled out. From the above experiment the indication would be that a thick bed moving slowly through the kiln is a better condition for roasting ores for electrolytic production of zinc than where the distillation process is used; and where the latter process is to be used the roasting kiln should be designed to give an instantaneous roasting condition as near as possible.

In 1913 the writer made the following experiment: A piece of tile $5\frac{3}{4}$ in. by 9 in. was covered with as thin a layer of ore as possible. The ore was then brushed off and weighed. The tile was then inserted into an assay muffle and heated to a good red heat, when it was withdrawn, and the weighed ore quickly spread over, and the tile with ore reinserted into the muffle. The following results were obtained:

	Green Ore Taken, Grams	Time in Muffle, Min.	Per Cent Sulphur
Joplin ore	45	10	2.80
Joplin ore	45	15	1.50
Western ore	45	10	4.07
Western ore	45	15	0.70

Now, as the amount of ore taken was 45 g. and the area of the tile was approximately 50 sq.in., there would be 0.9 g. per sq.in., or 129.6 g. per sq.ft. Taking the area of a regular kiln at 2250 sq.ft., we would have, if the ore were spread over the hearth as in the test, 2250 × 129.6, equal to 291,600 g.; or, dividing by 454, the number of grams in one pound, we would get 642 lb. of roasted ore every 15 min., which is equivalent to 61,632 lb. per 24 hr., based on green ore. This would be considered very good in actual practice. So far as the chemical reactions, heat and air are concerned the principle seems ideal, and it is only a matter of

working out the mechanical details of a suitable kiln. After making this experiment I concluded that a revolving hearth would be best suited to accomplish an instantaneous roast and went so far as to design one and apply for a patent, when I discovered that Mr. Wilfley had already covered the ground. As Mr. Wilfley had not followed up the subject with the installation of a practical roaster on a commercial scale, so far as I knew, I lost interest in the matter. It would be of interest, however, to learn from Mr. Wilfley his experience with the small roaster he built and tested, and whether he thinks there are possibilities along this line.

Henryetta, Okla. E. M. JOHNSON.

That Missing Page From the Blue-Back Speller

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your article "That Missing Page From the Blue-Back Speller" on page 794 of your issue of Dec. 15, I think your question as to the wisdom of adding cold solid additions in the ladle in making steel is pretty well answered by the fact that the steel should be poured at a temperature only very slightly above its liquidus or upper freezing point. Thus the casting temperature should be so low that a considerable skull is often left in the ladle. Moreover, pouring at a temperature materially above the liquidus causes external cracks on the sides of the ingot, from the fact that the rate of thickening of the solid walls of the ingot goes on so slowly as the column of molten steel rises that the ferro-static pressure becomes so great as to crack these walls. Under these conditions the margin of temperature between the freezing point and the existing temperature of the molten steel is so slight that the melting of any solid additions must be relatively slow. The last particles of the addition cannot begin to diffuse or to be spread by convection until they have actually melted. Indeed the molten steel has so slight a margin of temperature above its solidus that large quantities of it may be expected immediately to freeze about any cold solid ferromanganese that is thrown into it, quite as when one thrusts a cold iron rod into a pot of molten glass one will draw out a bunch of glass which may be much thicker than the rod itself. We shall thus have a mass consisting, first, of the cold ferromanganese, and, second, of an envelope probably many times larger than the manganese itself of plastic steel which has solidified about it. The melting of the manganese cannot begin till the whole of this resolidified steel has melted, and the diffusion of the whole of the manganese cannot begin till still later, when the last of the ferromanganese has melted.

Moreover, because the temperature is so much lower in the ladle than in the furnace, the activity of the manganese in removing the oxygen is materially less. This is no doubt the important reason why the loss of manganese is less when it is added in the ladle than when it is added in the furnace.

Actual practice shows that this is not an imaginary condition. In fact when manganese is added in the ladle it has been observed in many cases that the last ingot poured is materially richer in manganese than the first, indicating either that the manganese has been floated to the surface by means of the envelope of steel resolidified about it, or that there have been in effect successive additions of manganese to the molten metal by the successive meltings of the different lumps of ferromanganese, each surrounded with its own envelope of resolidified steel. As each became free from its envelope and in turn melted, it would become added to the molten metal and would no doubt diffuse rapidly through it. Hence the last ingot may be much richer in manganese than the first.

I have had the advantage of discussing this matter with Colonel Barba since reading your article, and I believe his recommendations represent not simply his own opinion, but the result of experience and widespread belief. H. M. HOWE.

Washington, D. C.

Work of the Bureau of Standards on Electroplating

To the Editor of Chemical & Metallurgical Engineering

SIR:—As was stated in January in the *Monthly Review* of the American Electroplaters' Society, efforts were made to secure from Congress a small special fund for work in this field. Owing to the many demands upon Congress at that time, it was not possible to secure this or numerous other special funds requested by the Bureau. However, in view of the importance of electroplating to many industries, and of the advantage of continuing the investigations now in progress, it has been decided to make an allotment of $10,000 for this work from the Industrial Research Fund recently appropriated to the Bureau for the year beginning July 1, 1919. Reports upon the progress and results of this work will be published from time to time in this and other technical journals, and in Bureau publications.

Even with the annual expenditure of this sum, it will require a considerable period to study the many kinds and problems of electroplating. More rapid progress could no doubt be made if additional funds were available. If, therefore, the platers or manufacturers interested in electroplating desire to contribute to the support of this work, preferably through the American Electroplaters' Society, satisfactory arrangements can no doubt be made. Such support might either take the form of annual subscriptions from firms, or of the employment by firms themselves of persons to work at and under the direction of the Bureau of Standards upon some problem of general interest. In the latter case the facilities of the Bureau could be employed with the understanding that all the results of such work would be made available to the public.

In order to make this work of value to the industry, it is important that in the future, as in the past, we should receive the active support and assistance of the electroplaters, who are, therefore, encouraged to send to the Bureau information possessed by them, and requests for information desired by them.

Bureau of Standards, Washington, D. C. S. W. STRATTON, Director.

Decomposition of Metals

To the Editor of Chemical & Metallurgical Engineering

SIR:—In my article on "Decomposition of Metals" in your issue of April 15, 1919, there was an error on page 423, first column, first line. The last part of the sentence should read: "we might expect a transformation of β crystals into brittle γ crystals to occur in certain brasses under certain conditions." The sentence as printed had α crystals instead of γ crystals.

Bureau of Standards, Washington, D. C. A. I. KRYNITZKY.

The Oxidation of Ammonia

AT THE May 8 meeting of the Washington Section of the American Chemical Society Dr. Charles L. Parsons presented an interesting paper on the oxidation of ammonia. A brief résumé was first given of European work along this line including a description of the Ostwald process and of the Frank-Caro process. The Ostwald process was first put into commercial operation at Gerthe, Westphalia, in 1909, and later at Vilvorde, Belgium. During the war plants using this process were operated at Angonleme, France, and Dagenham, England. After the beginning of the war in 1914 the Frank-Caro process was developed by the cyanamide interests of Germany and this process was used in the huge German plants later built. It is a matter of surprise that there appeared in the January, 1916, issue of *Metall und Erz* a detailed description of the Frank-Caro process as then developed.

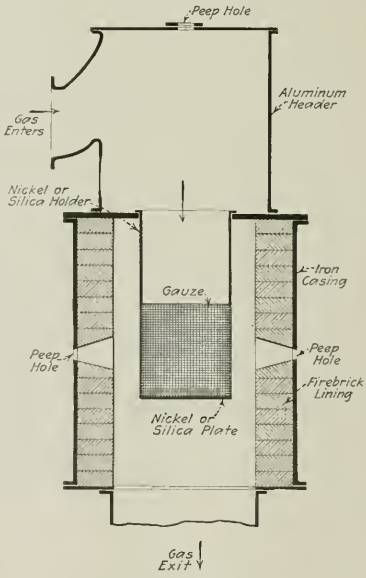
The Frank-Caro apparatus used a flat platinum gauze as a catalyst to promote the reaction in the air-ammonia mixture. The American prototype of this flat gauze converter is the Landis converter of the American Cyanamid Co., first used at Niagara Falls early in 1916, later at Warner's, N. J., and finally installed in the large U. S. Nitrate Plant No. 2 at Muscle Shoals, Ala. The installation at Muscle Shoals has been described by Fairlie in CHEMICAL & METALLURGICAL ENGINEERING, Vol. 20, No. 1, page 8, Jan. 1, 1919.

In August, 1916, the Bureau of Mines entered into a co-operative investigation of ammonia oxidation with the Semet-Solvay Co. Under this arrangement there was put into operation several months later, at the Semet-Solvay's plant near Syracuse, N. Y., a converter of the Landis type using a flat platinum gauze approximately 1 x 2 ft. as a catalyst. The primary purpose of this installation was to determine whether by-product coke-oven ammonia could be oxidized readily by means of such a converter. The apparatus worked well, running on the Semet-Solvay "Grade A" by-product ammonia with high efficiency. The consumption of electrical power for heating the gauze was, however, considerable, and appeared unnecessary in view of the large amount of heat liberated by the oxidation reaction itself. The design of a converter in which the heat developed by the reaction should be utilized to maintain the necessary gauze temperature was therefore undertaken.

It had been noted that the flat gauze converter would operate without electrical heating on a 10 to 12 per cent ammonia-air mixture, but with a lowered efficiency, due apparently to too low a gauze temperature. By simply using three layers of previously activated gauze it was found that fairly high efficiencies would be reached without electrical heating. It appeared, however, that the gauze temperature was still somewhat too low. Attention was then turned to a new design of apparatus in which the previously activated gauze was rolled into a cylinder and supported concentrically in a brick-lined cylindrical casing. One end of the gauze cylinder was closed with a quartz or nickel plate. The air-ammonia mixture was forced in at the other end of the gauze cylinder and passed out through the four layers of gauze forming the cylinder wall. By this arrangement the heat generated by the reaction was conserved to such a degree that a satisfactory operating temperature was maintained in the gauze.

The air-ammonia mixture, containing about 10 per cent of ammonia, is delivered at the top of the converter through an aluminium pipe. The reaction is initiated at the gauze by projecting a small flame against it for a moment until the oxidation reaction starts. The glow soon spreads over the whole gauze. The hot gases leaving the gauze impinge on the brick lining of the outer casing and bring this up to near red heat, so that considerable heat is radiated back onto the gauze. After being put into operation the apparatus requires no further attention. A converter of this type was operated continuously at the Semet-Solvay's plant from February to September, 1918. It was shut down on the latter date only because an inexperienced plant operator allowed caustic solution to back up into it. On a 23-day test run with one of these converters at Syracuse in 1918, an average of 160 efficiency determinations gave 90.7 per cent.

The platinum gauze used is woven of 0.0026-in. diam. wire, 80-mesh per linear inch, and weighs approximately 16½ ounces. The converter is operated with a gas flow of 200 cu.ft. per minute, representing a capacity of about 2½ tons of nitric acid (figured as 100 per cent acid) per day. The gauze must be kept free from iron oxide, oil and the like. Impurities in the gas, such as the phosphine in cyanamide ammonia, or



CATALYTIC CONVERTER

the organic impurities in Grade B by-product ammonia, lower the oxidation efficiency of the converter. It is now known, however, that phosphine can be removed from cyanamide ammonia, either by making aqua ammonia under certain conditions or by passing the gas through a bed of gas-mask charcoal. Also it is known that most of the phosphine can be removed by blowing air through the autoclaves for a short time before the cyanamide is steamed. Since impurities in the ammonia gas lower the gauze temperature, it is evident that either preheating the gas by means of the waste heat

of the reaction or adding electrical heat to the gauze will result in higher efficiency when oxidizing an impure ammonia. The converter operates normally at about 825 deg. on a 10 to 11 per cent ammonia-air mixture. In general the oxidation efficiency at a given gauze temperature is inversely proportional to the percentage of ammonia, but the cylindrical gauze converter will not operate well with much less than 10 per cent ammonia in the gas mix unless a preheater is used. In preheating the air-ammonia mix, the preheater must be so designed that only nickel, aluminium or silicate parts are in contact with the hot gas, for other material decomposes the ammonia.

The cylindrical gauze converter as developed by the Bureau of Mines was slightly modified by the Ordnance Department and installed in U. S. Nitrate Plant No. 1. The results obtained with the converter at this plant, being Ordnance Dept. records, Dr. Parsons was, unfortunately, not at liberty to discuss.

As the last item in his paper Dr. Parsons presented a graph showing the cost of producing nitric acid from Chile nitrate as compared with its production by the oxidation of ammonia and subsequent conversion of the nitrogen oxides to nitric acid of various concentrations. The interesting point was made that, on the basis of the estimates represented, a 94 per cent nitric acid could be made by the ammonia oxidation process (with subsequent concentration) in competition with nitric acid from Chile nitrate when the price of Chile nitrate was 2c. per lb. and cost of producing ammonia 11½c. per lb.; likewise the cost of 50 per cent nitric acid would be the same from the two processes when Chile nitrate cost 2c. per lb. and ammonia 14c. per pound.

Modern Training of the Chemical Engineer

AT A meeting held at the College of the City of New York under the auspices of the College Chemical Society, April 25, Dr. Ralph H. McKee. professor of chemical engineering of Columbia University, presented a paper dealing with certain phases of chemical engineering education, particularly with recent changes in the curriculum.

We may define the scope of a chemical engineer's work by saying that he applies knowledge obtained from the field of pure science and from the field of engineering to the solution of the problems of applied chemistry. Due consideration must be given to the financial element, so that the solution may be commercially practicable.

A process must go through several stages before it becomes a part of chemical industry. After leaving the laboratory, the process is developed in a small-scale plant. If successful, a full-sized plant is next constructed and operated by partially skilled labor, after having been trained by the technical staff. Following the initial operating period, refinements in the process are made by the chemical engineer.

Some fifteen years ago, when chemical engineering was in its infancy, there was considerable discussion as to whether the training of a chemical engineer should be primarily along engineering lines and only secondarily chemical, or vice versa. A number of the larger universities took the former attitude, but at the present time it is conceded that the emphasis should be placed upon the chemical training. It is essential that the instructors should be familiar with actual practice and should not have to rely on text-books. It has been said that text-books of industrial chemistry are mostly descriptions of methods that are obsolete. This statement was made twenty years ago, but it is even more true today. The Chemical Warfare Service took on an average three months to develop a new process and by that time the process was often obsolete. Of course, this work was done under the stress of war-time necessity, but it is, nevertheless, an indication of the changes which are constantly taking place in the industry.

In industries of a mechanical nature, production costs may be distributed approximately as follows: Labor, 35 per cent; materials, 35 per cent; overhead, 30 per cent; while for a chemical plant the cost of labor may vary from 12 per cent to as low as 1 per cent; materials, up to 90 per cent; overhead, in some cases 30 to 35 per cent. It is evident that in the chemical industries, efficiency of operation and maximum output are the main factors governing cost of production. A 3 per cent increase in yield may be equivalent to cutting the labor cost in two.

While the cost of labor is not a major item. labor itself is exceedingly important. The technical force should be well paid and the laborers should be fairly intelligent, as carelessness on their part may result in large losses of valuable materials. Carefulness and willingness of workmen to follow instructions are more important than education. It is interesting to note the possibilities which may result from the employment of psychological tests, such as have been used in the United States Army, in the selection of labor.

Twenty years ago, the chemical engineer studied general chemistry, qualitative and quantitative analysis (including assaying) and text-book work only in metallurgy, organic and industrial chemistry. Ten years ago, physical and electro-chemistry were added to the list, emphasis being placed upon the theoretical treatment of these subjects. At the present time the tendency is to increase the time devoted to laboratory work in the general, organic, physical, electrochemical and industrial chemistry courses, and to cut down the work in qualitative and quantitative analysis, metallurgy and the classroom work in physical chemistry. Assaying is generally omitted. During this same period, in connection with the other college courses, there has been a decrease in the amount of drawing and mechanical engineering required, and civil engineering has been largely eliminated. In their place we find heavier courses in physics, a study of business law, contracts, specifications, etc., and certain phases of biology, such as the utilization of bacteria, yeasts and molds which are capable of producing chemical transformations.

Since there are different requirements for chemical engineers, there should be different kinds of chemical engineers. With this object in view, the present graduate courses in chemical engineering at Columbia University have been chosen primarily for the purpose of training men who may become superintendents and managers of plants, and less for work in industrial research laboratories. The phases of the work given at Columbia but not customarily given in undergraduate curricula of chemical engineering are the following:

1. Chemical factory machinery, including plant construction and apparatus layout.
2. Applied colloid chemistry.
3. Factory wastes disposal.
4. Plant management, including problems relating to

labor, insurance, laws governing dangers, compensation, etc.
5. Efficiency engineering.
6. Laboratory courses using standard semi-factory size equipment.
7. One summer vacation period of eight weeks must be spent by the student in a factory as a laborer in order that he may be able to understand the workman's point of view.
8. In the third year, the student takes up a research problem of a factory type.

So far as I know no university teaches its engineering students the handling of labor and employment. The indications are that these subjects may be satisfactorily taught in the class-room. We at Columbia are trying to work out a method of handling these subjects but we have not yet quite reached the stage where we are ready to offer such courses to our chemical engineering students. Army experience has shown the value of psychological tests, and experiments in scientific labor employment in several factories have proved successful. In one plant employing 6000 persons, it was found necessary to hire 15,000 in 1917, so that the labor turnover was 2½. After the introduction of psychological tests, a report showed that the excess labor amounted to only 3000 per annum, or a labor turnover of 1½. Since it costs from $75 to $300 to break in a new man, depending upon the nature of the work, the importance of reducing labor turnover to a minimum is apparent.

American Scientific Glass

AT the meeting of the New York section of the American Chemical Society, May 9, a symposium on Scientific Glass was held. Harrison E. Howe of A. D. Little, Inc., read the leading paper, in which he reviewed the developments beginning with the work of Fraunhofer, Faraday and Harcourt and through the classical researches of Ernst Abbe and O. Schott at Jena. Since an account has recently been published[1] covering similar ground, only brief mention will be made of some of the new features brought out.

The plate glass slab rolling method has been successfully applied, which facilitates grinding and selection of suitable lens pieces. Motor-driven stirring apparatus has been adopted in place of hand stirring. It is necessary to have sand with less than $\frac{1}{200}$ per cent iron content. Phosgene treatment costs $40 per ton and only removes the iron not sealed in the silica aggregates. The maximum limits of constituents are as follows:

	Per Cent.		Per Cent.
Silica	75	Baryta	50
Alkali	20	Zinc	12
Lime	15	Alumina	5
Lead	7	Boron	20

Dr. A. V. Bleiniger of the Bureau of Standards pointed out the future needs of the industry as being purer raw materials; better data, as there are many gaps in the present curves; a knowledge of annealing theory and a set of optical specifications. The glass pots developed by the Bureau are made of a mixture of open and dense burning clays obtained from Tennessee, Kentucky and Georgia. The resistance of the pot to slagging is due primarily to the closed dense surface of the pots giving a minimum area of reaction contact. Large ton pots are necessary in order to get the ratio of glass volume to pot contact reduced small enough to keep the slagged impurities concentration low enough.

Carl W. Keuffel stated that counter colors or bleaches could not be used because of the resistance to light transmission they set up in the glass. After last September more than adequate supplies of good glass were available—the glass manufacturers passed the instrument makers in the race.

Mr. Harry Rosenthal spoke of the recent celluloid-glass lenses which are not shatterable with a 2-ft.-lb. blow. Color absorbing, and matching glasses are readily made by dyeing the celluloid.

American Institute of Chemical Engineers, Boston Meeting

THE eleventh semi-annual meeting of the American Institute of Chemical Engineers will be held in Boston, Mass., with headquarters at Lenox Hotel, from June 18 to 21, 1919. Following is the official program:

Wednesday, June 18, 1919.
- 9:00 A.M. Registration at Engineers' Club.
- 9:30 A.M. Welcome by the Mayor or his representative and response.
  Business session.
- 10:00 A.M. Reading of papers:
  Symposium on Electric Furnaces.
  The Future of the Electric Furnace, C. T. Bragg, Mich. Smelt. & Ref. Co.
  Utilization of Electric Brass Furnaces, H. W. Gillette, Bureau of Mines.
  Problems Encountered in Electric Furnace Practice, P. E. McKinney, Washington Navy Yard.
  Electric Furnaces of the Resistance Type—Ill. by motion pictures, T. F. Bailey, Electric Furnace Co.
- 12:30 P.M. Luncheon at Engineers' Club.
- 2:30 P.M. Reading of papers:
  Symposium on Electric Furnaces continued.
  Ajax Wyatt Induction Furnace—Slides, G. H. Clamer, Ajax Metal Company.
  Some Practical Results Secured with High-Frequency Induction Furnaces, Dr. E. F. Northrup.
  Booth-Hall Rotating Furnace—motion pictures, Carl H. Booth, Booth-Hall Co.
  The Rocking Electric Arc Furnace, E. L. Crosby, Detroit Elec. Furnace Co.
- 8:00 P.M. Smoker in assembly room, Arthur D. Little, Inc., with inspection of museum and laboratories. The paper mill will be in operation, and arrangements made for special laboratory demonstrations.

Thursday, June 19.
- 9:30 A.M. Board tug for tour of inspection of industrial plants along Boston waterfront, Commonwealth and Fish piers, the largest fish-handling pier in the world.
  Victory shipbuilding plant at Squantum.
  Revere Sugar Refinery.
  Buffet lunch, on tug.
- Afternoon—Edison Power Plant.
  New England Gas & Coke Co.
  Trip by tug to Marblehead.
  Dinner at Eastern Yacht Club.
  Return to Boston by tug, train or auto.

Friday, June 20.
Meeting at Mass. Inst. of Technology.
- 9:00 A.M. Business meeting.
- 10:00 A.M. Reading of papers:
  Growth and Development of the Manufacturing Plant of the Providence Gas Co., W. H. Russell.
  Flash and Burning Points of Gasoline-Kerosene Mixtures, James T. Robson and James R. Withrow.

Chemists Should Be Registered and Licensed, Edward Gudeman.
State Licensing of Engineers and Chemists, James R. Withrow.
Chemists Should Not Be Licensed, A. W. Smith.

12:30 P.M. Luncheon at Walker Memorial, M. I. T.

1:30 P.M. Inspection of laboratories, Mass. Inst. of Technology.
Harvard University, including the Peabody Museum, the Wolcott Gibbs Laboratory of Research Chemistry, and the Jefferson Laboratory of Physical Research.
The Agassiz Museum, The Glass Flower Exhibit, will be open.

4:30 P.M. Historic Boston by sightseeing auto.

7:00 P.M. Dinner at Brookline Country Club.

Saturday, June 21.
All day excursion by train to Lawrence, Mass., for inspection of plants—Champion International Co. (paper) and some of the largest textile plants in the world, as Pacific Mills, Arlington Mills, American Woolen Co.
Return to Boston by train.

Surplus Government Supplies

Sodium nitrate will be sold for the War Department by W. R. Grace Co., Wessell, Duval & Co., and H. B. Baker Co. of New York City and the Du Pont Nitrate Co. of Wilmington, Del.

Sulphur will be sold by the Union Sulphur Co., New York City.

Copper will be sold by the United Metals Selling Co., New York City.

Alcohol will be disposed of, as far as possible, by supplying the needs of the other departments of the Government. Any surplus remaining after all of the bureaus have been amply provided for will be sold back to the producers.

Spring Meeting of the T. A. P. P. I.

The Association will convene Wednesday morning, June 11, at the Hotel Lawrence, Erie, Pa., for inspection trips to the plants of the General Electric Co. and the Hammermill Paper Co. Following a complimentary dinner by the latter company, the Association will leave Erie for Buffalo, where business and technical sessions will be held in the auditorium of the Larkin Co. Paper and pulp manufacturers on both sides of Niagara Falls have offered to open their plants for inspection. Details of these visits will be announced later. Henry F. Obermanns, Hammermill Paper Co., Erie, Pa., and Paul Kellogg, Larkin Co., Buffalo, N. Y., should be notified of the intention to attend.

Chicago Meeting A. I. M. E.

The American Institute of Mining and Metallurgical Engineers will hold its Fall meeting in Chicago, Sept. 22 to 26. This meeting promises to be one of decided importance to the industry, as subjects of vital concern will be under discussion. In addition to the technical talks, an elaborate social programme is being arranged, and excursions by the Institute as a body are planned to many points of interest in the vicinity, including the steel mills at Gary, the oil refineries at Whiting, metallurgical plants at East Chicago and North Chicago, and to the LaSalle district, where the cement, coal and zinc industries are represented.

Industrial and Academic Co-operation

THE much heralded co-operation between industry and technical schools is rapidly becoming a fact. Good evidence of this was shown in Brooklyn at the annual dinner of the Polytechnic Institute Alumni Association and the Chemical and Engineering Societies on May 10. Dr. John C. Olsen was toastmaster and had a complete stock of wit on tap which compensated for the way the wine and Scotch was served, in cubes. Dr. F. W. Atkinson reviewed the progress of the institution, which has grown to 800 students. Eighty thousand dollars was received in donations during the past year, of which $35,000 was subscribed by Dr. William H. Beckers, vice-president of the National Aniline Co., for use in the chemical engineering laboratory. When Dr. Beckers was asked to tell how he managed to build up the large Beckers dye works in the face of German competition before the war, he said that independent American manufacturers could not use imported intermediates very well. His chief product was a blue dye resembling anthracene blue, but actually made of gallic extract and cymene. It was not a fast dye and the Germans quickly persuaded the trade to abandon it by demonstrating the comparative fastness of their anthracene, which was about forty times more fast. However, Dr. Beckers ultimately found out that his dye was good for four seasons' wear and so was able to get and hold onto a fair trade. Dr. Beckers' advice to the chemical alumni was to pick out one or two propositions and persistently stick to them until they were accomplished. To those who had been successful in business he said, "It is not enough that the wealthy trustees give their hundreds or thousands of thousands of dollars in endowments. They must co-operate in their technical work with the technical schools. Ample rewards should be liberally given for results accomplished.

Lt.-Col. Alfred H. White briefly outlined the operations at Muscle Shoals and had most excellent slides shown on the screen. Dr. Frederick de Jahn of the General Chemical Co. was called upon to tell about the G. C. process but preferred to say no more than that they were very successful. The finale was ingeniously worked out by Dr. Irving W. Fay. A large Old Glory was developed by blowing some of the G. C. synthetic ammonia on its once-believed-to-be-all-white-banner-by-the-über-alles-dye-makers-of-the-Rhine and true to form, the colors gleamed forth amid the closing song by the alumni of "The Star-Spangled Banner."

Exchange of American-Scandinavian Scholarships

The American-Scandinavian Foundation announces the establishment of 10 new scholarships beginning with the academic year 1919-1920 for young American scientific students who desire to complete their study and research in Sweden. Each scholarship will provide $1,000 for one year's study and the funds will be provided by Americans who desire to promote interchange of knowledge between the two countries. Similarly, funds are being raised in Sweden to send 10 Swedish students to the United States. Physics, chemistry, hydro-electric engineering and metallurgy are among the subjects offered. Applications will be acted upon by a committee and should be filed before June 1. Papers can be secured from the American-Scandinavian Foundation, 25 West 45th St., New York City.

Photography in Research

A Concise Review of the Applications of Photography in Industry—Illumination, Lenses and Appliances—Motion Microphotographs Record Stresses in Wrought Iron—Opportunities for Development

By ARTHUR G. ELDREDGE

INDUSTRIAL organizations and educational institutions have for some time recognized the value of photography, its chief uses being for records, graphic proof on progress of work, or illustrations for lectures. Investigators would do well to follow in such footsteps, since in science there is absolutely no other means of adequately recording the facts. Words fail completely to portray conditions. Drawings can but poorly convey the texture, minute detail or substance of an object as it really is. Photography does swiftly, accurately and easily these things which by other means are done laboriously or not at all.

Modifications of the simple camera have a limit to their accomplishments. The next step is the microscope. What remarkable things it does for us! On the other side of the eyepiece there awaits a new world, things indescribable, impossible of delineation. Photography steps in, it accentuates color contrasts or eliminates them, it will record the facts for which you seek if used with skill. In the living sciences it reveals for the masses those secrets with which few are acquainted. In mineralogy it shows by polarized light rock structures we could not have guessed. (Figs. 1 and 2.) Modern metallurgical methods and products could hardly exist but for information revealed by the microscope. In this case photography can record the facts of structure and composition for quick comparison.

Surpassing all of these methods is the motion picture. In this instrument we have a tool outstripping the magic of Aladdin. It tells things we would not dare dream. It may prove beyond contradiction things beyond the wildest conjecture. Our eyes are something of a compensating instrument—they can interpret only slow motions, and by reason of the persistence of vision are a complete failure in splitting seconds. Not so the motion picture; with it consecutive pictures of a moving object may be made with exposures varying from one-fifth of a second to one ten-millionth of a second. Pictures taken at excessive speeds when projected at the normal rate of 16 exposures per second permit one to analyze the motions and to understand things entirely beyond ordinary vision.

In the field of research men are endeavoring to uncover the unknown, to do the "impossible," but are far too slow in adopting photographic methods. The moving picture and the microscope can see a million times quicker and smaller than the eyes. Unaided vision can recognize a two-hundredth of an inch, but not interpret it, while motions quicker than a tenth of a second run together: one cannot separate them. How, but for the microscope and photography, could we know the vast world beyond? It can show what is happening right down to the bare bones of matter and force.

Limitations of Optical Lenses

Many who read this may not be thoroughly familiar with the optics of an optical or photographic microscope, so some of the principles affecting this work will be noted briefly. In applying photography to the microscope we find certain exacting conditions and narrow limits in which to work; the laws governing numerical aperture, resolving power and wave length are inflexible.

In working with opaque objects the problem is much

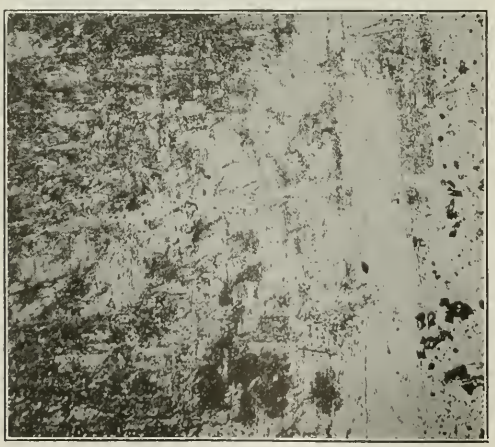

FIG. 1. FELDSPAR BY ORDINARY LIGHT. × 100
IDENTICAL AREA AS IN FIG. 2

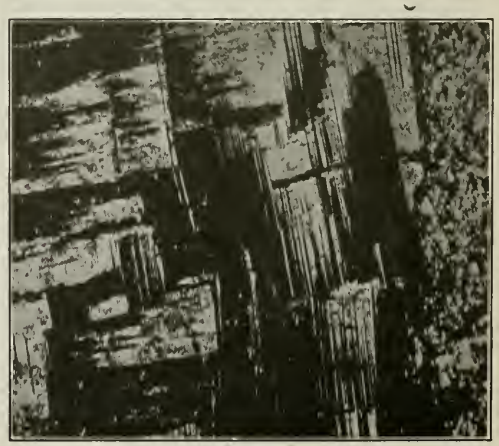

FIG. 2. FELDSPAR BY POLARIZED LIGHT, CROSSED NICHOLS. × 100

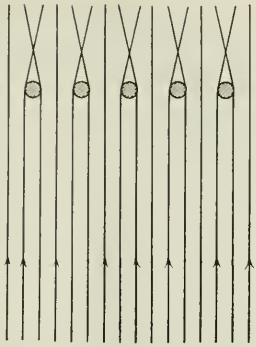

FIG. 3. EFFECT OF DIFFRACTION ON PARALLEL LIGHT

different than with transparent objects. In the latter case the illuminating system passes the light rays directly through the specimen and into the miscroscope. The resolution of the system, or the power to render visible the various parts of the object, is an important consideration, as well as the thickness and quality of specimen, glass slide and cover glass. In low power work we are able to make full use of the resolving power of the lens and it is comparatively easy to obtain

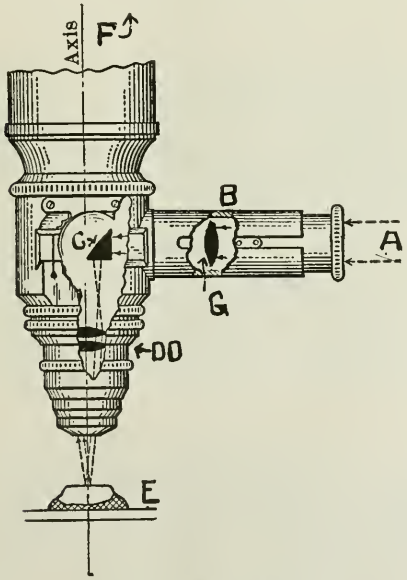

FIG. 4. PRISM ILLUMINATOR

perfect results. As we understand it, resolution may be defined as the ability of an objective to render correctly the diffraction phenomena of a subject in transmitted light. If we place a rod in a stream of water the water flows around it. If we place a rod in a beam of light some of the rays no longer travel straight but bend around the edges of the obstruction—this we call diffraction. Such opaque lines in a subject may be several thousand per inch, when the diffraction image will be confusing and if not correctly rendered will lead to misinterpretation. (Fig. 3.)

In the case of opaque objects reflected light is used, the objective acting both as condenser and objective. At first sight it appears quite impossible that the objective can transmit light in one direction to illuminate a subject and transmit in the opposite direction the image of an object so illuminated without interference. Yet in this case one is concerned mostly with

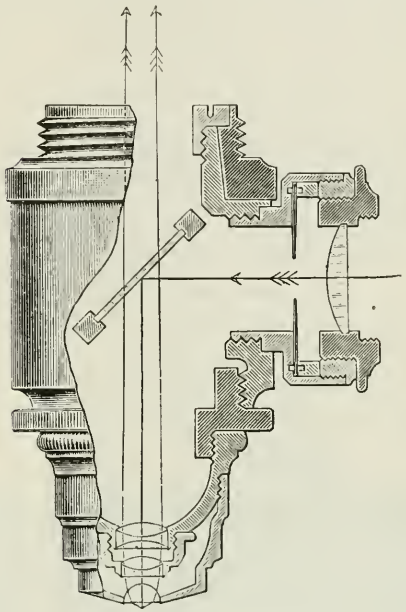

FIG. 5. PLANE GLASS REFLECTOR

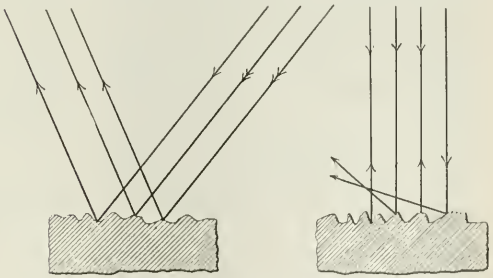
the defining power of the lens, rather than its resolution.

There is another important qualification for the microscope lenses—their correction for color. The ordinary microscope has achromatic lenses, that is to say, they are corrected for two regions of the spectrum so that there is little trouble with color fringes at low powers. A superior system of lenses is called apochromatic; these bring the three regions—red, green and blue—to a perfect focus with the image by the use of lenses of different kinds of glass, so that there are



FIGS. 6 AND 7. AT LEFT—OBLIQUE LIGHT RENDERS THE SUBJECT DARK WITH FEW BRIGHT LIGHTS, ALTERING THE APPEARANCE OF THE RELIEF. AT RIGHT—VERTICAL ILLUMINATION RENDERS BLACKS AS BLACK AND POLISHED SURFACES LIGHT

no color fringes. In using the microscope for ocular observation, color fringes, defects due to spherical aberration and lack of definition are not always serious defects, because the eye is something of a compensator and has "persistence of vision." In photography, color fringes destroy the sharpness of the image, while spherical aberration, producing different foci for central and marginal rays, permits only a portion of the subject to be clearly defined on one exposure, so the results may be not only unintelligible but misleading. The plate has no imagination, it records the facts as presented.

Illumination of Opaque Objects

To illuminate an opaque object such as a piece of polished metal, a vertical illuminator furnishes the only correct rendering, but its use does impair the optical qualities of the objective. In the customary objective for transmitted light, the lenses are mounted at varying distances by different makers, and corrected

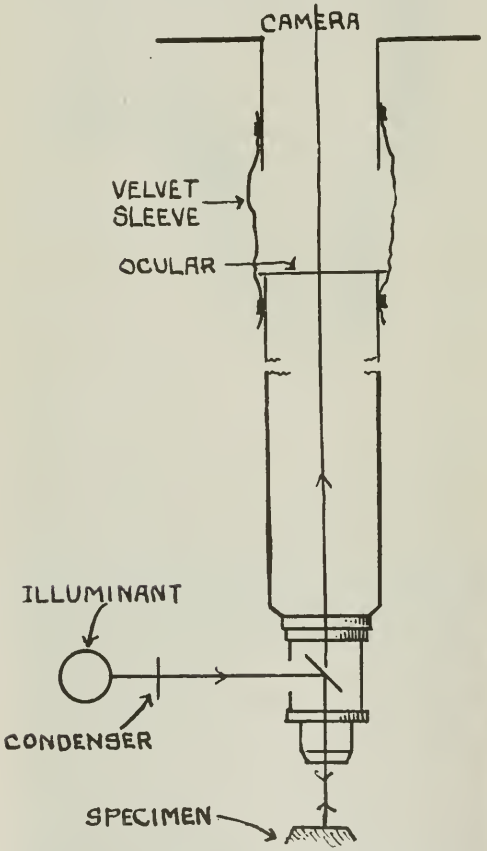


FIG. 8. ARRANGEMENT OF APPARATUS FOR MAKING MOTION PHOTO MICROGRAPHS OF OPAQUE OBJECTS

for a cover glass over the specimen. For use with the vertical illuminator the lenses must be short mounted to avoid internal reflections and uncorrected for cover glass—none being necessary.

Figs. 4 and 5 illustrate two common types of vertical

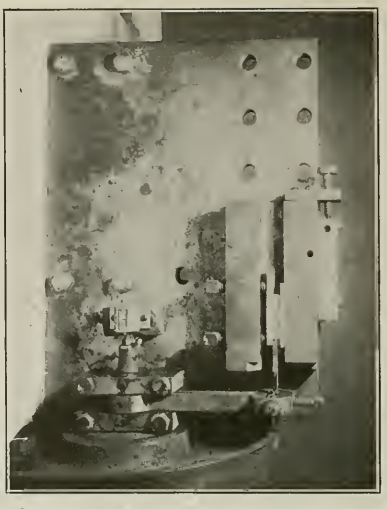

FIG. 9. STRESSING MACHINE DESIGNED BY PROF. H. F. MOORE, WITH TEST SPECIMEN IN PLACE. ROTATION OF FLYWHEEL TRANSMITS VERTICAL OSCILLATION TO THE OTHER END OF THE TEST PIECE, PRODUCING BENDING AT THE VISE

illuminators. With the plane glass reflector there is a tendency to produce a haze over the image, while with the prism there is a tendency to form a sculptured or relief image. Yet either gives satisfactory results under proper conditions.

From the illustration (Fig. 4) it is seen that the illuminant at *A* passes its light into the tube *B* (preferably in parallel rays) through the converging lens *G* which focuses the light source on the hypotenuse of the prism *C*, thence through the objective lenses *DD* which concentrate the light on the subject *E*. An image of *E* is formed by *DD* projecting it to the ocular *F* which not only magnifies the image but corrects errors of the objective.

Such illumination does not appear to be a difficult operation, yet under some conditions trying difficulties occur. For instance, it is essential that *AB* be at right angles to the microscope tube and that the lenses be clean and free from dust. (It seems quite impossible to keep dust from the lenses; it returns again and again.) The axis must be perpendicular to *E*, otherwise

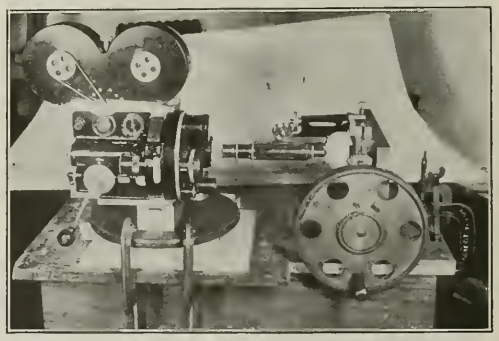

FIG. 10. ASSEMBLED APPARATUS WITHOUT VELVET SLEEVE OR ILLUMINATING DEVICE

the specimen will not appear properly illuminated. It is seen in Fig. 6 that if the light is at all oblique the reflected rays which should pass into the objective will fall outside. The relief will be changed in appearance and the object will appear but partly lighted. In Fig. 7 the light falls vertically, most of it returns to the objective and the relief appears correctly.

Illumination for Motion Picture Camera

To make motion pictures through this apparatus it is necessary to place a motion picture camera at a short distance from the ocular *F*, as shown in Fig. 8. The lenses are preferably removed, while magnification is changed by using oculars of various powers.

For motion work of this nature a flickerless light-source is necessary, as any fluctuations in illumination are recorded in the negative. The axes of light-source and of microscope must be at right angles horizontally and vertically, and the surface of the film must be at right angles to the axis of the microscope. Furthermore, all of the elements must be rigidly fixed. To comply with these conditions in a built-up apparatus requires considerable time and care. As a case at hand, some motion pictures of a wrought-iron test bar showing the mechanism of failure under alternating stresses were made for Prof. H. F. Moore of the Materials Testing Laboratory, University of Illinois, the designer of the fatigue machine (Fig. 9). I used a 400-watt gas-filled lamp of stereopticon type, the image of one filament only being employed, which was projected into the tube by the condensers of a No. 0 delineascope. An arc was found to be not only too intense but too variable in color and position. A gas-filled bulb with only one filament would be very desirable, while the Nernst or the new incandescent lamp as used for motion picture projection might answer well. It is best to absorb the heat from the light with a water cell. A prism illuminator was used with an achromatic objective and a compensating ocular, as these oculars give much better results than a Huyghenian.

Motion Microphotographs

All types of motion cameras are not readily adaptable to these special problems. Devices have been constructed for making motion pictures in various lines of research, notably at the Marey Institute in France. For my purpose I found the Bell and Howell camera an incomparable instrument. It is entirely of metal, compact and mechanically faultless. The rotating lens turret and the sliding base permit the focusing aperture to be moved to the exact position occupied by the film when recording.

As shown in Fig. 10, the camera and the stressing machine are clamped very firmly to a substantial table—a masonry pier would be more desirable—and the camera is then connected to the microscope by a black velvet sleeve to facilitate adjustments and to break the transmission of any vibration. A device for observing the action continuously by eye might be inserted but would result in some loss of definition. The microscope

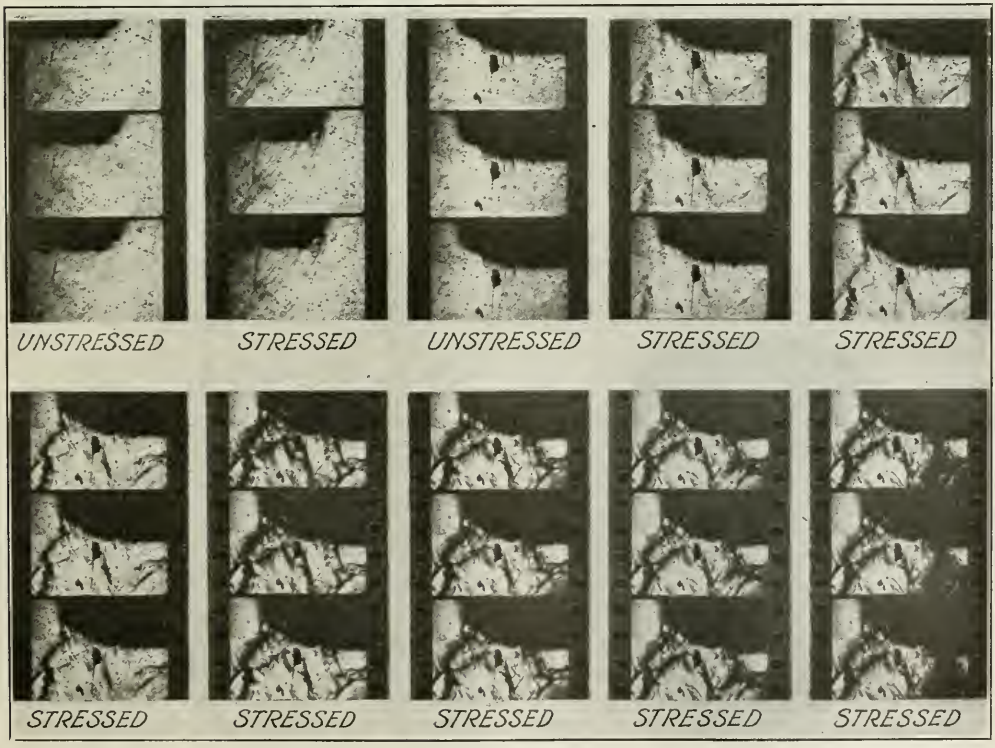

FIG. 11. MOTION PICTURES THROUGH THE MICROSCOPE. SUCCESSIVE STAGES IN REPEATED STRESS OF WROUGHT IRON. × 70

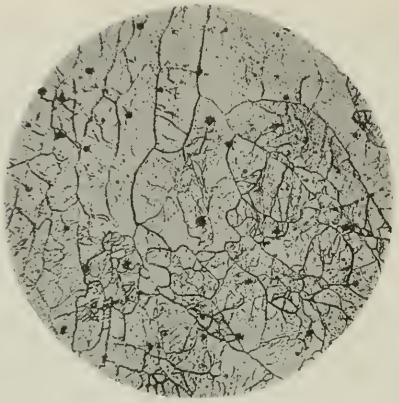

FIG. 12. STRUCTURE OF WROUGHT IRON BEFORE BEING SUBJECTED TO REPEATED BENDING STRESSES. × 200

was first focused on a polished region at the base of the shoulder, shown in Fig. 9, where the stresses will be most intense.

Photographs of metals are usually at low power—one hundred or less. In making motion pictures the magnification was even lower in order to exhibit a sufficient field for study. This leads to more difficulty, because in the low magnification, the lines made by the crystal boundaries become so narrow that it is difficult to retain them in negative and positive with enough density to project well. It is possible to improve the sharpness of the image by using deep colored screens, preferably in the blue-green, thus eliminating other colors which might form color fringes. If this is done. panchromatic film is necessary. By the accompanying table of resolving powers for transmitted light it is seen how much the working qualities of lenses are improved by increasing the numerical aperture and decreasing the wave length. Violet light is difficult to use, however, because the eye works very poorly in that region and it is quite impossible to focus the object, even with a magnifier. Sections of the film made in the present instance are shown in Fig. 11, while exposures of the same test made at higher powers with an ordinary metallographic microscope are shown for comparison in Figs. 12, 13 and 14. In the results shown here the negative was made on positive film at the normal speed of 16 pictures per second, giving an exposure of $\frac{1}{48}$ of a second, the negative film being too fast and not giving satisfactory contrast.

LIMITING RESOLUTION

Objective	N.A.	Yellow line D λ = 5896 A.U.	Green line E λ = 5269 A.U.	Violet line H_γ λ = 4341 A.U.
1½	.10	8,617	9,641	11,699
¾	.25	21,542	24,103	29,247
⅓	.6	51,700	57,846	70,193
⅛	.9	77,550	86,769	105,289
Oil immersion 1/12	1.4	120,638	134,974	163,783

The little work which I have done in this field and the consideration of other special problems lead me to think that the motion camera with and without the microscope offers a means of research the value of which we can hardly predict. The field of application is as wide as human knowledge. Processes and reactions in the natural sciences and phenomena in the physical sciences will unfold many opportunities as we search for new facts. Special apparatus has been constructed whereby consecutive exposures can be made, each in one ten-millionth of a second. With such a tool, the transmission and reaction of sound waves might be quite readily photographed in motion.

One day some one may record the passage of electrons discharged across a vacuum. We can hardly set a limit.

Where Hamlet Was

Referring to our notes under the title of "'Hamlet' with Hamlet Left Out," in our last issue, Major Charles E. Sholes, honorary chairman of the N. Y. Section of the Society of Chemical Industry, calls attention to the fact that it was not the fault of the authors that the paper on Fuels was missing. The manuscript had been mailed in ample time and was *en route*, where it rested for a considerable period along with the information that the authors, Messrs. Bacon and Hamor, were prevented by pressure of other duties from putting in personal appearance. It will appear in an early number of the Journal of the Society.

An Improved Method of Optical Glass Manufacture*

By George W. Morey

THE USUAL practice in the manufacture of optical glass consists of the following sequence of furnace operations:

The pot is carefully preheated in a small subsidiary furnace, called a pot arch; from there it is "set," or transferred to the furnace. The pot is usually set at a temperature of about 1050 deg. C., and it must be heated up to the melting temperature of the glass batch, about 1400 deg. for most glasses, before filling. The best practice is to overburn the pot before commencing the fill.

The batch, or batch mixed with cullet, is fed into the pot in several installments, until the fill is complete. The details of this process differ from plant to plant.

After the fill is complete, the glass is left undisturbed for several hours, primarily to give time for the bubbles to rise to the surface. The temperature during this period is high; in some places it is the practice to use a higher temperature for the fining operation than for the fill.

After the fining period is complete, it is customary to stir the glass by hand, intermittently; a common schedule is to hand stir for 15 minutes every two hours. This process removes the bubbles of gas adhering to the side and bottom of the pot, and helps to secure uniformity in composition.

After the period of intermittent hand stirring is complete, the glass is stirred continuously, a stirring machine being used. As a rule, soon after putting on the machine, the fire is turned off and the glass allowed to cool, stirring being continued until the pot is removed from the furnace. The operations summarized above take from two to three days in the furnace, the actual time depending on local practice. When, as is usually the case, the empty pots are preheated in pot arches, and the finish glass cooled in an appropriate subsidiary apparatus, a melting furnace will yield one pot of glass every two days.

New Schedule Doubled Production

After considerable experience in manufacturing optical glass, certain of the usual operations seemed to be inadequate or illogical, and soon after taking charge of the optical glass plant of the Spencer Lens Co. for the War Industries Board, I devised a new schedule radically different from the above, which may be called the "24-hour" process. Because of its importance in practically doubling the production of optical glass, a basic material in the manufacture of fire control instruments, the details of the process were communicated to the Military Optical Glass and Instrument Section of the War Industries Board, and were communicated by them to the other manufacturers of optical glass.

In the first place, the filling operation required modification. Melting of the batch takes place from the top downward; the upper layer sinters together, then the more easily fusible components trickle down, leaving the upper layers impoverished in the substances usually called "fluxes." This results in the surface becoming high in silica; this is proved by skimmings from both crown and flint batches, which not only showed an actual accumulation of partially dissolved quartz grains, but also had a refractive index lower than that of the rest of the glass.

Harmful Effects of Fluxes Settling to the Bottom Overlooked

The fluxes, especially lead, tend to settle to the bottom; this is proved by the dark layer always brought up when hand stirring is begun, by tests made by plunging a long iron rod into the glass and quickly withdrawing it, and by the examination of partially melted pots which have been removed from the furnace because of leaks, and broken after cooling. In the latter case, the preponderance of silica mentioned above has also been observed.

This initial inhomogeneity, it is true, is removed by the subsequent stirring operation, and this probably accounts for its harmful effects having been overlooked. One of these harmful effects, especially in flint glasses, is due to the fact that lead-rich mixtures (for example the extra-dense flints) are extremely corrosive on the pots. By the older process this lead-rich layer is allowed to lie on the bottom of the pot throughout the filling and the fining periods, both of which periods are of some hours' duration and of extremely high temperatures. This necessarily results in greatly increased pot corrosion. In addition, the impoverishment of the upper layers in fluxes increases the time required for complete solution of the batch ingredients.

Stirring During Fill the Remedy

The obvious remedy is to stir during the fill.[1] This is not feasible until the pot is a little over half full, because the stirring rod cannot be floated before this, but as soon as feasible it should be begun, and the melt should be stirred each time new batch is added. Making such a stir during the fill should diminish pot corrosion, give glass of a better quality, freer from color, striæ and stones, and should hasten the solution of the batch and thereby shorten the melting process.

After the fill is completed, the glass must be freed from bubbles of gas arising from the decomposition of carbonates and nitrates in the batch, and from the water in the batch ingredients. In some cases these volatile components comprise one-fifth of the weight of batch filled. By the old process the bubbles are mainly removed during the fining operation, the glass being kept hot and undisturbed for some time to allow the bubbles to rise to the surface. The intermittent hand stir following supplements the fining period by removing the layer of bubbles which adheres to the pot walls, and also tends to secure uniformity in composition throughout the melt.

Stirring the Logical Way to Remove Bubbles

That seemed an illogical way to secure the desired result. In the first place, common experience is that bubbles in other liquids are more rapidly removed by stirring than by quiescence. It seemed reasonable to suppose that in a pot of glass also the bubbles will be more rapidly removed by stirring. Moreover, in the usual process the glass is not homogeneous in composition until after the fining period; the upper layer is deficient in fluxes, and hence melts less rapidly than the mass of the glass. The margin in composition be-

*Read before the American Ceramic Society at Pittsburgh, Feb. 3-6, 1919.

[1] Since presenting this paper I have heard that at one time stirring during the fill was tried at the Charleroi plant of the Pittsburgh Plate Glass Co.; others doubtless have made the same attempt.

tween an unworkably viscous glass and a workable glass is a narrow one; the stirring should prevent the upper portion being deficient in fluxes and hence too viscous to permit the free passage of bubbles. It seemed a reasonable supposition, therefore, that two of the operations to which optical glass is usually subjected could be dispensed with, namely, the long fining period and the period of intermittent hand stirring. In other words, it seemed that better results could be obtained by putting on the stirring machine immediately after the fill, and stirring continuously until the glass was free from bubbles. With this modification could well be combined a hand stir during the fill, as mentioned before.

Results Prove Reasoning Good

The best test of this reasoning is the results. The new schedule was tried out on a melt of flint glass having an index of 1.617. The melt was run at the usual temperature for this glass, 1390 deg. C. Fills were made at 2-hr. intervals, the first fill being about one-third of the total batch, and on each subsequent fill the pot was heaped up with batch. As soon as possible a hand stir was made; ten hours after the first fill the stirring machine was put on; at this time there was still undissolved batch, not all quartz. The stirring machine was run at a good speed, both with a circular and with a vertical motion. After six hours the glass seemed free from bubbles; the fire was accordingly turned off and the pot cooled and removed as usual. The entire process, from the time the pot was set until the melt was out of the furnace and another pot set, was 24 hours. When the glass was examined, it proved to be of the best quality, wholly free from bubbles, of greatly improved color, and also freer from striæ than usual.

Special Schedules for Different Types of Glass

The details of the process were subsequently modified, and special schedules were worked out for the different types of glass. Following is a sample schedule, being that for a flint having $N_d = 1.617$, $\nu = 36.5$. The pot used is 26 in. high and 28 in. in diameter, inside dimensions. The time of filling in the cullet is taken as zero hour.

SCHEDULE FOR MF$_2$ GLASS
Run at 1390 Deg. C.

Hr.	
0:00	Add cullet
1:00	Fill pot three-quarter full of batch
2:30	Fill pot with batch
4:00	Hand stir; fill pot with batch
5:30	Hand stir; fill pot with batch
7:00	Hand stir; fill pot with batch
7:30	Stirring machine on
15:00	Gas off

When cooled to the proper temperature the pot of glass is removed from the furnace, and slowly cooled in a pot arch. A new pot is set into the furnace, and given a preliminary burning, so that in 24 hours all is ready for another melt.

It may be well to emphasize one point of difference between the longer process and the 24-hr. process. In the former the melt, often with an unduly corrosive layer on the bottom, remained in contact with the hot pot for from 20 to 30 hours from the time the last fill was made until the gas was turned off; in the 24-hr. process the corresponding period of maximum corrosive action is 5 or 6 hours. As the majority of the contamination of glass, with our present raw materials, comes from the pot, the superiority of the newer process is obvious. Better color results from smaller pot contamination, as well as a greater freedom from striæ, less trouble from stones and less pot breakage.

Process Proving a Success

The first experimental pot of glass made by the 24-hr. process proved a complete success. Since that time some 350 pots of glass have been made by the shorter schedule. They comprise practically all types of glass; flints, from an extra-dense flint with refractive index of 1.76 to an extra light flint with index of 1.55; soft crowns and ordinary crowns of three different types; several types of borosilicate crown; several barium crowns, both light and dense, and several baryta flints, ranging from a light baryta flint with index 1.56 to a dense baryta flint, index 1.62. Without exception the new process has produced a better glass than the old, with a doubling of production and correspondingly lower cost.

Some Wild Engineering I Have Known*

By David Wesson

MANY, if not most, of the troubles in this world come from lack of knowledge of the natural laws and their proper application to practical problems. The theories of practical men are often examples of the old saying that a little knowledge is a dangerous thing. It sometimes leads to wild conclusions, as in the case of the Irish foreman who was seen thoughtfully studying a light footbridge between two buildings about 60 feet apart. Resting on the bridge was a three inch steam pipe. On being asked what the matter was, the foreman said, "That pipe carries 80 pounds of steam to the inch and 960 pounds to the foot, and the bridge is 60 feet long, which figures to 57,600 pounds, and I'm after thinking that must be an awful strong bridge."

The above incident happened before the days of chemical engineering and the chemist who worked out from his laboratory into the plant had to depend on the plant engineer to put his ideas into practice. In those days the plant engineer was more likely than not a man who had graduated from the machine shop and engine room, with a very hazy idea of physics but a strong reliance on his practical experience and ability to guess. When such a man and a chemist started to design a plant it was often a case of the blind leading the blind, and things were created which sometimes worked and sometimes did not. Difficulties arising from such causes naturally set the scientific minds of the chemists to looking into the causes, and after a proper diagnosis it was comparatively easy for the chemist to design what was needed and let the mechanic do the actual construction work. This, in the writer's opinion, was the genesis of the chemical engineer.

The writer had the privilege in 1887 of visiting most of the pioneer cotton oil refineries of the country. They were built by mechanics, not chemists, and varied greatly in design and construction. One plant was equipped with cylindrical tanks with flat bottoms and agitated with paddles revolving on a horizontal axis passing

*Extract from a paper read at the Chicago meeting of the American Institute of Chemical Engineers on Jan. 17, 1919.

through the walls of the tank. The soap stock formed in the process of refining was drawn off as much as possible from the flat bottom after each refining, and what was left went into the next batch.

Weird Refinery Practices

Another refinery showed with pride a large tank made to refine 400 barrels at one batch, but they never worked it more than half full because the heating coil was too small to heat the oil rapidly enough, though sufficiently large to condense all the steam from the entire boiler plant.

A refinery in New England noted for the fine quality of its oil did all its work with 1½-in. pipe lines and kept small pumps going 24 hours per day to handle comparatively small quantities of oil.

About 1888 or 1889 a new company put up five large oil mills which were equipped with Abendroth Root high pressure water-tube boilers and Brotherhood engines sprinkled about the large barnlike mills. Pipe covering and insulation were considered useless luxuries, and naturally the mills did not operate very successfully. The engines were natural steam hogs, and the overworked boilers were always breaking down. The management had to change the type of boilers and install central power plants with Corliss engines before their mills were put on a paying basis.

Funny Things Seen in Pipe Lines

In running pipe lines funny things happen sometimes. I remember seeing in a certain plant in Germany a pipe bent on a beautiful curve on a 3-ft. radius and connected into the sharpest kind of a right angled elbow at one end of the bend.

In a plant at Memphis some years ago a filter press was located in the top of a refinery, and the 4-in. pipe line to carry off the filtered oil to storage tanks 100 ft. distant was run by the engineer in charge with a 4-ft. drop straight to the storage tanks. When the filter pump was started up the pipe line was found too small to carry off the oil and the pan overflowed. Of course the plant was practically tied up till a chemist arrived on the scene and ordered the pipe line dropped to a horizontal position and connected with a 3-ft. vertical pipe from the filter trough. In the first case a straight line, though the shortest distance between two points, did not have more than a 6 in. of head to force the oil through it, while in the second case there was a little over 3 ft. of head and the oil ran off freely.

Engineers who should know better design large tanks to be heated by steam jackets instead of suitable coils. They do not realize that it is impossible to get sufficient heating surface in jackets, nor do they consider the danger in working with jackets at high pressure.

To Prevent Fires—Don't Erect Buildings

In a Southern city some years ago there was a plant engaged in distilling rosin to make rosin oils. Fires were frequent, and the cheap frame buildings over the stills were burned down. Finally the brilliant plan was evolved of doing the work out of doors. After that they had no more conflagrations but in cold and rainy weather the stills did not work very well. Some neighboring manufacturers engaged in distilling fatty acids tried the same scheme. The stills were out of doors, the condensers were in a fireproof house. There were no fire damages to be paid for by the insurance companies, but the quantities of fuel used in cold and wet weather, the smaller amount of fat converted into tar, the lost time and repairs soon amounted to several times more than a house over the stills, which was eventually built during the absence of the general manager, with the result that the plant became more profitable shortly afterward.

A mistake frequently observed is the design of tanks to be used under vacuum with too light materials, with the result that they collapse when put in use.

All of us looking back over our experiences can think of many other examples of wild engineering leading to more or less disastrous results. The foregoing cases are sufficient to illustrate the ease with which people who should know better are apt to transgress physical laws, which are capable of demonstration. The results, while bad enough, are infinitesimal as compared with those obtained by some of our elected statesmen, who often from ignorance and often for the sake of votes take great liberty with social and economic laws and commit social and economical engineering atrocities. The law of supply and demand, for example, is as immutable as the law of gravitation, but how often have we seen it defied by Government officials. We can hold back the flood of a watercourse for a time by constructing a suitable dam, but sooner or later if the water supplies keep increasing the dam will either overflow or be carried away and destruction will result.

Wild "Engineering" by Legislators

The prices of labor and materials of all sorts can be maintained at unnatural levels by war-time restrictions, as we have all seen, but the moment war-time conditions remove the prop from the dam, unless suitable channels are constructed to reduce gradually and safely the pent-up level of the flood, disaster is bound to ensue.

When one sees legislators passing laws preventing the formation of large industrial and transportation aggregates, it would seem that a lesson might be taken from the courtiers of King Canute, who imagined that a word from the governing powers would prevent the rising of the tide when they placed the King on his throne upon the beach.

Co-operation Needed

The lesson we must all learn from the war and the period preceding it is that the day of co-operation is at hand. By the co-operation of nations the common enemy was defeated. By the co-operation of railroads and steamship lines in our own country transportation was speeded up. By the co-operation of industries production was increased enormously. Now that the war is over the need of co-operation is greater than ever. The so-called conflicting interests of labor and capital must be caused to co-operate in such a manner that our complex social fabric shall have all parts working in harmonious unison to make the most of our natural resources and create again the enormous wealth destroyed by the war. This is the problem we all have before us and to which we will have to devote our best energies, both as worthy citizens of our great country and as members of our profession of chemical engineers.

A Proposed Metallurgical Process for the Treatment of Vanadinite for the Recovery of Lead and Vanadium*

Vanadinite Concentrate Is Fluxed and Reduced With Soda Ash, Caustic and Carbon, Giving Metallic Lead—Slag Is Elutriated, Si and Mo Precipitated With Lime—Vanadium Pentoxide 86 Per Cent Yield With Sulphuric Acid

By J. E. CONLEY

THE supply of practically all of the vanadium used at the present time in the United States comes either from the patronite of Peru, largely controlled by the American Vanadium Co. of Pittsburgh, or from the roscoelite found near Newmire, Colo., controlled by the Primos Chemical Co. Considerable vanadium is also produced from the carnotite ores of Utah and Colorado, as a by-product in the production of radium. Practically no vanadium is obtained from other vanadium ores.

Attention has been called repeatedly to the vanadinite deposits found in the United States, particularly those of Arizona and New Mexico, but thus far very little progress has been made in developing these deposits as a source of vanadium. Some time in 1910, the Vanadium Mines Co., having acquired some vanadinite deposits in Sierra County, New Mexico, erected a mill near the mine, and a reduction plant near Cutter for the commercial treatment of the ore. A little later, however, the plant was dismantled and the mines abandoned. As far as known, this is practically the only attempt ever made in this country for the industrial treatment of vanadinite.

During the last two years a 50-ton mill has been built at Kelvin, Ariz., by the U. S. Vanadium Development Co., which planned to use the Bryan process of concentration[1]. Recently, however, this property has been leased by the Allied Metals Corporation of Denver.

Plenty of evidence is available to show that vanadinite ores have been rather extensively mined and treated at Santa Marta, Spain.

In addition to these occurrences, vanadinite is known to be found in commercial quantities in Nevada, California, and several places in Mexico, as well as in Argentina.

The concentration of vanadinite is not a difficult process unless found with other very heavy minerals. The recovery of the vanadium is quite satisfactory, providing an appreciable amount does not occur as the pentoxide. Very frequently vanadium minerals show a portion of the vanadium either as the oxide, or as compounds with calcium, copper, etc., and occur in the form of a fine powder. In these cases the recovery in concentration is considerably lowered by the tendency of the powder toward sliming. The present paper, however, is not so much concerned with the concentration of vanadinite as in the treatment of vanadinite after concentration. This phase of the work was deemed sufficiently important to undertake the investigation of the metallurgy of vanadinite for the purpose of selecting and recommending a procedure.

The ore used in these experiments was in the form of concentrates obtained from Mr. E. Payne Palmer of Phoenix, Ariz., and came originally from the property near Ray Junction, Ariz., now leased by the Allied Metals Corporation. An examination of this concentrate showed it to consist largely of vanadinite and quartz, with small amounts of iron silicates, galena, calcite and wulfenite. About 90 per cent of the ore would readily pass a 30-mesh sieve. An analysis of the samples used showed:

ANALYSIS OF CONCENTRATES

	Per Cent		Per Cent
PbO	53.88	CaO	2.10
V_2O_5	12.60	Insoluble	16.93
MoO_3	1.98	Loss on ignition	2.52
Fe_2O_3	4.26	Undetermined	4.52
Al_2O_3	1.21		

From these figures it is seen that the ore is of high grade and that the recovery of the lead is an important consideration.

Preliminary Methods Tried for the Extraction of the Values

Several methods of procedure were used on these concentrates, either by trying to apply treatments already being successfully used on other vanadium minerals, or by any methods which presented possibilities. The earlier experiments were made for the purpose of extracting the vanadium, but it is seen that the treatment should be materially influenced by the lead present. Any method not adapted to the recovery of this lead must certainly be unsatisfactory.

An outline of the methods tried which were found unsatisfactory is given in Table I.

TABLE I—METHODS TRIED ON VANADINITE CONCENTRATES

Treatment	Reagents Used	Results
1. Alkaline leach...	Strong solutions of caustic and sodium carbonate	Less than 1 per cent of vanadium soluble
2. Acid leach.....	Dilute and concentrated sulphuric acid	Poor extractions
3. Acid leach.....	Dilute and concentrated hydrochloric acid	Poor extractions with permissible quantity of acid
4. Fusion.....	Niter cake; niter cake and charcoal	45 per cent extracted with niter cake; increased to 85 per cent by addition of charcoal
5. Fusion.....	Soda ash and sodium nitrate	Very fluid slags, but poor extractions

None of the methods given in Table I was found to give sufficiently satisfactory recoveries to be recommended as a process for treating the concentrates. As can be seen, none of the methods is adapted to a direct recovery of the lead.

Fusion With Soda Ash and Caustic Soda

Innumerable fusions were made with the concentrates by using soda ash, caustic soda, and mixtures of both, with the addition of charcoal. A mixture of soda

*Published by permission of the Director of the Bureau of Mines.

[1] *Eng. & Min. Jour.*, Vol. 107, No. 3, p. 149.

ash and caustic soda was eventually found that could be recommended as quite satisfactory for good recoveries at reasonable costs. The results of these fusions will be given together with the amounts of flux required.

Fusion Experiments With Caustic Soda and Soda Ash

The fusion of vanadinite with these fluxes, using charcoal as a reducing agent, favors in a measure the extraction of the lead. The lead requires a reducing fusion, while the vanadium is best extracted in an oxidizing fusion. It is the highest oxide of vanadium, the pentoxide, which possesses acidic properties and which is used in reacting with the bases to form soluble sodium vanadate. Conditions of the fusion, therefore, are favorable for the formation of the lower oxides which possess basic properties. This condition is overcome, however, by heating the slag to obtain oxidation, or by the addition of a small amount of a suitable oxidizing agent, such as niter, after the removal of the lead. Higher extractions are always secured if these precautions are taken.

Reference to Table II will show the results obtained by varying the proportions and amounts of flux used.

TABLE II.

No. of Run	Ore Used (Grams)	Na_2CO_3 (Grams)	NaOH (Grams)	Charcoal (Grams)	Per Cent V_2O_5	Extraction. Pb

In these fusions, caustic soda was found far more efficient than soda ash in rendering the vanadium water-soluble. Soda ash has been actually used, both at Cutter, N. M., and more successfully upon the vanadinite ores at Santa Marta, Spain. These ores, containing from 12 to 14 per cent vanadium pentoxide and about 50 per cent lead, very nearly correspond to the concentrates used in these experiments. It was found, however, that in any fusion in which the amount of caustic was less than 20 per cent of the weight of the ore, the vanadium extraction dropped rapidly, an objection which was but partly overcome by increasing the amount of soda ash. By reference to the table, it is seen that a sample fused with 30 per cent of its weight of caustic yielded only 9 per cent of its vanadium, but when the caustic was raised to 40 per cent, the extraction was 94 per cent.

In all the experiments made, the caustic soda, although higher priced, was far more satisfactory, both for recovery of lead and vanadium. Caustic soda was expected to give a poorer lead recovery than the soda ash, but it was actually found to give better. This can probably be explained by the fact that a more fluid slag is obtained, which facilitates the settling of the lead.

The prediction that the proportions of flux recommended will work out satisfactorily on a large scale is borne out by a run made on a 50-lb. sample. Fifty lb. of ore fused with 20 lb. of caustic, 5 lb. of soda ash and 2 lb. of coal yielded 23½ lb. of lead and gave a vanadium extraction of 89.6 per cent.

The actual literature on the treatment of vanadium ores is very meager and incomplete. Most of the information on the treatment of the ores is kept secret, and the small amount made public is carefully covered by patents. This is true of vanadium more than any other of the rare metals.

In the small amount of literature really available on the treatment of the vanadium ores, special emphasis is given to the treatment of the ores. Practically no emphasis is laid upon the recovery of the vanadium from the solutions obtained. This part of the subject is usually dismissed with some such statement as, "The vanadium may be recovered from solution by any of the well-known methods."

The recovery of the vanadium from solution as a high-grade product by an efficient and economical method is by no means the less important part of the process.

In these experiments for the recovery of the vanadium from solution, three procedures were used

1. The direct precipitation of the vanadium from the alkaline solution obtained by leaching the slag after removal of the lead. The precipitants used were:
   (a) Calcium chloride.
   (b) Chloride of lime and slaked lime.
   (c) Slaked lime.
   (d) Calcium sulphate.
   (e) Barium hydroxide and chloride.
2. Evaporation of solution to dryness in the presence of an excess of acid. The acids used were:
   (a) Sulphuric.
   (b) Nitric.
   (c) Hydrochloric.
3. The precipitation of the vanadium as the pentoxide by boiling in sulphuric acid solution.

Experiments on the Precipitation of Vanadium From Alkaline Solution

In these experiments preference was shown the common calcium salts. This was due to the cheapness of the reagents, as well as to the properties of the resulting product, namely, calcium vanadate. Many of the vanadates show a more or less tendency to form colloidal precipitates which filter very poorly. This tendency is less marked with calcium vanadate, so that a product which filters readily and permits washing is usually obtained.

The precipitation of the vanadium as iron vanadate necessitates the neutralization of the solution, as iron vanadate is best precipitated in a slightly acid solution. This was confirmed by some experiments made on the recovery of vanadium from a sulphuric acid solution obtained in treating cuprodescloizite. This precipitation, however, is being satisfactorily used at the present time and could, no doubt, be applied to this ore. This treatment is not so well adapted to the procedure adopted and to be later recommended.

Complete precipitation of the vanadium was obtained by using an excess of calcium chloride, barium chloride and calcium sulphate. With all three of these precipitants, all of the vanadium is not removed until the solution is made neutral. The principal objection to these reagents is that a large portion of the molybdenum is also precipitated simultaneously, since calcium molybdate is precipitated in a neutral solution. Complete precipitation was not obtained with a large excess of chloride of lime.

Both slaked lime and barium hydroxide precipitated the vanadium readily. Since both of these reagents increased instead of decreased the alkalinity, the result-

ing products were practically free from molybdenum. This is an important point in connection with results obtained later, since more or less wulfenite always occurs with vanadinite ores. Calcium sulphate precipitates some of the molybdenum, but only a small portion of that precipitated by either calcium or barium chlorides.

The highest grade of calcium vanadate that could be consistently maintained, and at the same time secure a satisfactory recovery, was about 16 per cent vanadium pentoxide. The grade of barium vanadate obtained from the same solution was a little better, some of the samples running as high at 21.5 per cent vanadium pentoxide. The use of barium chloride as a precipitant was not considered desirable in a commercial process.

Precipitation by Slaked Lime

The procedure followed in the precipitation of the vanadium by the slaked lime was as follows:

The alkaline solution containing the vanadium was heated almost to boiling and a thick emulsion of lime added. The mixture was then boiled and stirred frequently. This procedure was continued with the addition of more lime from time to time until the liquor showed that all of the vanadium had been precipitated. The alkalinity of the liquor is found to be increased by this treatment—a fact which assists in keeping the molybdenum in solution.

No special alkalinity was necessary or desirable for the precipitation of the vanadium, as some of the liquors after precipitation of the vanadium varied in alkalinity from an equivalent of 27.4 to 73.4 g. of sodium hydroxide per liter.

An approximate idea of the amount of lime required to precipitate the vanadium is best obtained by adding lime with the object of making a 16 per cent product, taking into consideration the fact that a portion of the silica and all of the carbonate present are also precipitated. All attempts to use less than this amount and to secure a better product by increasing the time of boiling, failed. In most of these cases, the resulting product was found to run from 15 to 17 per cent V_2O_5, and only a partial recovery was effected.

A run was made to determine the feasibility of using the 16 per cent calcium vanadate directly in the electric furnace for the preparation of ferrovanadium.

A ferrovanadium containing 38 per cent metallic vanadium was obtained. The loss of vanadium in the slag was extremely low, so that a good recovery was secured. The impurities in the ferrovanadium were all below the permissible amounts, with the exception of carbon, which can be controlled by more careful manipulation. Taken as a whole, the experiment was quite satisfactory in that both a high-grade alloy and a good recovery of vanadium were obtained.

The run would indicate that the product could be used without further treatment for the production of the ferrovanadium.

Attempts to Improve Grade of Calcium Vanadate

To be commercially satisfactory, the vanadium pentoxide content of calcium vanadate must be from 25 to 30 per cent. An attempt was made to raise the grade of the first product up to these figures by igniting the first product and using again for precipitating a new lot of alkaline solution. The ignition itself, which decomposed the hydrate and carbonate, raised the percentage from 16 to 18. The grade of the product obtained by using the first calcium vanadate instead of lime yielded a 25 per cent calcium vanadate, which was raised to 26 per cent on ignition. Thus it is seen that a product just on the lower limit of the commercial product was secured. A third precipitation, by using the second product, only raised the grade by an additional 1 per cent. This scheme can be applied for obtaining a commercially satisfactory product at what would seem a very reasonable cost. Two precipitations seem to be all that could be advantageously used.

Neutralizing Alkaline Solution With Excess of Acid and Evaporating to Dryness

An attempt was made to obtain the vanadium as the oxide by adding only sufficient acid to insure a slight excess and then evaporating to dryness. The soluble salts were leached out with water, leaving behind the crude V_2O_5. The common mineral acids, nitric, hydrochloric and sulphuric, were used.

The chief difficulty in this scheme was to obtain a good recovery with the small amounts of acid commercially possible. Another objection is the interference of the silica, which is simultaneously rendered insoluble. A larger portion of the molybdenum is also obtained, which is objectionable if the vanadium is to be used for steel.

The most promising results obtained by this method were secured by neutralizing with sulphuric and adding nitric acid for the excess. By this procedure a 92 per cent recovery of the vanadium in solution was obtained. The resulting product showed 66.8 per cent V_2O_5. The amount of nitric acid used, however, was too great to be satisfactory. The expense involved in evaporating the solution to dryness, the amount of acid required, and the contamination of the resulting product with molybdic oxide and silica are the principal objections to this procedure.

Precipitation of Vanadium Pentoxide by Boiling in Acid Solution

This method of recovering the vanadium from solution was considered the most feasible, so that considerable time and care were used in working out the conditions best suited for a good recovery of a high-grade product.

In the early experiments, it was hoped that by simply taking the alkaline solution and adding sufficient acid to make the desired concentration, the vanadium would be readily precipitated by boiling. In the attempt to carry this out, serious difficulties were encountered. Some trouble was encountered from the tendency of the silica to separate out during the neutralization. The difficulty, however, was easily overcome by diluting the alkaline solution to such an extent that after neutralization with acid the concentration would be about 10 g. per liter. It was considered that this concentration could be easily maintained on a large scale. The possibility of treating the alkaline solution to remove the silica was also considered, but the silica was found to carry down a considerable amount of vanadium. This removal had to be done upon the alkaline side and, therefore, under conditions favorable for the precipitation of many vanadates. The trouble from the silica was finally eliminated by diluting the alkaline solution and then adding to the acid, so that the resulting mixture was always on the acid side. These conditions are more favorable

for holding the silica and vanadium in solution, since it is unnecessary to pass through the neutral point to get the desired acidity.

Preference Given to Sulphuric Acid

Preference was given sulphuric acid, although a few experiments were made with nitric and hydrochloric acids. A series of runs were made with a gradually increasing acid concentration to determine the acidity best suited for the maximum recovery. The results obtained may be seen by reference to Curve I of Fig. 1.

The precipitation of the vanadium depends upon the formation of pyrovanadic acid ($H_4V_2O_7$), which is a brownish precipitate very similar to ferric hydroxide. This compound forms only in extremely dilute acid solutions when sulphuric acid is used. The experiments were then made to determine the acidity most favorable for the formation of the pyrovanadic acid, which separates out readily on boiling. Low acidities favor the formation of metal vanadates, and high acidity favors the formation of vanadium sulphates,

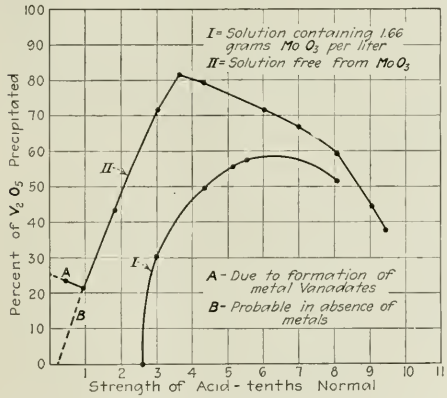

FIG. 1. CURVES SHOWING AMOUNT OF V_2O_5 PRECIPITATED BY BOILING IN SULPHURIC ACID SOLUTION 10 G. OF V_2O_5 PER LITER

which are soluble and are not thrown out of solution by boiling.

Curve I of Fig. 1 shows the results secured by using the alkaline solution obtained by leaching the slag from the fusion. This solution contains, after acidifying, silica, molybdenum and sodium sulphate as the principal impurities. No precipitation of pyrovanadic acid was obtained until the acidity became about 0.25 N, at which point precipitation began. The amount precipitated increased up to a concentration of 0.5 to 0.6 N and then decreased. The maximum recovery could not be raised above about 58 per cent. Even the addition of oxidizing agents failed to materially increase the recovery.

A synthetic solution of vanadium prepared by dissolving some pentoxide in a sodium carbonate solution showed very different results. Precipitations began at a much lower acidity and increased rapidly until a concentration of from 0.2 to 0.3 N gave a 90 per cent precipitation.

Results showed that some impurity present in the alkaline solution was responsible for the trouble. The principal impurities, silica and sodium sulphate, were successively eliminated as possibilities until some molybdic oxide was added to a synthetic sodium carbonate-pentoxide solution and an attempt made to precipitate the vanadium as before. Results obtained were:

No. of Test	Grams V_2O_5 per Liter	Acidity of Sol.	Ratio $MoO_3 : V_2O_5$	Per Cent Precipitation
1	10	3/10 N	0	87.3
2	10	3/10 N	1:6	35.1
3	10	5/10 N	0	86.9
4	10	5/10 N	1:6	65.3

The silica and sodium sulphates were found to retard slightly the precipitation of the vanadium, but the real interfering agent was the molybdenum present in a ratio to the vanadium of approximately 1 to 6, as shown in the table. The interference can be explained only by the possibility of the formation of certain soluble molybdenum-vanadium complexes. A scheme for eliminating the molybdenum was then necessary. The use of hydrogen sulphide was considered, but the precipitation of molybdenum as the sulphide is tedious and incomplete unless done under pressure. As a matter of fact, it is really a difficult analytical procedure. Another more serious objection to the use of hydrogen sulphide is that it quite readily reduces the vanadium to the tetroxide, which does not favor subsequent precipitation as the pentoxide.

The Method Recommended

The method recommended for eliminating the molybdenum is as follows:

As will be remembered, under the precipitation of the vanadium from the alkaline solution by the use of lime, it was found that the resulting calcium vanadate con-

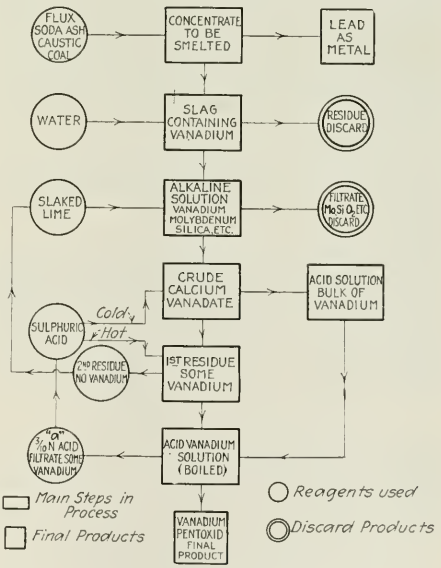

FIG. 2. DIAGRAM OF PROCESS

tained only a trace of molybdenum. This scheme was then used to dodge the molybdenum. The calcium vanadate was made by treating the alkaline solution with lime and then dissolving in sulphuric acid and throwing the vanadium out by boiling.

Curve II of Fig. 1 shows the results attained from a solution obtained in this manner. The recovery is a little lower than that from the synthetic sodium carbonate solution, but much higher than that from the alkaline solution.

The actual outline of the process finally recommended for the treatment of vanadinite concentrates is given in Fig. 2. Each ton of concentrates is smelted with 800 lb. of caustic soda, 200 lb. of soda ash, together with sufficient coal or coke to reduce the lead. The slag is then taken through the steps indicated to produce the high-grade vanadium pentoxide as a final product.

RESULTS OBTAINED ON 50 POUNDS OF ORE

Weigbt of ore	50.0 lb.
Weight of caustic soda	20.0 lb.
Weight of soda asb	5.0 lb.
Weight of coal	3.0 lb.
Weight of lead recovered	23.5 lb.
Percentage lead recovered	93.2
Weigbt of slag recovered	42.0 lb.
Percentage of vanadium extracted	89.6
Percentage of vanadium recovered as calcium vanadate	89.6
Percentage of V_2O_5 in calcium vanadate after drying	13.64
Percentage of V_2O_5 in calcium vanadate after ignition	15.90
Percentage of V_2O_5 in final product	86.6

The actual amount of sulphuric acid consumed in dissolving the calcium vanadate was not determined on this run, since it is necessary to make a number of successive runs to determine the acid consumption. Tests were made, however, on smaller lots, and it was found that about 60 per cent as much acid as calcium vanadate would be required. Assuming a 16 per cent calcium vanadate, it would require about 4 lb. of 60 deg. B. sulphuric for each pound of vanadium pentoxide, i.e., for chemical alone it would cost only about four or five cents per pound of vanadium pentoxide.

The grade of the final vanadium pentoxide prepared by this treatment varies from 85 to 90 per cent V_2O_5. The recovery is quite satisfactory, since it is maintained at the same level as the actual recovery of the vanadium from the slag. The only solution discarded, excepting as the volume of the solution after precipitation of V_2O_5 becomes too great, is the filtrate from the precipitation of the calcium vanadate. The actual acid consumption is large at the beginning of the cycle, since the excess of lime must be converted to sulphate along with the calcium vanadate; but when the calcium sulphate is used, very little acid is required to dissolve the calcium vanadate.

Care must be taken when the $CaSO_4$ is used to precipitate the vanadium, since the tendency of molybdenum to precipitate with $CaSO_4$ is much more pronounced than with CaO. Precipitation is only complete with $CaSO_4$ when the alkaline solution becomes neutral —a fact which accounts for the tendency of molybdenum to separate out also. A little care, however, avoids the precipitation of much of the molybdenum.

ESTIMATE ON COSTS OF TREATMENT
Per Ton of Ore

800 lb. caustic soda at $4.30 per cwt	$34.40
200 lb. soda ash at $2.90 per cwt	5.80
900 lb. 60° B. sulphuric acid at $16.00 per ton	7.20
200 lb. lime at $25.00 per ton	2.50
100 lb. coal at $2.75 per ton	.15
Cost for chemical treatment, labor	15.00
Total cost of treatment	$65.05

VALUE OF PRODUCTS AT PRESENT MARKET PRICES

930 lb. lead at $5.00 per cwt	$46.50
225 lb. vanadium pentoxide, 85-90 per cent, at $1.20 per pound	266.00
Total value of products	$312.50

To the above cost of treatment must be added the costs of mining, milling and concentrating, which are extremely variable factors, depending upon the location and facilities for mining. It would seem though that the difference between the value of the products and the costs of treatment would allow an attractive margin for the production of the concentrates.

The author wishes to gratefully acknowledge the many helpful suggestions received from Dr. S. C. Lind of the Rocky Mountain Station of the Bureau of Mines, under whose direction this work was carried on.

Golden, Colo.

Japanese Industrial Notes

THE Oriental Steel Manufacturing Co., Ltd., is making rapid progress. The smelting furnace ordered from the United States has arrived at the Tobata (Kyushu) works. When it has been installed, it is expected to have a capacity of 150 tons of iron per day.

Overproduction of Pig Iron

Japanese iron producers are now suffering from the inactivity of the iron markets due to the sudden ending of the war. The question of making an adjustment in prices has recently been officially decided. At first they intended to sell 50,000 tons of pig iron to the government. But this proposal was not accepted and the government purchase was settled limited to 13,900 tons. The sellers of iron being dissatisfied with the above amount, a further purchase of 2400 tons was made. There remains 33,700 tons unsold, and the producers are now looking forward for a third government purchase. It is said that this will by no means bring relief to the present troubled conditions of the Nippon ironmongers, unless the output is limited by the side of iron producers.

Fluctuations in the Wages of Artisans

The wages of artisans which have advanced more than 100 per cent are: Soy brewers, brick layers, Japanese cloth tailors, paper hangers, male servants, Japanese clog makers, saddlers, shipbuilders, gold and silver smiths, joiners. From 50 to 100 per cent: Coolies, gardeners, painters, sawyers, machinists, paper makers, founders, roofers. Up to 50 per cent: Plasterers, smiths, carriage builders, fishermen, confectioners, type compositors, foreign style tailors, stone masons, dyers.

Phosphate Rock

Manufacturers of phosphate fertilizers recently held a meeting at the Nihonbashi Club, Tokyo. The allocations of the following concerns were decided: Dai Nippon Artificial Fertilizer Co., Kanto Sanso Co., Nippon Fertilizer Co., Sumitomo Fertilizer Manufacturing Co., Taki Fertilizer Works, Osaka Chemical Works, Sakai Sulphuric Acid Manufacturing Co., Niigata Sulphuric Acid Manufacturing Co., Kokuriku Artificial Fertilizer Co.

Japanese Society of Chemical Industry

Japanese Society of Chemical Industry (in Japanese, Kagaku Kogyo Kyokwai) has recently been organized by eminent chemists under the auspices of Viscount Kiyoura to give an impluse to the chemical industry.

Japanese-American Syndicate for Manufacturing Aluminium

The problem of establishing a new co-operative concern under Japanese-American capital is now making great headway. The capital is said to be 10,000,000 yen and the object of the concern is to establish an aluminium manufacturing plant in Fushiki harbor, Toyama Prefecture, with the hydraulic power of the river Jintsu. The privilege of using the water for generating hydro-electric power is being arranged with Mr. Inoue, Governor of Toyama Prefecture.

Fundamental Principles to Be Considered in the Heat Treatment of Steel

Notes Recording Some of the Fundamental Principles Which a Metallurgist Should Use as a Check-List When Engaged in an Investigation of Heat Treatment, Selection of Metal, Furnaces, Heating and Quenching Practice, Pyrometry, and Physical Tests

By R. A. HAYWARD
District Inspection Metallurgist, Rochester District Ordnance Office

HEAT treatment of steel is entirely for quality, and in no case should quantity of production or cost of materials be allowed to influence a metallurgist in heat treating a given steel in an improper manner. If anything at all is done, it should be heat treated so as to give the best properties obtainable from that steel and not simply properties which will pass the minimum specifications.

There are three general types of heat treatment:

First, one type is known as softening. Within this branch come the two processes known as normalizing and annealing. Normalizing means heating the steel to a temperature exceeding its upper critical range and allowing it to cool freely in the air. The maximum temperature shall be maintained for about fifteen minutes and should exceed the upper limit of the critical range by at least 50 deg. Annealing means heating the steel above the upper critical range and allowing it to cool very slowly, such as cooling it in the furnace in lime, mica or similar non-conductive material. The object of these two processes is to remove all stresses which have been placed in the steel by previous working, and to refine the crystalline structure. In general, steel will respond more readily to hardening if it is previously subjected to a softening treatment.

The second general type of treatment is known as hardening. This means heating the steel above the upper critical range by about 50 deg. to 100 deg. and quenching in a suitable fluid, such as water, brine or oil.

The third type of treatment is tempering or drawing. Tempering means heating the steel below the critical range with the object of reducing the hardness, or increasing the toughness to a greater or less extent. This operation may be followed either by slow cooling or by water quenching without materially affecting the final results.

It is well to investigate the actual effect of water quenching after drawing for each type of steel. It is definitely known that chromium-nickel and chromium-vanadium steels, when quenched in water after drawing, show a much higher resistance to shock than when cooled slowly. In the case of straight carbon and straight nickel steels, on the other hand, the resistance to shock does not seem to be affected by the method of cooling after tempering.

Other terms often used in heat treating work are: Cementation, or case hardening; heating a steel above its normalizing temperature in a medium which will increase its carbon content; core of a case hardened bar is the interior portion of the bar which is unaffected in composition by the carbonizing process; bluing—reheating a steel to a specified temperature and allowing it to cool in air.

In the selection of steels to be used in different parts of machines, careful attention should be paid to the manner in which the part in question operates. First, the amount of stress which the piece is expected to stand should be calculated, then the factor of safety should be applied. Then the weight and size of the piece should be determined, also it should be noted whether it will be subjected to wearing, and whether it must withstand shocks or alternating stresses. After these points have been determined, the steel may be selected according to the following general specifications:

Stresses	Metal to Be Used	Composition
Parts subjected to but slight or practically to no stresses or wear.	Medium carbon steel (when aluminium alloys are not permissible).	C, 0.30 to 0.40% Mn, not over 0.75% P, not over 0.05% S, not over 0.05%
Severe wear, but not severe fatigue stresses.	Low carbon steel suitable for case hardening.	C, not over 0.20% Mn, not over 0.50% P, not over 0.05% S, not over 0.05%
Severe wear and severe fatigue stresses.	Low carbon nickel-chromium steel suitable for case hardening.	C, not over 0.20% Mn, not over 0.50% P, not over 0.05% S, not over 0.05% Ni, not less than..... 2.00% Cr, not less than . 0.50%
Severe fatigue stresses, but not severe wear.	Medium hard nickel-chromium steel.	C, 0.30 to 0.40% Mn, not over 0.75% P, not over 0.05% S, not over 0.05% Ni, 2.50 to 3.50% Cr, 0.50 to 1.00%
Severe fatigue stresses or wear or both, when smaller ductility is permissible.	Self-hardening nickel-chromium steel.	C, 0.30 to 0.50% Mn, not over 0.75% P, not over 0.05% S, not over 0.05% Ni, 3.00 to 4.50% Cr, 0.50 to 2.00%
Distortion and softening at high temperature valves.	Tungsten high speed steel.	C, 0.40 to 0.70% Mn, 0.20 to 0.40% W, 12 to 18% Cr, 2 to 4% Va, 0 to 1%

In order to heat treat material, it is absolutely essential to have accurate chemical analysis of the material to start with. It is possible to equip a chemical laboratory for the analysis of all types of alloy steels for about $1500. This includes electrical combustion furnaces for the determination of carbon, but it does not contain any equipment for determining elements by electrolysis.

If the chemical analysis is carefully made, the carbon determination should be accurate to within two points of either side of the true amount. The accuracy in determining all other elements should be in the same ratio. Quite often failures in heat treatment are blamed on inaccurate chemical analyses. About 75 per cent of these complaints can be explained by investigating the actual treatment given the material; in some few instances, the chemical analysis will be found in error.

The success of any heat treatment depends, to a great extent, upon the type of furnace used. Every furnace should be such that the material being heated will receive a uniform heat at all parts and should be capable of accurate temperature control. Fuel economy should always be a secondary consideration.

Care should be taken to see that the furnace, whatever the type may be, is large enough to hold the work, and large enough so that the temperature is not materially reduced when the cold metal is placed in it. It should be so built that the work will receive an enveloping heat, and not a concentrated heat from the flame. In case the furnace is overfired, the temperature gradient of the furnace should be watched carefully and care taken that the floor is kept up to heat.

Furnaces are generally heated either by oil, gas or electricity. Oil firing is satisfactory for large furnaces where an accurate temperature control is not required and where an oxidizing atmosphere is not detrimental. Gas-fired furnaces are capable of more delicate control, both regarding temperature and the oxidizing nature of the burning gases. In case either of the above fuels are used, care should be taken to see that there is proper space in the furnace appropriated for a combustion chamber, and that the hot gases do not strike one part of the material more than another. Electric furnaces are capable of very accurate control. In cases where delicate heat treatment is being done, and where the rejection of a furnace-load of material would be costly, it pays to install this type of apparatus.

Judging a Furnace

In judging any furnace, the following things should be borne in mind:

1. Uniformity of heat.
2. Rate of heating.
3. Method of loading and unloading.
4. Quenching arrangements.
5. Initial cost.
6. Upkeep and repair.
7. Thermal efficiency.

In cases where large quantities of material are to be heat treated, it is well to consider a continuous furnace for the work, but care should be taken that it is long enough to insure uniform heating. If large material is to be rolled through the furnace, the underfired furnace will be found well adapted to the work. In case the material is conveyed through the furnace on trays, the overfired muffle furnace will be found satisfactory. Conditions cannot be controlled very accurately in continuous furnaces.

For heat treating small miscellaneous parts, the ordinary underfired tool-room furnace of sufficient size has been found very satisfactory. In all cases, the material should be piled loosely, allowing a good circulation of gases, and the furnace should not be overloaded.

Speed of Heating

In general, it is permissible to bring the steel up to temperature quite rapidly. In the case of large forgings, however, it is necessary to heat them more slowly. If the outside of such forgings heats too rapidly, it will expand and cause severe tensile stresses in the material. It is thought by some metallurgists that rapid heating has developed "flakes" in nickel steel gun forgings.

The time required to bring any piece of steel up to the desired temperature and the actual temperature desired are questions which have to be settled for each individual case. In general, when hardening, the metal should be quenched as soon as it has reached the desired temperature and has soaked long enough so that the temperature is uniform throughout. In the case of drawing, the material should be held at the desired maximum temperature as long as practical. In cases where very accurate work is desired on small parts, lead baths or salt baths are used for heating the material. Where trouble is experienced with the lead sticking to the material, this can be avoided by first dipping the steel in a solution of potassium cyanide.

Quenching Practice

Quenching tanks should be placed close to the hardening furnaces and arrangements should be made to transfer the hot metal into the liquid as rapidly as possible. Tanks should be covered with a steel lid when not in use.

Every tank should be provided with equipment to circulate and cool the quenching medium. It is better to have a small quenching tank with a high rate of circulation than a larger tank with a slower rate. The oil may be cooled by passing it through a refrigerating machine, by piping it through cold running water, or by cooling with air. In cases where a great many small parts are quenched in a tank at once, provision should be made to have the oil circulate freely among the different parts, or uniform results will naturally not be obtained.

Quenching Media

The most common quenching media are oil, water and brine. Hot lead has been used in some instances, also soap solutions and mixtures of oil and water. Brine gives the harshest quench of all, water next, then the various grades of oil. There is, however, quite a wide gap between the results obtained from water and oil.

Quenching should be considered as a rapid removal of heat from the material down to a temperature of about 500 deg. The rate of cooling steel through the critical range determines the hardness of the material in practice. This rate of cooling has a marked effect on the final physical properties of the steel after it is drawn. Thus, in general, the harsher the quench, the higher the elastic limit will be, in comparison with the tensile strength, but the ductility does not seem to be materially affected.

If water or brine is used as a quenching medium, its temperature should be above 100 deg. F. In case of large forgings, this temperature may be from 100 to 110 deg., while for smaller forgings, it should be increased to 150 or 200 deg.

In using water or brine, there is great danger of developing quenching cracks or of warping the material. For this reason the steel should be immersed in the quenching medium in line with its longitudinal axis, and should be removed when it has reached a temperature of about 500 deg. F. since most of the cracks and warping occur as the steel is quickly cooled below this temperature. There is also danger of developing steam pockets; the steam acts as a heat insulator and causes soft spots in the steel. Only forgings which are symmetrical and of considerable size should be quenched in water.

In general, it is better and safer to quench in oil, providing this medium will give a harsh quench enough

to produce the desired properties. A good quenching oil should not deteriorate upon use, and is judged according to the following physical properties:

1. Specific heat.
2. Heat conductivity.
3. Specific gravity.
4. Viscosity.
5. Flash point.

The temperature of the quenching oil should be over 100 deg. The actual temperature of the medium seems to have little effect on the physical properties of the hardened steel; still it is much more economical to maintain the oil at about 150 deg. and it pays to install sufficient cooling area to keep the oil at this temperature. One gal. of high-grade quenching oil, when used under economical conditions, should quench about 1500 lb. of steel—this figure is contingent on the size and nature of the pieces. Steel taken from oil should be placed on tables, so that the oil will drain back into the tank.

Pyrometric Control

In order to heat treat material intelligently and to obtain uniform results, it is necessary to have all the furnaces adequately equipped with pyrometers.

Base metal thermocouples are commonly made of iron and constantin wire, or chromel and alumel wire. The iron-constantin couple seems to be somewhat more accurate, but it does not seem to have as long a life as the chromel-alumel couple. The platinum-platinum rhodium couple is the most accurate, but the cost of the rare metals makes them prohibitive for commercial use, except for controls.

Electrical meters usually record the potential difference between the hot end of the thermocouple and its cold junction. It is absolutely essential to have the cold junctions of any pyrometric system located in such a place that its temperature will remain practically constant. This can be accomplished most readily by burying them in the ground at a distance of 4 or 5 ft. from the furnace. However, other arrangements which provide a constant temperature are satisfactory.

There are two general types of meters. One is a low-resistance instrument (milliammeter or galvanometer) and the other a high-resistance instrument (millivoltmeter). The low-resistance instrument is more robust than the other, but it is effected to a greater extent by variations in the resistance of the leads, poor connections, etc.

For more accurate work a potentiometer with an iron-constantin couple seems to give good results. This instrument can also be used with couples made of any other combination of metals, since in this system, an electromotive force is introduced into the circuit which just counteracts the electromotive force generated in the thermocouple. When the indicator on the potentiometer shows that no current is flowing, the amount of electromotive force introduced is read and transferred into degrees by the use of a calibration chart. This type of installation is not affected by the resistance of the leads or by oxidation of the thermocouple. It registers accurately as long as part of the weld in the thermocouple holds together.

Any pyrometric system is only as accurate as the calibrating and checking equipment available. Thermocouples should be checked at least once a week, preferably by placing a standard base metal couple beside thermocouples that are being used in furnaces and reading temperatures registered by the two. The standard base metal couple should also be periodically checked in an electric furnace against a standard rare metal couple, or it may also be checked by melting points. In this case, care should be taken that the melts are pure and that it is used in a graphite or ceramic container. Iron tubes should not be used in the salt bath. A vertical electric furnace about 3 ft. long and 3 in. in diameter will be found well adapted to such work.

Placing the thermocouple in the furnace is very important. Care should be taken that the temperature at the end of the thermocouple is the same as that of the material being heat treated. (This can be checked in hardening furnaces by use of an optical pyrometer—the Leeds Northrup pyrometer is very satisfactory for this work.) If the pyrometer reads 1550 deg., it is no proof that the material is at this temperature, but if thermocouples are properly installed and checked, one should be able to control the temperature of the material to within 10 deg. on either side of that desired. In general, however, the temperature is rarely controlled within a range of 20 deg. plus or minus.

Physical Tests

After the material has been heat treated, it should be subjected to some sort of a physical test, the tensile test being universally used. When the test bar is pulled, the elastic limit, tensile strength, per cent elongation and per cent reduction of area should be calculated and recorded, together with the nature of the fracture.

The elastic limit may be determined in several different ways, the most accurate method being the "increment" method. This consists in clamping an extensometer on the test bar and noting the stretch as each 1000 lb. per sq.in. load is added to the bar. The point at which the stretch ceases to be proportional to the added load is taken as the elastic limit to the specimen.

Other methods for getting the elastic limit are the "run extensometer" method, "scribe" method, "modified scribe" method and "drop of the beam." In the "modified scribe" method, the test specimen is first scribed with dividers set at a length equal to the gage length of the test specimen, one end of the divider being set in a punch mark on the specimen. A load corresponding to the minimum elastic limit required for the material is then applied, care being taken that the beam balances under this load. The load is then released and the test specimen is scribed again. If after this second scribing two distinct lines are seen, the elastic limit is considered as having been exceeded, while in case there is no permanent set in the specimen, the elastic limit has not yet been reached.

Per cent elongation and per cent reduction of area are an indication of ductility. Per cent elongation is contingent upon the relation between the original area of the specimen and the gage length, and the following general relation should exist:

$y^2 = 20x$, where y is the gage length and x is the area of the test piece.

Number of Tensile Tests

The number of tensile tests that should be taken from any lot depends entirely on the importance of the properties measured by this test as related to the stresses set up in the piece when in operation.

Compression tests are often made on steel and cast iron in order to obtain information as to the amount of direct loading the material will stand and also as a

measure of the ductility of the material. A compression test specimen is usually a cylinder, whose diameter is equal to its height. The specimen is then compressed to one-half of its original height if it does not break before that point. The elastic limit in compression can be determined the same as in tension.

Bending tests are often made to determine the ductility of steel. This test generally consists of bending the piece flat about a rod whose diameter is equal to the thickness of the piece.

Torsion tests are also made in a twisting machine which measures the amount of force required to twist the steel to a certain angle. This test is applied to steel which is to be used for axles, crank shafts or similar work.

Fatigue tests are often made on steel to determine the amount of alternating stresses the material will stand before breaking. This test generally consists of rapidly bending a piece of steel back and forth without exceeding the elastic limit, and measuring the number of such bends required to break the material.

Shearing Tests

Shearing tests are often made on steel which is required to stand up under shearing stresses. In this test, a specimen is broken in a machine which measures the force required to shear a standard specimen in two. This force is then divided by cross-section area.

Impact tests should be made on all material which will be subjected to shocks. The most common types of impact machines are the Izod and the Charpy. Both have a heavy pendulum, which swings from a certain height and breaks the specimen, the amount of energy remaining in the pendulum being measured by the distance which it swings after striking the specimen. It is very important to have the specimens accurately machined for this test, and if it is notched, it should be done on a special milling machine which is used only for this one purpose.

Drop Tests

A drop test is often used on cast iron and steel. This consists of dropping a weight from a specified height repeatedly until the material breaks, or by starting at a specified height and increasing the drop by a certain increment each time until failure. The test bar is supported on knife edges, the radii of which have a very important influence on the results.

It is impossible to estimate the impact resistance of a piece of steel by any other test; that is, steel which has the same chemical analysis when heat treated in different ways may give exactly the same tensile properties, but have entirely different resistance to shock. This is particularly true of steels containing chromium and vanadium.

The hardness of steel is measured in several different ways. The Brinell test consists in applying a weight of 3000 kg. through a 10 mm. steel ball upon the material for 30 sec. The diameter of the impression is then read by a microscope, and the hardness number taken out of a table. This test is fairly indicative of the tensile strength of the material. From the Brinell number, knowing the chemical analysis of the steel, one should be able to estimate the tensile strength to within 5000 lb. per sq.in. It is also an excellent test to check the uniformity of heat treatment. In testing a lot of material, it is well to Brinell a portion of them and then select the softest one for tensile tests. In this way it is certain that the softest piece in the lot meets the physical requirements.

Hardness may also be tested by the Shore scleroscope. In this test a tiny pointed hammer is dropped on the material from a certain height and the height of rebound is measured. The surface tested should be carefully smoothed and the small hammer should not drop twice in the same place. The piece being tested should also be supported solidly. The results of this test cannot be interpreted to read elastic limit, tensile strength or Brinell hardness with any degree of accuracy; however, there is a very general relationship between these properties.

Special tests are often made on small heat treated parts on specially designed machines, which aim to set up stresses in the piece similar to the ones it will be required to resist in operation. These tests are either run until the piece breaks, or until it has withstood the tests for a specified time. Such tests are very satisfactory and should be applied wherever possible.

Micrography

Microscopic examination of steel is of great assistance to a metallurgist, and at times indispensable. For tracing causes of failures and for laying out heat treatment for new parts, such examination can be used to great advantage.

A cubical specimen about $\frac{3}{4}$ in. on a side is about the best size to handle in polishing. One surface should be ground or filed flat. It should then be polished on a regular polishing wheel until all scratches are taken out. It is well to examine a surface under a microscope before etching. The specimen can then be etched in a 5 per cent solution of nitric acid and alcohol, or a 10 per cent solution picric acid in alcohol.

Any examination of steel is really incomplete without the microscope. It is an excellent check on all other tests and analyses. Before making any definite statements concerning the structure of the steel, the chemical analysis should be known, together with the heat treatment the material has received.

Conclusion

As stated in the first part of this paper, heat treatment work is entirely quality work. In order to accomplish this, it is necessary that every man working in the heat treatment department be intensely interested in his work. In order to maintain the interest of the men, it is necessary that every man should be educated as much as possible in the line of work he is handling and should view his work at all times with an inquiring attitude. Each man should be encouraged to think about the work he is handling and should be allowed to exercise the creative side of his nature whenever possible. Responsibility should also be placed upon the men who are actually performing the operation; this can be accomplish by allowing the men to visualize their work by the use of graphs and charts. Interest can be maintained by keeping progress reports of the men throughout definite periods. These records should be open to the men at all times; they should be kept only with the idea of showing the men to what extent they have mastered the work they are handling, and to see the comparison between what they and the other men are doing. When the heat treatment department is organized on these principles, the maximum production will be obtained with the best quality.

Cost information, similar to the following, should be available to the metallurgist:

1. Direct labor cost.
2. Indirect labor.
3. Overhead.
4. Price of materials used.
5. Quantity of material heat treated.
6. Quality of material heat treated.
7. Quantity of material quenched per gallon of quenching oil used.
8. Cost per unit weight of material heat treated.

These figures should be carried forward on chart record.

Rochester, N. Y.

Determination of Uranium, Zirconium, Chromium, Vanadium and Aluminium in Steel—I

By Charles Morris Johnson

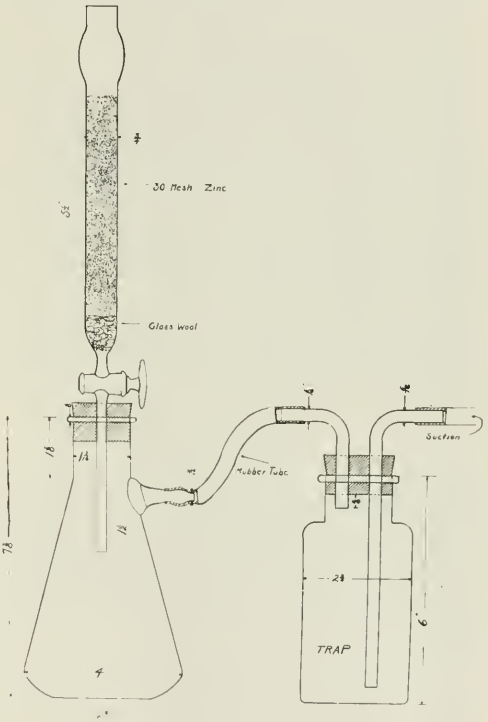
THE feature of the following method is to remove the bulk of the iron from the uranium, zirconium and aluminium before making determinations of these elements by fractional precipitation by ammonia. The analysis can then be proceeded with in a simple and accurate way. The separation of the bulk of the iron is based on the fact that when ammonia is added to iron in the ferrous state the unoxidized iron is first converted to double sulphate of ferrous iron and ammonium and remains in solution. By adding the ammonia very slowly with constant stirring a point in the neutralization is reached where a slight reddish precipitate forms. On the addition of a few drops more of ammonia this reddish precipitate darkens. At this stage all the aluminium, zirconium, uranium, etc., are precipitated, while 99 per cent of the total iron remains in solution as double sulphate and is removed by filtration. By actual test with 10 g. of plain steel to which uranium salt was added, over 99 per cent of the iron was removed.

Uranium in Plain Steel

Dissolve on a low flame 5 g. of drillings in 50 cc. 1:3 sulphuric acid diluted with 50 cc. of water, using a 600 cc. beaker. For steel containing less than 0.1 per cent uranium use 10 g. of sample. When action is over, filter off the insoluble residue, which is mainly carbide, and wash it 25 times with dilute sulphuric wash (25 cc. of 1:3 H_2SO_4 diluted with water to 600 cc.). Call this filtrate and washings *A*. The insoluble residue may contain U, so it must be ashed in a platinum crucible at a low heat; cooled; 6 cc. of HF plus 6 cc. of 1:3 sulphuric acid added; evaporated to thick fumes of SO_3; cooled; a little water added; heated to dissolve the sulphates and the clear solution is added to *A*. Then dilute to 250 cc. volume with water and add 1:1 ammonia with constant stirring until a slight precipitate forms. Then continue to add ammonia drop by drop until the precipitate just begins to take on a blackish tint. At this stage all the uranium has been precipitated with only a small portion of the iron.

To assure a complete precipitation of the uranium, add about 10 more drops, but do not exceed 10 drops, as excess ammonia only brings down a greater bulk of the iron. Filter off the precipitate at once on a double 15 cc. filter paper and redissolve it in 50 cc. 1:1 HCl. First warm up the acid in the beaker to dissolve any iron that sticks to the sides; then pour the hot acid on the precipitate, catching the filtrate in a 600 cc. beaker. Pour hot filtrate on the filter two or three times until all the iron is in solution. Wash the filter paper about 25 times with dilute HCl wash (1:40). Now peroxidize the filtrate and washings by adding, slowly, with a porcelain spoon, about 1 g. of sodium peroxide at a time. After each addition wash off the sides of the beaker with water and stir the solution well. Keep on peroxidizing until all the iron is precipitated and the solution is alkaline when tested with red litmus paper.

Now add about 5 g. of sodium carbonate and 5 g. of ammonium carbonate to keep the uranium in solution.



REDUCTOR FOR U AND FE

Stir well and bring it just to a boil. Filter off the iron and wash it about 25 times with sodium and ammonium carbonate wash (2 g. of Na_2CO_3 and 2 g. of $(NH_4)_2CO_3$ dissolved in 600 cc. of water). To the filtrate which contains all the uranium add 1:1 HCl with stirring, till solution no longer turns turmeric paper even a faint brown, but still reacts alkaline when tested with red litmus paper. Keep the beaker covered when adding the acid, as the effervescence is very strong, especially toward the end of the neutralization. Boil off the CO_2 and then add slowly with stirring (keeping the beaker covered) 1:1 HCl till the solution is slightly acid. No more effervescence at this stage, but the acid falls down to the bottom of the beaker without action.

Boil the acid solution for half an hour to remove CO_2 and after it has been cooled add 5 g. of ammonium phosphate $(NH_4)_2HPO_4$; stir till dissolved; then add 1:1 ammonia till it smells ammoniacal and add 1:1

acetic acid till the solution is acid; now add 5 cc. acetic acid in excess. The acetic acid keeps any chromium and vanadium present in solution. Chromium does not interfere with the uranium titration, but vanadium interferes greatly.

After a few hours, filter off the uranium and wash it about 40 times with acetic wash (5 cc. of ammonium phosphate, 10 cc. 1:3 H_2SO_4 diluted with 100 cc. of water, stir till dissolved, make it slightly ammoniacal and then acid with acetic acid 5 cc. in excess. Dilute with water to 600 cc.). Redissolve the uranium in 50 cc. hot 1:3 H_2SO_4 by pouring the hot acid back and forth two or three times on the precipitate, catching the filtrate in a 400 cc. beaker.

Wash the filter paper about 30 times with dilute H_2SO_4 water. In high vanadium steel it is better to test for vanadium by adding 5 cc. of H_2O_2 to the solution and noticing whether it changes to brown; if it does, make another ammonium phosphate precipitation to remove the vanadium. If the solution does not change in color, bring it to a boil; then add several drops of $KMnO_4$ till it gets a pink color that will not fade after 15 min. boiling. Cool the oxidized solution to room temperature. Now reduce the uranium by passing it slowly through a zinc reductor and immediately titrate the reduced solution with a standard $KMnO_4$ solution to the first appearance of pink that spreads all through the solution. If there is any vanadium in the solution at this stage the pink will disappear in about 5 sec. instead of holding one minute. Any more permanganate added that disappears after 5 sec. standing is due to vanadium that has been carried over as phosphate.

Jones Reductor

The column of zinc in the reductor rests on a $\frac{3}{4}$-in. plug of glass wool. The zinc column is $5\frac{1}{2}$ in. long by $\frac{3}{4}$ in. in diameter consisting of 30 mesh grains of amalgamated zinc. The amalgamation is accomplished by stirring the 30 mesh zinc under a covering of mercuric chloride solution made by dissolving 50 g. of $HgCl_2$ in 1000 cc. of water. The zinc after amalgamation is washed with distilled water by decantation in a beaker until free of excess mercuric chloride, when it is ready for use.

A trap jar is placed between the filtering flask and the suction to prevent back pressure which would carry water over from the suction pump into the flask which holds the filtered, reduced, solution of uranium. The volume of the uranium solution to be reduced is about 50 cc. This is passed through reductor slowly, i.e., at the rate of 50 cc. per 10 minutes.

After passing the solution through the reductor, wash the zinc with dilute H_2SO_4 (1:6) three times, 10 cc. each time, and then three times more with 10 cc. of water each time; drawing off each washing completely before adding next washing. The volume before titrating is about 100 to 110 cc.

For convenient calculation 2.29 g. $KMnO_4$ are dissolved in distilled water and diluted to four liters.

1 cc. $KMnO_4$ Standard = 0.002169 gram U.

1 cc. $KMnO_4$ Standard = 0.001014 gram Fe.

The standard $KMnO_4$ can be checked for its uranium and iron value by titrating it against sodium oxalate.

Uranium in Chrome Tungsten Steel

Dissolve 5 g. of steel in 50 cc. of 1:3 H_2SO_4 diluted with 50 cc. of water; after action is over, filter off the insoluble residue and dilute the filtrate to about 250 cc. volume with water. Now add 1:1 ammonium with constant stirring until the precipitate at first takes a reddish tint, next changing to a blackish and finally to a bluish-whitish. At this stage add about 2 cc. of ammonia with stirring to complete the precipitation of all the uranium in the filtrate with only a small portion of the iron. Filter it off at once and finish as in plain uranium steel.

The insoluble tungsten and chromium carbide residue on the filter was found to contain some of the uranium. Wash it off the filter paper with dilute sulphuric acid into the original beaker, heat it, and then oxidize it with 30 cc. of 1.20 nitric acid. Keep on heating on a low flame until the residue is bright yellow. Filter off the tungsten, wash it about 25 times with dilute H_2SO_4 wash; and peroxidize the filtrate with sodium peroxide to separate the uranium from the iron. Catch the uranium filtrate from the main peroxidation and that from peroxidation of the insoluble residue in the same 800 cc. beaker and finish as in plain steel.

A variety of mixtures was tested by adding different portions of uranium acetate (56.13 per cent). The results are given below.

TABLE SHOWING URANIUM ADDED AND FOUND TO 10 GRAM SAMPLE OF PLAIN STEEL

Added Gram Uranium	Found Gram Uranium
0.0112	0.0119
0.0143	0.0143
0.0168	0.0169
0.0280	0.0286
0.0561	0.0573
0.0056	0.0055
0.0084	0.0085

Ten grams of plain carbon steel—no uranium added.
$KMnO_4$ 1.2 cc. reading of burette after titration.
$KMnO_4$ 0.0 cc. reading of burette before titration.

$KMnO_4$ 1.2 cc. = blank which is deducted.

Uranium, chromium and iron mixture; chromium added as $K_2Cr_2O_7$ to 10 gram sample of plain steel before dissolving same in H_2SO_4.

TABLE SHOWING URANIUM ADDED AND FOUND TO 10 GRAM SAMPLE OF STEEL

Added Gram	Found Gram
0.0056	0.0057
0.0084	0.0085
0.0280	0.0286
0.0561	0.0558

TABLE SHOWING URANIUM ADDED AND FOUND TO 5 GRAM SAMPLE OF TUNGSTEN, CHROME, VANADIUM STEEL

Added Gram	Found Gram
0.0112	0.0113
0.0280	0.0278
0.0561	0.0575

Five grams—no uranium added.
1.8 cc. reading of burette after titration.
0.0 cc. reading of burette before titration.

1.8 cc. = blank which is deducted.

About 80 per cent of the iron is removed by ammonia precipitation in the filtrate when large amounts of carbides of tungsten, chrome and vanadium are present, as was found by actual test. The bulk of the 20 per cent of iron that remains to be separated by peroxidation is found in the carbide residues of these steels.

Crucible Steel Co. of America.
Pittsburgh, Pa.

Continuous Distillation of Tar

According to *Commerce Reports*, May 6, the Hird process for the continuous distillation of tar is being used successfully in England, Japan and Australia, 130 plants having been erected at a cost of about $1,500,000. In England, this process is rapidly superseding all processes hitherto used.

Sintering Zinc Residues

A Description of One of the Methods Used by the Bartlesville Zinc Co. to Recover Values From Zinc Retort Residues—Most Excellent Blast-Furnace Material Containing Values in Gold, Silver and Lead Is Made From Oxidized Fines With No Fuel Additions

By K. STOCK

ZINC ores and concentrates from the Rocky Mountain region containing various amounts of lead, copper, gold and silver are treated at the zinc smelters of the American Metal Co., located at Bartlesville, Okla. After roasting and retorting in the usual way, all residues, now containing not more than about 6 per cent of their original zinc contents, are subjected to an additional treatment depending upon the amount and nature of other metals to be recovered. For instance, a residue low in gold and silver, when admixed with complex zinc-lead ores, is burned on a Wetherill grate to a discarded clinker and a valuable fume of lead sulphate and zinc oxide. Retort residues ("ashes," so called) higher in gold and silver are clinkered in heaps, after the Petraeus patents, producing a most excellent, porous blast-furnace material (Fig. 1) with no other fuel than the excess carbon remaining from the distillation.

Metal Losses

Residues are selected so that the resulting sinter shall have a lead content as much above 5 per cent as possible (even after a moderate volatilization loss during the operation), 5 per cent being the minimum limit for payment according to smelter schedules. Zinc burns off to a rather larger extent than does lead, but even so the clinker may run above 10 per cent at times and be assessed a corresponding penalty. Copper, gold and silver show virtually no losses unless large blowholes in the burning pile are left untended, when the silver values especially will show an unusual deficit. To be specific, a typical residue charged on a heap may be a mixture of Butte and Cœur d'Alene residues of the following compositions:

	Butte Residue Per Cent	Cœur d'Alene Residue Per Cent
Zn	10.2	7.5
Fe	7.2	11.0
Mn	0.7	0.4
Pb	4.7	9.0
Insoluble	30.0	27.5
Cu	0.6	0.2
Carbon	35.0	30.0
Ag	37 oz.	6 oz.

Typical Clinker Analysis

Such residues are mixed on a pile "as they come." Straight Butte residue is too low in lead for payment, while straight Cœur d'Alene residue has so much lead that it softens and does not sinter well. A typical clinker analyzes as follows:

	Per Cent		Per Cent
Zn	12.0	SiO_2	38.0
Fe	12.9	Cu	0.8
Mn	1.1	C	1.2
Pb	9.8	Ag	27 oz.

Naturally the clinker will vary considerably from these figures, depending upon the relative proportion of the main constituents which find their way into the bed.

Metallurgical balance sheets for a couple of years show the following losses:

	Per Cent		Per Cent
Shrinkage in weight	32.0	Pb	— 8.9
Au	— 2.8	Zn	—18.1
Ag	— 3.2	Fe	— 2.8
Cu	+ 1.4	Mn	— 7.2

Of these losses, those in silver, lead and zinc represent principally volatilization losses, while those of other metals are largely due to dusting and windage. Gain in copper is probably due to analytical errors (our residues ordinarily are quite low in this metal), while the figures for gold, iron and manganese are probably subjected to the same error, at least to as great an extent. Volatilization of a large percentage of zinc is naturally desirable, since we are making lead blast-furnace material, but an accompanying loss in lead and silver counteracts the gain.

During the operation the weight is diminished almost entirely by the elimination of carbon, so that 100 lb. of fine, bulky "ashes" will produce 68 lb. of scoria, as noted above.

Building the Kiln

The clinkering beds or "kilns" are each 47 to 50 ft. square at the bottom, and are ranged in a long row, skirted on one side by an air main and on the other by tracks for locomotive crane and railroad cars (Fig. 2). The site is prepared by carefully leveling the earth and building a series of air channels of loose brick, covering the area like a gridiron, as is sketched in Fig. 3, and shown in the foreground of Fig. 2. At the rear center of the pile a long-radius bend of 12-in. riveted pipe leads from the air main to a breeching built of brick or tile bats, cemented and covered with a fairly large mound of earth to prevent air-leakage or damage from clinker removal. This breeching divides the air

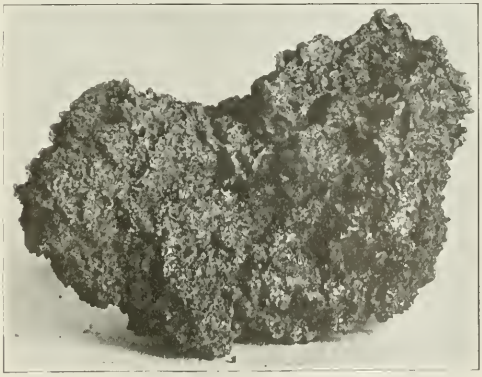


FIG. 1. TEXTURE OF CLINKER

FIG. 2. LOOKING DOWN A ROW OF CLINKERING BEDS

current into a header leading to right and left along the back of the pile and parallel to the air main, which header is constructed as follows: The central third is composed of two walls of closely dry-laid brick, four courses high and 4 in. apart, while the end portions are built but three courses high. The roof merely consists of square brick or tile closely laid to exclude infiltering fines. At intervals of 3½ ft. a half-brick is removed from the front wall, from which openings the minor channels lead clear across the pile toward the front. These channels, 13 in number, are somewhat similar to the headers; they are built of dry brickwork, the bottom courses consisting of half-bricks, however, while the top courses and roof are tight. This provides a great many relatively large openings through which the air blast may find its way out into the pile above. All these channels are then covered with a thin ridge of earth, patted down with a flat shovel, and the area is ready for ashes.

Two men are required to perform the work of smoothing down the ground, building and covering the air channels.

Retort residues are brought to the heaps either in the tram-cars which operate in the furnace cellars, or in standard gondolas. For the former, an elevated track traverses the site of several piles (Fig. 2); this track will probably be dismantled in favor of the practice to be immediately described, thus eliminating the work of two trammers. Railway cars, filled with residue ashes through traps, are switched to the site of a new pile, and approximately 100 tons are unloaded by locomotive crane and clam-shell bucket in a ridge at the rear of the pile, as shown in Fig. 4, covering the back header with the toe of the slope occupying the position a few feet beyond the channels sketched in Fig. 3. Two more carloads are piled along the front of the heap, thus leaving a trough across the area midway from front to back, where for a short distance all of the 13 parallel channels are yet uncovered.

When two more carloads of residue are spotted ready for this heap, an armful of coarse wood is deposited in the short valleys remaining exposed between air channels, a shovelful of hot coals placed on the wood, and the whole covered with residue from the adjoining slope. When a row of fires is kindled in this manner across the pile, a little air is admitted by raising the slide gate somewhat, and the locomotive crane proceeds to unload the two cars into the trough, finishing out a square pile which when trimmed off becomes about 5 ft. deep (Fig. 5). By this time the air gate is wide open, and the blast, working its way through the earth channel-coverings, fans the coals and kindlings into life; thence the combustion expands through the mass in all directions.

Within a few hours smoke begins to emerge from an area across the center of the pile, gradually widening as the fire works its way from the points of kindling. Within a week it has extended to the entire area of the pile, and the center, burning since the first, has sunken somewhat. This depression is kept level, however, by adding more ashes, in order that the resistance to escaping blast may be approximately the same in all parts. All burning piles are inspected several times each 24 hours, and any blowholes which may appear are smothered under a small heap of fresh residue. As combustion proceeds and the pile settles, a new carload of ashes is spread over the surface, this practice continuing until four to six extra carloads of residue have been added, making a total of 500 to 600 tons residue in one heap. Despite tight construction of the header, the rear portion of the pile burns more rapidly than the front, and consequently the unburned additions are spread much more liberally on this region, and the clinkered mass is deeper in consequence.

After about a month the pile has been built to its maximum depth and pretty thoroughly burned. Fire constantly breaks through at so many different places that one man spends the largest part of his time digging out the black sandy residue from unburned spots and heaping it over the tiny volcano craters. During this last stage, the surface of the pile becomes naturally very irregular (Fig. 6)—mounds cover these places where for some reason or other the blast was most effective,

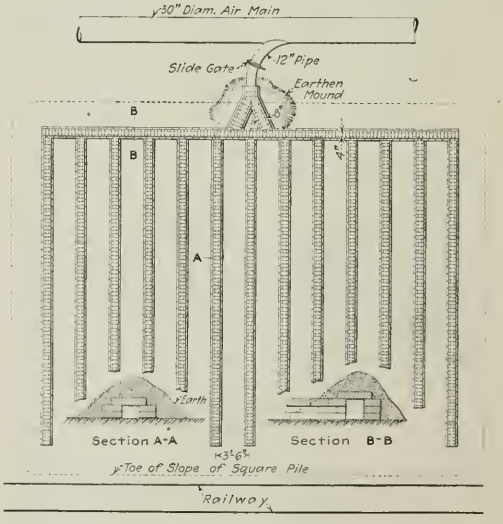

FIG. 3. PLAN OF CLINKERING HEAPS

FIG. 4. AIR CHANNELS COMPLETED AND FIRST CARLOAD OF RESIDUE UNLOADED

while other portions of the pile where little air penetrated are almost denuded of material. As the unburned cover becomes thinner the air supply is gradually reduced, and at the end of the operation the surface of the pile is a brownish granular mass, covering the sintered material to a depth of a couple of inches. This covering, although having lost the large part of its carbonaceous material, radiated its generated heat so rapidly that fusion was impossible.

For all work in trimming up the piles, five day men and one night man are employed. While actually on a burning pile, the workmen move about on short pieces of plank, so that their weight may not break through into an incandescent cavity, which sometimes exists several feet in diameter.

Loading Clinker

Burning a pile thus requires in the neighborhood of 35 days. When this stage is finished, the air is completely shut off, and a garden hose set so as to sprinkle water over the surface, wetting continuously for three days before the pile is cool enough to handle. Speedy cooling is of advantage further than as a time saver, since slowly cooled clinker is very tough, while quenched clinker breaks more easily. The pile now consists of a large thick clinker, more or less continuous, covered by a thin blanket of unconsolidated fines, but in all much too solid for removal by hand or machinery. Consequently the pile is broken up with powder.

A 2-in. bar is driven down to the ground level at intervals of about 5 ft. between each pair of air channels. On removal of the bar the hole is inspected, and if there is reason to suspect that the material at the bottom is not quite cold, water is hosed into it for some time. A line of cold holes is then loaded with a stick of dynamite in each, some fine material sifted in for tamping, and the charge fired with slow-burning fuse. The powder charge is naturally varied according to conditions—the idea being to lift the mass but slightly, cracking it into one-man size, without throwing even the fines more than a few feet. A crew of seven men then attack the broken pile with sledge, pick and shovel, moving the sinter a few feet to the rear on clean ground, separating out the earth covering from the air channels and reclaiming the brick.

FIG. 5. COMPLETED HEAP

A locomotive crane then loads this piled clinker by means of a clam-shell bucket and the area is ready for rebuilding the air channels. Unsuccessful trials demonstrated that this style of bucket, even when equipped with teeth, was totally unable to dig the pile after it had been broken up with powder. While an orange-peel bucket would doubtless handle such material, considerable time would be required to make the frequent changes in buckets, since this style is unsuitable for unloading cars, which, in fact, is the most essential part of the cranes' duties. Even so, digging by machine must stop at a level a few inches above the tops of the air channels in order to avoid loading a large tonnage of earth cover and bats, leaving the balance of the clean-up to be done by hand labor. Working on such a scheme the loss of time and inconvenience of changing buckets would tend to offset the hand digging saved.

FIG. 6. IRREGULAR SURFACE OF BURNED HEAP

A layout which would allow complete clean-up by clam-shell bucket would require a solid floor traversed by depressed air conduits and covered by a layer of refractory ore. Such a floor must resist the extremely high temperature generated during the sintering operation, and still be tough enough to resist the impact of a heavy bucket. A cyclopean sheet cast in large blocks each containing several tons of slowly cooled slag would most likely answer the requirements, but large quantities of molten slag are not obtainable at most zinc smelters. Slag brick, on the other hand, are notoriously unsatisfactory. Extra large vitrified paving block, well cemented, might serve, but would make a very expensive foundation. Any such scheme would further involve a plant cost which is entirely lacking and is the most attractive feature of the present installation, and would probably more than absorb the present labor costs in maintenance and capital charges. Should the present crane be crowded with work to a point where it could not load the rehandled clinker without overtime, a portable conveyor loader would be the logical machine to take the lumps direct from the pile into a gondola.

The sintering plant at Bartlesville comprises a long

row of 17 such "kilns," and ships from 40 to 45 carloads of blast-furnace material monthly—approximately 2100 tons. The daily cost of operation is approximately as follows:

Labor:		
Day foreman and engineer	$4.00	
Night engineer	3.50	
Powderman	3.50	
2 Trammers	6.00	
6 Spreaders	18.00	
7 Diggers	21.00	
2 Men on air channels	6.00	
Total labor		$62.00
Crane:		
Engineer	$6.75	
Fireman	3.25	
Helper	3.00	
Upkeep of crane	25.00	
Cost of crane per day	$38.00	
Crane is busy 33 per cent of its time on this work		13.00
Power		6.00
Switching ashes		10.00
Powder, small tools and miscellaneous supplies		6.00
Superintendence and general charges		10.00
Total daily cost		$107.00

This figures to $1.53 per ton of clinker produced, and in any case should be less than the saving in freight on clinker as compared with crude residue between zinc plant and lead smelter, plus the cost of sintering green residue in a mechanical roaster at the latter place. An additional tangible advantage whose monetary value is difficult to assess lies in the fact that the clinker thus produced is a much more desirable blast-furnace charge from the physical standpoint than ordinary calcine, being quite strong and coherent, yet porous, and containing less than 15 per cent fines (Fig. 7).

General Considerations

Many different kinds of residues have been satisfactorily sintered at the Bartlesville plant in this manner. Apparently lead cannot be too low to prevent clinkering, since in any residue yet tried at this plant there is enough iron and lime either in the original ore or in the fuel ash to properly bind the mass together.

FIG. 7. PILE OF CLINKER READY FOR SHIPMENT TO BLAST-FURNACE

Indeed, a residue containing 10 per cent lead or more is very difficult to sinter, since it melts so easily, becoming viscid, compacting together and obstructing the air blast.

It has been found that a large volume of low-pressure blast is much better than a smaller quantity of air at high pressure. The latter gives a glassy non-porous clinker, through which the air breaks into blowholes or intensely heated craters from which high losses in lead and silver occur. The pile is unevenly burned, poorly agglomerated and high in carbon. For blast purposes we use a No. 10 Sturtevant blower, belt-connected to a 50-hp. gas engine, discharging into a long air main tapering from 30 in. to 18 in. at the extreme end. It has also been found that the distance center to center of air channels has an important effect upon the resulting coke—if they are much beyond 4 ft. apart the material at the bottom of the piles is not coherent, while deep troughs often have to be dug in unburned material above these regions toward the end of the burning stage.

Bartlesville Zinc Co.,
Bartlesville, Okla.

Removal of Limitations on Export of Silver

On Aug. 15, 1918, the Federal Reserve Board announced that licenses for the export of silver would thereafter be granted only for civil or military purposes of importance in connection with the prosecution of the war and only in cases where the exporter certified that the silver to be exported had been purchased at a price which did not directly or indirectly exceed $1.01½ per oz. one thousand fine at the point where silver is refined in the case of silver refined in the United States or at the point of importation in the case of imported silver.

The occasion which required the above limitations on the export of silver having now passed, the Federal Reserve Board will hereafter, unless a governmental necessity should again arise, resume its former policy of granting freely and without condition all applications for the export of silver bullion or of silver coin of foreign mintage.

This change of the policy of granting licenses does not do away with the necessity of filing an application for licenses to export silver bullion or silver coin of foreign mintage. Such applications must, as heretofore, be filed through the Federal Reserve Bank of the appropriate district, but such applications will, as stated above, be freely granted by the Federal Reserve Board.

The Secretary of the Treasury does not contemplate any further sales of silver under the Pittman act, except to the Director of the Mint.

Research Fellowships at University of Idaho

In co-operation with the United States Bureau of Mines and the Idaho Bureau of Mines and Geology, the University of Idaho offers in the School of Mines a number of fellowships. These fellowships are open to college graduates who have had good training in mining, metallurgy or chemistry and who are qualified to undertake research work. The income of each fellowship is $720 a year for the twelve months beginning July 1, 1919.

For 1919-20 the following subjects are being considered:

(1) Flotation—with especial reference to differential separation of various minerals.
(2) Availability of Western wood oils for flotation purposes.
(3) Treatment of the complex gold-silver ores of southern Idaho.
(4) Ore dressing problems.
(5) Mining problems.

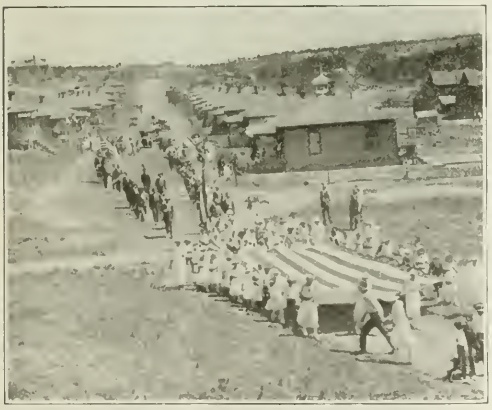
Applications, with certified copy of collegiate record, statement of professional experience, and names and addresses of three references, will be received up to June 1, 1919. The applications should be addressed to the Dean, School of Mines, Moscow, Idaho.

Americanization Work by the Colorado Fuel & Iron Co.

THE TRANSFORMATION of an alien immigrant into a useful American citizen is not completed when he has been taught to speak the English language. Recent events give ample evidence that some of the men who speak English most fluently—and most volubly—in public and in private are about the worst of Americans. On the other hand, ample proof of patriotism has been given time and again by foreign workmen whose knowledge of English is extremely limited. No one should attempt to belittle the importance of instruction in the English language. There is danger, however, that some will consider this instruction the chief end and aim in the Americanization of our alien workmen.

The Colorado Fuel & Iron Co. has about 12,000 employees, of whom the majority are of foreign birth or parentage. In 1916, after a survey of the company's steel works and mining camps by Dr. Peter Roberts, Immigration Secretary of the International Y. M. C. A. Committee, instruction in English was begun for the benefit of those workmen unfamiliar with the language of their adopted country. This instruction has since been carried on principally by the Y. M. C. A. secretaries who are in charge of the clubhouses at the various properties of the company. The instructors have proven energetic and efficient, and good progress has been made by pupils of various ages and different nationalities.

After the entrance of the United States into the war the company and the Y. M. C. A. received the hearty cooperation and assistance of Mr. J. C. Stephens, Director of the Committee on Americanization, Colorado State Council of Defense. Under his guidance it is expected that progress in the teaching of English and in preparing foreign workmen for citizenship will be even more rapid than before. In its endeavors to make good American citizens out of its alien workmen, however, the Colorado Fuel & Iron Co. has laid principal stress upon factors which it believes to be even more fundamental than instruction in English. The Italian, Greek or Slav, transplanted into a mining camp or a steel plant, if left to himself, is tolerably certain to acquire a smattering of English. What is less certain, however, is that he will at the same time learn American principles of government and American standards of living. The proverbial—and generally mythical—miner who stores coal in his bathtub is in need of something more than instruction in the English language. It is necessary that he be taught the principles of our system of government and what it stands for.



PATRIOTIC PARADE OF COLORADO FUEL & IRON CO. MINERS

The Colorado Fuel & Iron Co. is endeavoring to meet the needs of education in American ideas of government and standards of living through a careful fostering of community spirit and through a program of social and industrial betterment. This work is founded upon the Industrial Representation Plan—the so-called Rockefeller Plan—under which all employees deal with the company through representatives elected from among their own number. Through the constant application of industrial democracy, it is believed that sound principles of political democracy will be engendered.

DOMESTIC SCIENCE CLASS IN PUBLIC SCHOOL IN A COLORADO FUEL & IRON CO. CAMP

By means of the activities of the Y. M. C. A. and the social and industrial betterment work carried on by the company, different races and nationalities are brought into social intercourse and fellowship. This has been found beneficial to the workmen and the employer and doubtless tends to increase loyalty to American institutions. High wages, modern housing and the teaching of housekeeping have gone far toward establishing American standards of living. In the public schools in the various communities the children of employees of all nationalities are brought into contact with the English language and American ideals. At one of the schools a number of years ago a plan was inaugurated of giving the children credit for the work they did at home in teaching their parents the English language and subjects relating to American citizenship.

Since the United States entered the war against Germany, patriotism has been taught forcibly and directly to the employees. Encouragement has been given to enlistment in the Army and Navy and to contribution to the various loans and war funds. The result of this encouragement has been exceedingly gratifying and leads officers of the company to believe that the lessons in citizenship taught in the past have borne abundant fruit.

Metallic Coatings for Rust-Proofing Iron and Steel—II

Metallography of Zinc Coating—Variation in Structure of Hot-Dipped, Sherardized, Sprayed and Plated Galvanized Products—Significance of Structures—Methods of Preparing Surfaces for Coating and Their Effects Upon the Mechanical Properties of Steel—Bibliography

By HENRY S. RAWDON[1], M. A. GROSSMAN[2] and A. N. FINN[3]

MOST of the metals used for covering iron and steel as a preventive of corrosion form coatings which are very simple in structure. The metal alloys with the iron of the base to such a slight extent that no change in the microstructure of the resulting coating can be detected, and, in all probability, the behavior of the coating in resisting corrosion is not affected to an appreciable extent. With zinc, however, the case is quite different (15, 16, 18, 21, 23)—particularly is this so in the coatings which are by the application of heat. The zinc alloys with the iron to such a degree that the coating is relatively complex in structure and the properties of such coatings are very appreciably affected. In some coatings (52) certain of the microstructural constituents present may actually accelerate the attack of the metal which the coating is aimed to protect, and the technical literature contains various misleading statements (21) which if correct would suggest that a similar condition may exist in certain classes of zinc coatings.

Theoretical Microstructure of Zinc Coatings

In at least two of the four types, the coating is far from being a simple layer of zinc superimposed upon the base metal beneath, but is a rather complex one, composed of alloys of iron and zinc of various compositions. In order to understand properly the formation of these alloys and their composition, and for purpose of reference, the constitutional diagram of the iron-zinc alloys as modified by Raydt and Tammann (17) is included herewith.

Alloys with an iron content of more than 25 atomic per cent (22 per cent by weight) are formed only with difficulty, usually by melting the constituents under pressure; hence, a structure corresponding to an iron content beyond this point may be disregarded in the discussion of zinc coatings. The constitutional diagram shows four structural fields or layers which are possible in a coating which is allowed to come to equilibrium with the iron base. These are, (1) an outer one (m) of zinc containing a small percentage of iron in solid solution (about 0.7 per cent); (2) a duplex one (m . . . n) composed of a matrix similar to 1 in which are embedded particles of n (a solid solution of a chemical compound $FeZn_7$ with some zinc); (3) a layer composed entirely of the solid solution n, and (4) a duplex layer of two definite chemical compounds $FeZn_7$ and $FeZn_3$—the amount of each compound varies in this field from pure $FeZn_7$ on one side to $FeZn_3$ on the other.

The variations in structure corresponding to the different fields of the structural diagram are illustrated in Fig. 2, which shows portions of the coating produced on an iron wire (16 B. & S. gage) embedded in a block of zinc about $\frac{3}{8}$ in. (1 cm.) square in section by heating for 4 hours slightly above the melting point of zinc (approx. 450 deg. C.). Iron from the wire permeated throughout the zinc block so the resulting coating includes practically the entire block.

Adjacent to the iron is a thin layer, B, of intermetallic compound $FeZn_3$; just outside of this, a much thicker layer, B', in which the definite form of the crystals is plainly seen (this probably contains both $FeZn_3$ and $FeZn_7$); a very thick layer, C, consisting of tiny crystals of the compound $FeZn_7$ in a softer matrix comprises by far the greater part of the coating; the crystals in the outer margin of this layer are particularly well formed and much larger than the average throughout the layer. The outermost portion, D, of the coating shows the characteristic etch-markings of "pure" zinc; these are probably of the nature of Neumann lines; the metal here shows only a few traces of the second constituents; it undoubtedly contains iron, in solid solution, up to its saturation point (0.7 per cent). The nature of the various layers and their behavior during corrosion is discussed below.

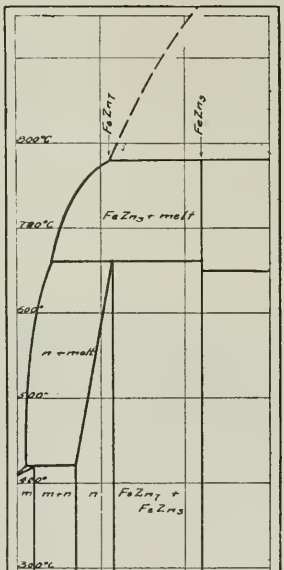


FIG. 1. PORTION OF THE CONSTITUTIONAL DIAGRAM OF THE ZINC-IRON ALLOYS

Variations in Microstructure of Commercial Coatings

a. Hot-Dipped Materials. The variations in structure of this type of coating which may arise in practice are best shown by comparison with the structure when equilibrium is reached, as described above. In general, the same layers are formed in each specimen of this type; the relative amount of each constituent, however, varies considerably according to the conditions of dipping. Fig. 3a shows the structure of a thin coating of this type (galvanized sheet; described by manufacturers as having 1.37 oz. of zinc per sq.ft., i.e., 0.68 oz.

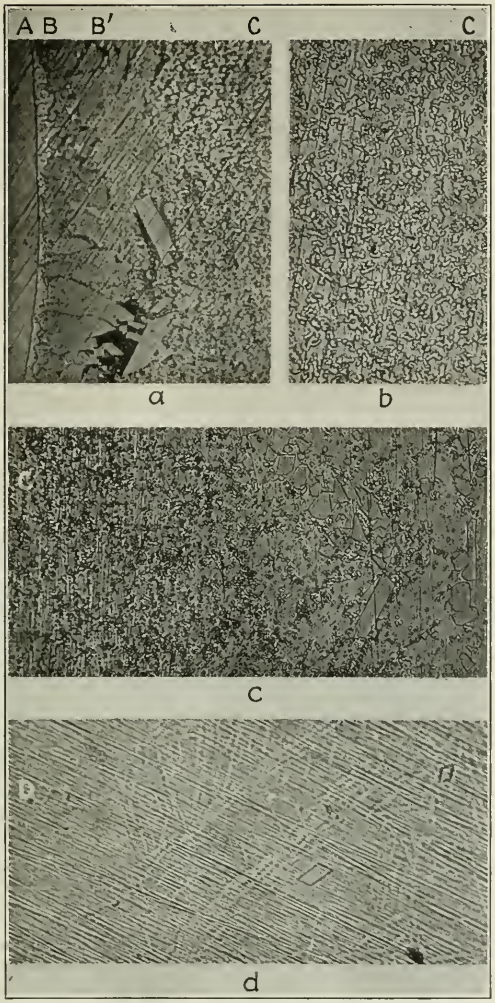

FIG. 2. MICROSTRUCTURE OF ZINC COATING FORMED ON AN IRON WIRE IMMERSED IN MOLTEN ZINC FOR FOUR HOURS

a: *A*. Iron wire. *B*. Alloy layer, $FeZn_3$, adjacent to the steel base. B^1. Layer of the compound $FeZn_7$ (with perhaps some $FeZn_3$). *C*. Duplex layer of crystals of $FeZn_7$ embedded in a softer matrix of zinc containing some iron in solution. × 500. *b*: Intermediate portion of layer *C*. × 500. *c*: Outer portion of layer *C*: the crystals of $FeZn_7$ in the outer portion are large and well formed. × 200. *d*: Outer layer of zinc (containing some iron in solution). The shadow-like etch markings are rather characteristics of zinc. × 200. Etching: 1 per cent. iodine in alcohol was used throughout and for the remaining samples unless stated otherwise.

per sq.ft. on each side). A very thin innermost layer of $FeZn_7$ is to be seen of approximately the same thickness as in the heavy coating (Fig. 3b), which contains 2.5 oz. of zinc per sq.ft. (1.25 oz. per sq.ft. each side). Inasmuch as the thickness of the commercial coating is ordinarily controlled by mechanically adjusting the height of the molten bath relative to the guiding rollers and not by increasing the period of immersion in the zinc, it is to be expected that such would be the case. Fig. 4 shows this innermost layer in a very oblique section of a coating. By holding the article to be coated for a much longer period in the molten zinc, this layer is given a chance to increase considerably in thickness, as is shown in Figs. 5a and 5b, which represents a sample held for approximately eight times as long in the bath as is considered good commercial practice, and a sample which was run through the bath several times in succession.

The intermediate alloy layer appears to be of approximately the same thickness in both the thinly and thickly coated commercial sheets, the difference in the weight of the coating being due to an increase of the outer zinc-rich layers in the thicker coating. (The removal of the excess outer zinc-rich layer in the thin coatings does not allow the crystals of the intermediate alloy layer to form as perfectly as is the case in the thick coatings.) By lengthening the time the molten zinc is in contact with the iron base the relative thickness of the alloy layers is increased—this will be accompanied by a corresponding decrease in the outer zinc-rich layers, particularly in the coatings of sheets and wires, in which the thickness is kept fairly uniform by some mechanical means. The

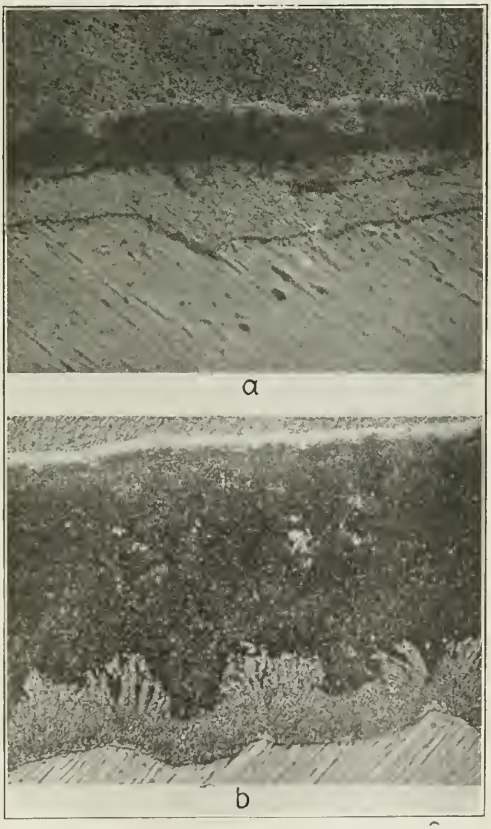

FIG. 3. COMMERCIAL HOT-DIPPED ZINC COATED SHEETS

a: Thin coating; average weight of coating as determined by weighing the sheet before and after dipping 1.37 oz. per sq.ft. *b*: Thick coating; average weight, 2.5 oz. per sq.ft. × 500. All micrographs are arranged (here and following figures) so that the alloy, or inner, layer is toward the bottom of the page.

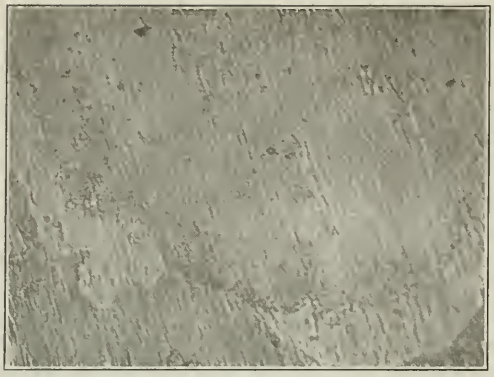

FIG. 4. COMMERCIAL HOT-DIPPED ZINC COATED SHEETS
Oblique section of material of *b*, Fig. 3, showing the inner layers of $FeZn_8$ (white). × 500.

significance of these alloy layers in service is indicated later in this article. The sheets which were held for a considerable length of time in the molten zinc were found, after standing about two weeks, to be spotted with numerous exudations (Fig. 6b). There is nothing in the microstructure to account for this other than some tiny pockets which were apparently filled with inclusions of the zinc and ammonium chloride flux from the bath and which, under the influence of atmospheric moisture, swelled and exuded out of the coatings.

Whether such inclusions of the flux will materially affect the life in service of such coated sheets cannot be stated with certainty from a study of the structure alone. Most of the pits and inclusions, however, appear to be in the outer layers of the coating, and not between the base metal and the coating.

b. Sherardized Coatings. In coatings of this type it is only in those of considerable thickness that any definiteness of structure appears. Figs. 7 and 8 show the structural features which may be expected to occur in coatings of this type.

The nature and composition of zinc-dust mixtures in which the articles are packed for heating probably determines almost entirely the nature of the outer layer; in the innermost layers alloying with the iron base occurs. The outer portions have a characteristic rough and porous appearance and contain a considerable number of inclusions of oxide and any foreign ingredients which may be present in the heating mixture.

The inner portion of this outer layer is much denser than that near the outer surface and has a very characteristic appearance, being broken up by many fine intersecting cracks, caused probably by contraction upon cooling. The layer probably contains a considerable amount of the compound FeZn$_7$. The intermediate layer (Fig. 8b), which easily etches dark, in all probability marks the outer limit of the pronounced alloying of the iron of the base with the zinc of the coating. An extremely thin layer immediately adjacent to the iron base, and apparently of the compound $FeZn_7$, marks the union of the coating with the base metal. In none except very thick ones, e.g., 0.008 in., are these two innermost layers usually found; when much thinner, e.g., 0.002 in. or 0.0015 in., the coating consists entirely of what, in the thicker ones, constitutes the outer layer.

c. Sprayed Coatings (12,13). The variations noted in this type of coatings are of a mechanical origin, due to the nature of the method of deposition, rather than to any alloying of the zinc with the iron base. In Fig. 9 are shown cross-sections of two sheets coated by this process. The coating designated as "one spray" is very irregular and extremely thin in spots. The second sample was described by the manufacturers as a "four spray" coat, but the structure suggests that a coating somewhat heavier than this was applied. The distinct lamellæ which comprise the coat are due to the additional layers of zinc superimposed upon the earlier ones, with some accompanying oxide. Similar features are shown by "sprayed" coatings of other metals.

d. Plated Zinc Coatings. As is to be expected from the nature of the process by which such coatings are deposited, they are essentially of pure zinc and show none of the different alloy layers seen in the first two types. Fig. 10 shows a coating of electrolytic zinc, deeply etched. No indications of structural variations across the section of the layer are to be seen.

The principal point of interest in connection with the microstructure of this type is the variation in

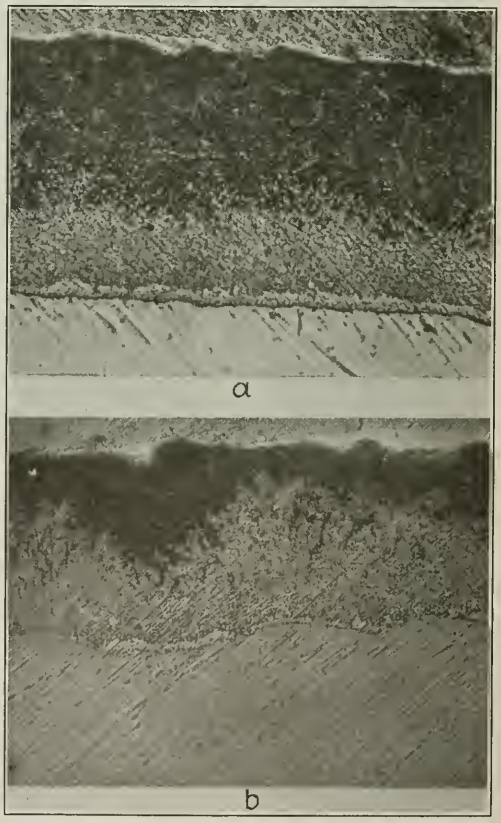

FIG. 5. COMMERCIAL HOT-DIPPED ZINC COATED SHEETS
These were produced under unusual conditions. *a:* Material similar to that of Fig. 3 which was held stationary in the molten bath for two minutes. *b:* Material similar to *a* re-run through the molten bath four times. The alloy layers have been much accentuated by these treatments. × 500.

thickness which may exist on irregularly shaped pieces or even on flat surfaces. Such variations are to be found, particularly in depressions, and on sharp projections where the differences in the current density are considerable. This is especially true for the threaded portion of bolts and screws.

A set of measurements on two similar small machine bolts plated under identical conditions for different periods of time gave the following results:

Weight of Coating Computed From Tank Conditions	Average Thickness, Top of Thread	Average Thickness at Root of Thread
0.20 oz./sq.ft.	0.0157 mm.	0.0038 mm.
0.55 oz./sq.ft.	0.0224 mm.	0.0053 mm.

Fig. 11 shows the variation in thickness of coating on a small article having several sharp corners. The rivet is shown natural size; the thickness of the coating has been magnified approximately 200 times.

Even on flat surfaces the coating is not of uniform thickness. Fig. 12 shows a series of thickness measurements made on sections of a plate 4 in. square, which had been electroplated under very carefully controlled commercial conditions. The sections were cut $\frac{1}{2}$ in. apart, the longer one being taken along a diagonal of the plate. The plate is shown natural size, the relative thickness of the coating has been magnified as indicated. The features described above for electrolytic zinc coatings may be taken as typical of coatings of other metals electrolytically deposited. The microstructure of electrodeposited coatings depends almost entirely upon the conditions of plating, composition and concentration of solutions, etc. (14, 19). Fig. 13 may be considered typical of a normal deposit of electrolytic copper from the commonly used acid-sulphate bath. The variations in thickness of such coatings in very deep, sharp grooves is shown in Fig. 13b. Fig. 14 shows the structure of the copper-clad steel described in the first section of this article.[1] A very thin but definite intermediate alloy layer has formed between the two metals.

Significance of Structure of Coatings

Metallic coatings may protect the metal which they cover in different ways; all coatings afford a mechanical protection against moisture and other corroding agencies. Some metal coatings also by their greater solubility than the base metal protect the metal beneath from corrosion in a chemical way. As previously stated, of the common metals used for coatings, zinc is the only one which behaves in this manner. The significance of the various structures which may occur in different types of coatings should be considered with reference to the bearing they may have upon these two functions which the coating has to perform.

[1] CHEM. & MET. ENG., Vol. 20, No. 9, p. 460.

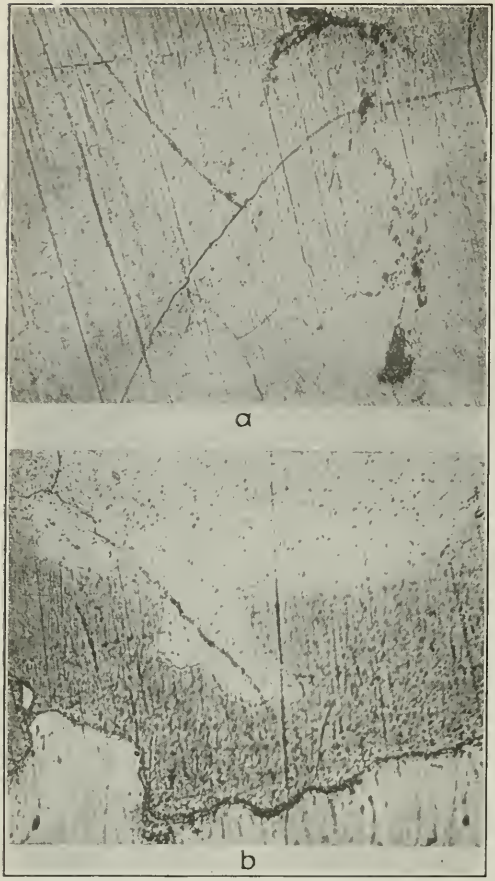

FIG. 8. SHERARDIZED MATERIAL
a: Section of intermediate layer, showing the network of fine cracks and some of the inclusions retained from the heating mixture. *b:* Inner layer, which probably represents the extent of the pronounced outward alloying action of the iron—a very thin film of the compound, presumably $FeZn_7$, lies immediately adjacent to the iron base. × 500.

Various conflicting statements have appeared in the literature concerning the relative electrolytic solution potentials of the different zinc-iron alloys, particularly those which occur in galvanized coatings. The behavior of the alloy layers upon etching indicates that they are electro-negative toward the zinc, i.e., they bear the same general relation to zinc in this respect that iron does. Further than this cannot be stated with certainty from an examination of the microstructure above. Guertler (21) states that the innermost layer ($FeZn_7$) is also more electro-negative to the zinc than is iron, and hence iron will be electro-positive to such a layer; so that when both are exposed to the corroding influences, by the wearing away of the outer layers by mechanical injury, etc., corrosion of the iron will be accelerated by the inner layers. Others have apparently reiterated Guertler's statement, though some have later corrected such statements. The diagram below is constructed from the e.m.f. measurements of the system $Zn - \frac{N}{20}\ ZnSO_4 -$ FeZn alloys (20) and shows that all the alloys behave toward iron in the same general manner as does pure zinc, though not to the same degree. .

Although both of the compounds, $FeZn_7$ and $FeZn_2$, are electro-negative toward zinc, and so will aid in the solution of the zinc when either one is exposed to the corroding agency along with the zinc, it appears that such action is not serious and may safely be disregarded. Fig. 16 shows a section of the coating on hot-dipped galvanized sheet on the exposed and unexposed sides after more than 30 years of service.

The intermediate alloy layer in this material was remarkably well developed—the section of the exposed surface shows that the coating has been quite uniformly corroded away and at the point where the section was taken the inner strata of the alloy layer still remained intact. The claim has been made that zinc coatings containing as large a percentage of the alloy layer as consistent with the mechanical properties desired (freedom from flaking on bending, etc.) are very desirable (35). On account of the lower potential difference between iron and the zinc-iron alloys as compared with that between iron and the pure zinc, those coatings containing the excess of the alloys might be expected to have the longer life in service. Such coatings will, however, not be able to exert protective influence over as large bare spots as will those of much purer zinc.

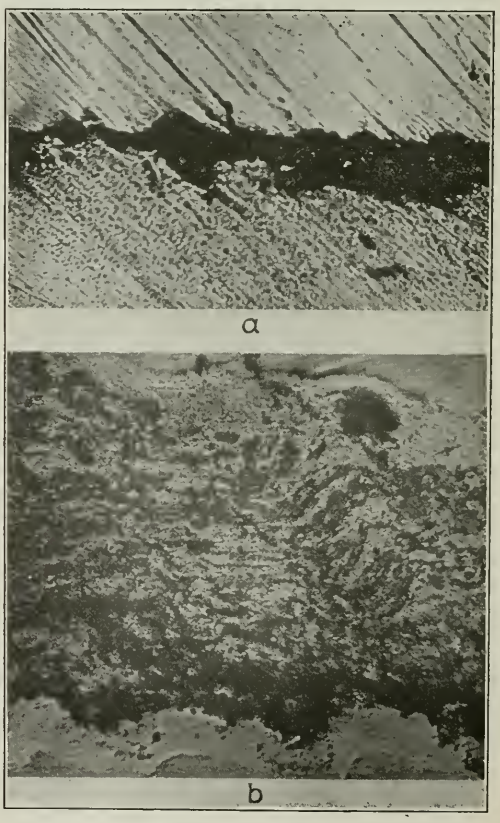

FIG. 9. CROSS-SECTION OF "SPRAYED" ZINC COATING
a: "One spray" coat. *b:* "Four spray" coat. × 500.

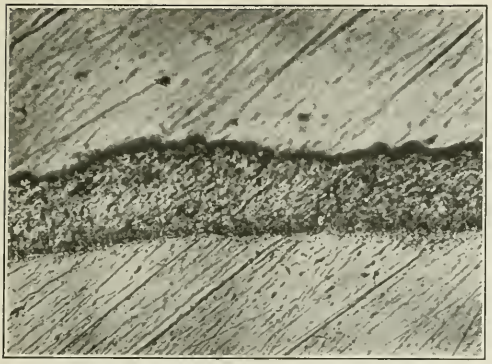

FIG. 10. CROSS-SECTION OF ELECTROLYTIC ZINC COATING, DEEPLY ETCHED WITH 10 PER CENT SODIUM HYDROXIDE. × 500

Inasmuch as these alloy layers are never found in two of the other types, the sprayed and the electrodeposited, the resistance to corrosion of articles covered with such coatings depends entirely upon the thickness of such coatings and on the uniformity of the coating. The variations which may be expected in this feature of these two types of coatings have been discussed above.

Like most intermetallic compounds, the layers of $FeZn_7$ and $FeZn_2$ are relatively hard and brittle. The compound $FeZn_2$ appears to be considerably harder than is the other compound, so that coatings in which it is well developed are easily separated from the base metal, by sharp bending. The fine crystalline condition of the electrolytic and the sprayed coatings probably exerts

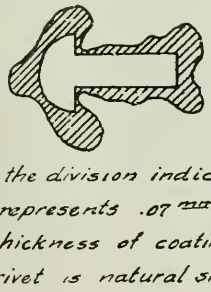

FIG. 11. VARIATION IN THICKNESS OF THE ZINC COATING (ELECTROLYTIC) ON AN OBJECT HAVING SHARP ANGLES

as great an influence as does the absence of any brittle layers in such coatings in preventing them from stripping loose from the base metal as is the case in thick coatings of the hot-dipped type.

Preparation of the Surface Before Coating and Accompanying Effects Upon the Mechanical Properties of Steel

The successful application of coatings to steel requires that the surface of the specimen shall be clean, i.e., free from all oxide and non-metallic material. The general methods of cleaning are: the chemical (63, 64), in which the scale is removed by a direct chemical process of solution; the electrolytic (62, 66), in which the material is made anode or cathode in an electrolytic bath; and the mechanical, in which the scale is removed by abrasion, such as sand blast, tumbling, etc.

The most widely used cleaning process is a chemical one—it is the process of "pickling" in sulphuric acid. It has the advantages of being rapid and inexpensive, of reaching all parts of irregular specimens and of being readily handled by inexperienced operators. In general, the samples are immersed for from 5 to 30 minutes in sulphuric acid of concentration 2 to 15 per cent by weight and at temperatures from 25 to 60 deg. C. Other reagents for pickling include hydrochloric acid, hydrofluoric acid (which is especially useful for cleaning sand castings) and solutions of sodium acid sulphate.

The chief disadvantages of pickling processes are (1) that when the thickness of the scale is not uniform over a specimen, the steel at cleaned portions remains exposed to the action of the acid until the last of the scale is removed from other portions (65), and (2) that there is a skin effect, causing brittleness, which becomes quite pronounced on thin specimens. This brittleness is generally presumed to be due to surface absorption of hydrogen (60, 61).

Experiments have been conducted at the Bureau with

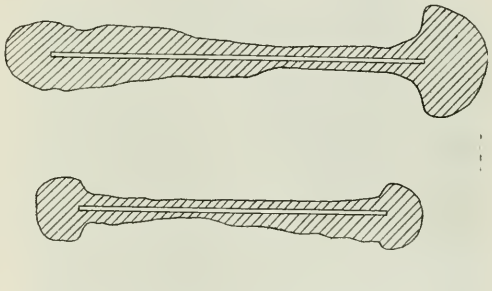

FIG. 12. VARIATION IN THICKNESS OF THE ZINC COATING (ELECTROLYTIC) WHICH MAY OCCUR ON FLAT SHEETS

a view to determining the conditions in the pickling operation that tend to increase brittleness. In a preliminary series of tests on $\frac{3}{16}$-in. wires, specimens variously treated were tested in tension, and the change in percentage elongation taken as a measure of the embrittling effect. The results of these tests seem to indicate that the temperature of the pickling bath has but little influence. Increase of the concentration of the acid increases the brittleness, as does also a longer

immersion period. Heating the samples as in sherardizing (375 deg. C. for 4 hours) removes the embrittling effect. Heating as in hot galvanizing (450 deg. C. for 2 minutes, though 2 minutes is considerably longer than the average practice) partially removes the brittleness. It has been stated that heating at 225 deg. C. for 6 hours removes the embrittling effect altogether. Further experiments are in progress at the Bureau, in which wires are being treated by various methods and then tested in impact and alternating stress.

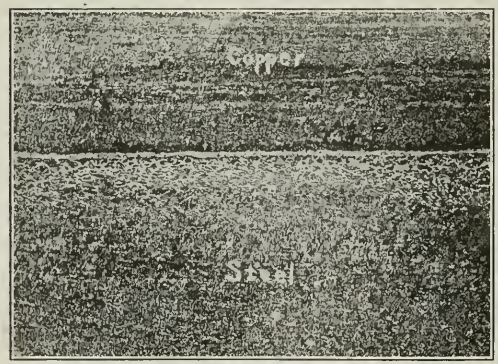

FIG. 14. COPPER-CLAD STEEL

A definite alloy layer has formed between the two metals. × 500. Etched with concentrated ammonium hydroxide followed by a 2 per cent nitric acid.

In the electrolytic method of pickling (62, 66), the sample is placed as cathode or anode in an electrolyte through which a current is passed. When the steel is the cathode, the hydrogen liberated there reduces some of the oxide scale and also aids mechanically in flaking off much of it; when the steel is the anode, the

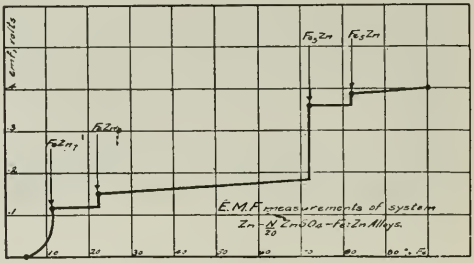

FIG. 15. E.M.F. MEASUREMENTS OF THE SYSTEM Zn — $\frac{N}{20}$ $ZnSO_4$ — FeZn ALLOYS

oxygen there liberated mechanically detaches the scale, which later may dissolve in the electrolyte. The concentration of hydrogen at the cathode would be expected to cause more brittleness, as compared with the anode, and experiments made elsewhere have shown that samples cleaned at the anode are much less brittle (61).

Of the mechanical methods of cleaning, the sand blast is the one most widely used. The strong stream of sand particles abrades or chips off the particles of scale

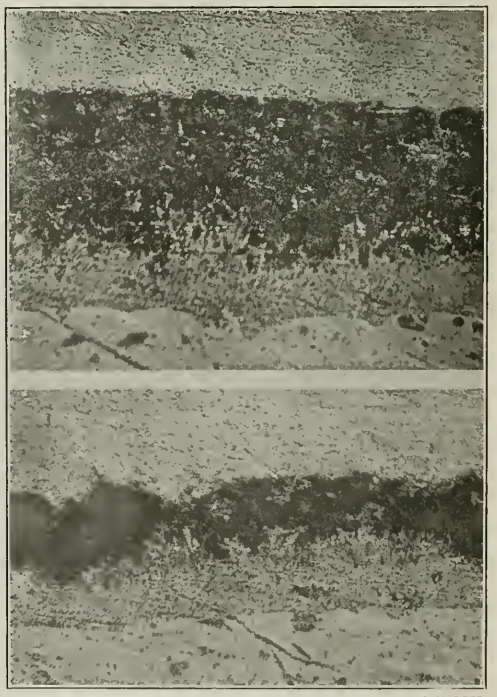

FIG. 16. STRUCTURE OF HOT-DIPPED SHEET WHICH STOOD MORE THAN 30 YEARS' SERVICE

Above: Coating from the inner or unexposed surface. Below: Coating from the outer or exposed surface. × 500.

from the steel. The method gives a smooth, bright surface, but takes more time than pickling and does not satisfactorily reach crevices. Steel shot and crushed steel are said to have some advantages over sand. It must be remembered that the "cold-work" of impact will cause hardening of the surface, which may be quite noticeable on thin sections and sometimes quite harmful.

Another process of mechanical cleaning consists in "tumbling" the specimens in a rotating barrel, with emery and water. It is an abrasion process. A similar method, used on small articles, involves rolling with emery and oil, between rollers. It is the mildest process of mechanical cleaning, and while quite slow it has advantages for springs and the like, in that it avoids both the brittleness from pickling and the hardening from the sand blast.

Hand Device for Flotation Experiments*

By Will H. Coghill
Metallurgist of the Bureau of Mines

In flotation experiments it is desirable to have a hand device correlating successively with the experimental and commercial machines. This phase of flotation has not been sufficiently developed. It is the purpose of this paper to describe a device which is intended to fill this gap.

Success in designing a machine depends upon the principles selected to govern its detail. The principles laid down to guide in the selection of this device are: The pulp density, and the ratio of solids to frothing surface, must be the same as in well designed machines.

The importance of these factors can best be emphasized by quoting from Del Mar.[1]

"Under manipulation may be included the shape or form of the collecting-chamber of the flotation machine, for the cells in any flotation system are used for two purposes, either to float a dirty concentrate, which must be cleaned before marketing, or to float a finished concentrate, which is ready for shipment. In the former case the collecting chamber of the machine should favor a quick discharge, that is, there should be a narrow chamber, but when we require a finished product the box must be sufficiently wide to allow the settlement of occluded waste or gangue. Manufacturers of flotation machines miss this point and therefore the same machine is often used for roughing and for cleaning, while the two operations require entirely different manipulation. This important structural feature in the flotation-chamber may make the difference between success and failure, for not only must a concentrate be produced, but it must attain a certain grade of metallic content to be fit for shipment."

Consistent Proportions

On observing successful laboratory flotation machines of the mechanical agitation type we find that when the pulp density is 3 to 1, there is from 30 to 60 grams of ore for every square inch of frothing surface.

Let us see now if the test tube, which was recommended a long while ago, has proportions that are consistent.

Take a test tube of such a diameter that it gives a frothing area of 0.6 sq.in. The quantity of ore required is then, say, 30 grams, and for a 3 to 1 pulp, 90 cc. of water must be added. But the ordinary test tube of this diameter will hold only 85 cc. of water. It is eight inches long. We see then that after making allowances for the volume of ore and air, the test tube would have to be about a foot long.

It is obvious that the adoption of these proportions in such a device would not be consistent. A loaded bubble which chanced to be at the bottom of the tube at the end of the agitation period would have to travel upward a distance of nearly 12 inches against a falling column of solids before it could deliver its burden to the froth. Needless to say, it would be wrecked at the outset and buried beneath the column of ore.

Moreover, the test tube has no facilities for discharging the froth.[2]

The device which is recommended here has been used at the Northwest station of the U. S. Bureau of Mines at Seattle. It consists of two pyrex flasks, one of 250 cc.

and the other of 500 cc. capacity. A rubber nipple is placed on the neck of the smaller one so that when the flaring portion is ground off it will fit snugly into the larger as shown in the photograph.

To prepare a test, the smaller flask is filled with a mixture of ore and water of the desired consistency and emptied into the larger one, after which about three cc. of water is added. After the desired flotation reagents have been added a stopper is placed in the flask and we are ready to proceed with the test.

The procedure of testing is by means of hand agita-

[1]Del Mar, Algernon, "Differential Flotation of Lead and Zinc Sulphides." *Min. and Sci. Press*, Vol. 117, Nov. 23, 1918, p. 692.

[2]The separatory funnel which has been recommended by "A Special Correspondent," *Min. and Sci. Press*, July 24, 1915, p. 122, and by Ralston, O. C. and Allen, Glenn L., *Min. and Sci. Press*, Jan. 8, 1916, p. 44, is faulty because the proportions are not good and the froth has to stand until the tailing is removed

tion for, say, five minutes. The stopper is removed, the flasks are united, and, after a brief agitation, placed in the position as shown. The extra three cc. of water referred to elevates the lower level of the froth so that it will overflow into a collecting pan when the larger flask is removed. The agitation may be repeated as often as desired by adding a little extra water each time.

The efficiency of course is low as compared with the mechanical devices, but the relative floatability of minerals and relative effects of flotation reagents may be quickly determined.

There are two reasons why the efficiency is low: first, there is no opportunity for the froth to build up during the agitation period; second, a small quantity of gangue lodges on the bench formed by the union of the inner and outer tubes, and by joining the overflow reduces the grade of the concentrate.

The quantity of modifying reagents must be determined by calibrated devices. Otherwise impressions may be misleading. This is demonstrated by the following example.

When four drops of oil was added from a medicine dropper the pyrite floated so freely that the results were adverse. The dropper was then calibrated and it was found that four pounds of oil per ton of ore had been used. The test was then repeated with one drop of oil and the results were encouraging.

This device, then, has three points of advantage over the test tube: It has convenient discharging facilities, and it provides for desirable pulp densities and a consistent area of frothing surface.

Improved Form of Granular Carbon Resistance Furnace for Fusion Point of Coal Ash and Firebrick

By C. H. Lovejoy

A GRANULAR carbon resistance furnace of the type described in Bulletin 129, U. S. Bureau of Mines, "The Fusibility of Coal Ash and the Determination of the Softening Temperature," has been in use for several years at the Pittsburgh Testing Laboratory, Pittsburgh, Pa. In building a new one last summer, several improvements were added, to facilitate operation and the replacement of worn parts. The furnace was built at slight expense from standard fittings, with very little machine shop work necessary.

In the sketch *D*, the base, was made from an old automobile brake drum housing, filled with a mixture, *B*, of broken firebrick and fireclay.

A-A are made in the laboratory from alundum cement, and baked on the hot plate.

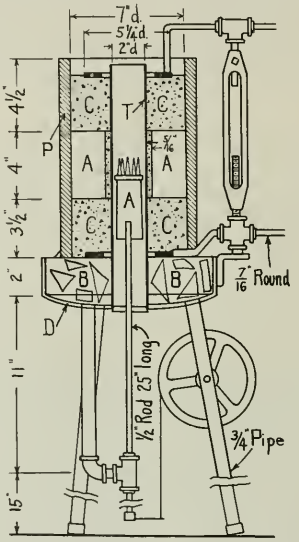
P is a 12-in. length of vitrified clay pipe, with a layer of 20-gage galvanized sheet iron covering the outside.

T, the central tube, is made from 2-in. lengths, $\frac{3}{32}$-in. thick, manufactured by the Norton Co., Worcester, Mass., of No. 288 alundum.

C is granular carbon from the National Carbon Co., Cleveland, O., passing 8 mesh and held on 40 mesh.

The lower wrought iron circular terminal is put in place, the shell *P* set over it, and the lower $3\frac{1}{2}$ in. of carbon poured in. Next the heavy ring, *A*, is placed, the rest of the carbon added, and the top terminal clamped into position. The turnbuckle was intended for bringing the top terminal into close contact with the carbon, but was not found practical, so a set screw was put in the top of the turnbuckle, as shown in the sketch. Of course the terminals are insulated from the iron with hard rubber plugs.

The furnace operates on a 110-volt a.c. line, protected by 100-amp. fuses, and controlled by a 100-amp. 42-point rheostat in series. The furnace is started at about the eighth point, at which the constricted zone should come to a dull red heat in $\frac{1}{2}$ to $\frac{3}{4}$ hr. Now raise the plunger to the top of the furnace by turning the hand wheel, and place on it the alundum pat which carries the Seger cones together with the test cones made from coal ash and dextrine solution. Lower the plunger very, very slowly, giving the dextrine a chance to burn out. Advance the rheostat two points every five minutes until the coal ashes have fused, and estimate the temperature by comparison with the condition of the Seger cones. The plunger may now be raised and the pat with cones removed for closer observation.



Advantages of This Furnace

If this furnace were used for coal ash fusions alone, it would last indefinitely. It is used, however, for fusion points of firebrick up to temperatures of 3000 to 3200 deg. F., at which points the central tube is liable to crack and warp, or the heavy ring, *A*, to fuse. After the furnace has cooled it is a simple matter to remove the rings, beginning at the top, letting the carbon fall through the central tube, and replace the spoiled parts. The carbon in the lower portion lasts indefinitely; that in the constricted zone gradually burns to ash, and should be discarded whenever parts are replaced.

The ease of introducing cones into the furnace and removing for examination, and the possibility of raising or lowering them at any time to the hottest level, has proved to be a great advantage. The increased height of furnace has prevented the iron terminals from becoming too hot, and the solid ring, *A*, stays in place well, yet can be removed when necessary.

Pittsburgh Testing Laboratory.
Pittsburgh, Pa.

Chemical Specifications

By Wallace P. Cohoe

GENERALLY accepted specifications for the purchase of standard chemicals have been and still are lacking, while the development of chemical trade emphasizes the need of them. If sales of sulphuric acid constitute an index of industrial progress, then trade in other chemicals must augment the sign, for even reference to materials by their chemical names shows a certain understanding of what they are. It is also usually an indication of industrial advancement to find that wares are bought on specification. It shows greater information on the part of the buyer, a larger comprehension of his business; while familiarity with specifications by men engaged in trade may be cited as evidence that they know what they are about.

Of course, contracts for chemicals at the present time are made in accordance with definite specifications, but it does not follow, because Brown purchases from Adams 100 tons of 60 deg. pickling acid, and Jones purchases 100 tons of 60 deg. pickling acid from the same Adams, that both buy according to the same specifications. Probably Brown and Jones are using pickling acid for much the same purpose, but their chemists have slight differences of opinion. In this case, Adams, who sells the acid, will be obliged to make two very slight modifications or to supply the same product to each, trusting that he will not be criticised. Both Brown and Jones will probably be satisfied with what they get, but in order to secure any specification whatever the purchasing agent of each must go to the chemist of each and thus two different specifications are born.

This increasing diversity might continue indefinitely were it not for the fact that large consumers, by their great tonnages, actually do fix a type to which the manufacturer is bound to be held in the main. He cannot make a large variety of products without asking a premium for them. If the purchasing agents of various firms had in their possession standard specifications for pickling acid, to still keep to our example, then the problem as regards both the manufacturer and the customer would be simplified. Trade specifications of standard chemicals do exist. Is there any reason why, in most cases, they should not be generally known?

Trade Secrets Legitimate and Here to Stay

Trade secrets are legitimate and there is no use in thinking that specifications will do away with them or that after peace is declared, even though we be destined to live under some new and reformed system of government, we shall know them no more. Trade secrets consist in information that has not become public, and it is not consistent with human nature to reveal that which it is profitable to keep secret. No kind of rule or law can make persons tell everything they know. If anybody doubts this he should visit the library of Cornell University and peruse the torture records which are to be found there.

Trade marks are of value in the case of preparations of secret formula, but in the case of chemicals of known composition the value of a trade mark consists not in putting over something worth a little at a high price upon an unsuspecting or unintelligent buyer, but rather as a mark or guaranty that the goods bearing it shall represent full value.

We are looking forward to big business in chemical industry. There is big business in securities, metals, grain, cotton and all standard merchandise. With the exception of stocks and bonds they are all graded, and daily market quotations giving quantity and price and quality are available. Chemicals are quoted as to value and quantity, but the qualities mentioned in these quotations are vague; they lack the generally recognized standards, such as may be found in regard to cotton, wheat, coffee, etc. We see no immediate need for a Chemical Exchange, but we do see a need for chemical standards. Standardization is necessary before an industry can get into the great brotherhood of trade.

Quality standards are required for a number of purposes. For instance, suppose a shipment of a thousand drums of 76 per cent caustic soda is received and stored. A warehouse receipt is given and a bank lends money on it. Is it electrolytic or made from soda ash, or is it bottoms? The bank does not know, because the warehouse receipt does not tell unless it is accompanied by a satisfactory certificate as to quality. The same holds good as to insurance adjustments. Suppose several carloads of naphthalene are received and made collateral for a loan. Is it prime white, white, or yellow flakes? There may be a difference of 50 per cent in value which the warehouse receipt does not disclose.

An Example for Illustration

Some time ago a firm bought a considerable quantity of potassium permanganate from a dealer. Examination proved that it contained more Glauber's salt than $KMnO_4$. The dealer from whom they bought it set up the claim that he had purchased it in the market and that in point of fact it was potassium permanganate. It was not guaranteed to be free from impurities, nor was there any specification as to what it might or might not contain. The purchasers were left without recourse. Of course, it may be said that it should have been bought on sample and the sample tested. But this need for checking and counter-checking does not make for good trade practices. There is plenty of work for chemists to do in industry besides unnecessary checking up. The word of a responsible manufacturer should be proof of assay when standards are known.

Specifications are also required to make up a correct balance sheet. It is always good policy to be conservative in the valuation of assets, but it is very bad bookkeeping to record assets as something that they are not. It is nothing less than what Wells calls "economic uncleanness" to make incorrect statements even in the interest of conservatism. Judgment may be availed of in affixing prices, but it has no place in listings.

Buyers used to take what they could get. Commercial oil of vitriol was every color from dark brown through various shades of red and pink to nearly water white. It contained arsenic and lead sulphate and iron, but so long as it was 60 or 66 deg. B., the specifications were fulfilled. Now the specifications as to this chemical alone are so diverse and multitudinous that we shall make it later the subject of a special article. The same holds true of nitric and muriatic acids and of soda.

Industry Must Know What It Buys

Chemical industry must know what it buys. Of course, by going to certain manufacturers a buyer can know what he is getting, but factors of location and market often make such a choice impossible. There are many men of many minds engaged in industry and they display vast differences in their several conceptions of trade ethics. The overzealous salesman also is much

better off if he is held to specifications, even though this at first may almost seem to break his spirit. Granted favorable physical and economic conditions, industry will thrive best wherever technical conditions are best known; and the use of and familiarity with specifications is a function of good technology. Establishments that maintain adequate chemical control do know what they buy, but the lack of known standards among sellers makes this task often difficult and it frequently increases costs far beyond what they should be normally.

The problem of standards in the colloidal field is a difficult one, but it is not beyond the range of possibility. We have, for instance, in this country a great variety of clays available for porcelain and pottery and for coating paper. It may be said without fear of contradiction that there is a disposition among American producers to favor the sale of quantity rather than of quality, and that refined and matured clays might be made available if greater efforts were made to prepare them. The fact that chemical analysis has little value in determining their quality has no bearing upon the subject. Specifications may indicate geologic history and treatment in refining and maturing as well as prohibitions as to the presence of undesired bodies. If such specifications were available, many clays now urgently needed might be obtained from domestic sources. This would be good for our ceramic industries as well as for the paper industry. We do know of one large buyer of clay who has succeeded in so standardizing his physical and chemical tests that he is able to write a specification which will represent the qualities desired.

Demands Will Be Met

Dr. B. C. Hesse investigated on behalf of the U. S. Department of Agriculture the dyes which might be allowed in food products. His work involved not only the study of the constitution of the colors themselves and their effects upon the human system, but also a study of the inorganic impurities which may be present in them, of the chemicals that entered into their manufacture and the possibility of traces of arsenic, copper, lead, etc. This might be called a work of super-refinement or meticulous caution, but it is typical of the scholarship that will insist on having its demands met, either by American or foreign manufacturers.

I have in preparation a book on chemical specifications to be published by the McGraw-Hill Book Co. The task of getting together the material which is now well under way has presented some difficulties, although in the main my inquiries have met with generous responses from manufacturers.

Examples of Trade Specifications

In order to illustrate what I mean, I add a few examples of existing trade specifications, concerned with chemicals mostly below the first rank in importance. These are given as in actual use by reputable firms. They are given also in the hope that they may if possible promote discussion and receive comment to the end that greater enlightenment on the subject may prevail.

Acetic Anhydride:

Commercial form: Colorless liquid.
Boiling point 130 deg. to 140 deg. C.
Contains not less than 60 per cent acetic anhydride and not more than 40 per cent glacial acetic acid.
Contains not more than 0.1 per cent chlorine.
Contains not more than 0.1 per cent sulphur.
Delivered in carboys.

Commercial Acetone:

Colorless liquid.
Consists chiefly of acetone, methyl alcohol and methyl acetate derived from crude wood alcohol.
Contains not less than 55 per cent of true acetone by the Messinger test.
Delivered in steel drums.

Commercial Tannic Acid:

Commercial powder, yellow to brown in color.
Average commercial purity of 80 to 88 per cent.
Clearly soluble in water and 20 per cent acetic acid.
Moisture 12 per cent.
Ash 2 per cent.
Put up in barrels of 350 lb. net.

Ammonium Chloride:

White crystalline solid.
Average commercial purity 99 per cent.
Packed in form of powder, which must be free from grit or other foreign substance.
Must be white or nearly white in color.
Must contain at least 98.1 per cent ammonium chloride on dry basis.
Must not contain more than 1 per cent known volatile impurities.
Moisture, not more than 0.25 per cent.
Pyridine, not more than 0.005 per cent.
Thiocyanates, not more than 0.01 per cent.
Must contain no trace of acidity or of phenols.
Packed 250 lb. to a barrel 19⅝ x 30 in. with crêpe paper lining.

Carbon Tetrachloride:

Colorless liquid.
Boiling point, 75 to 76 deg. C.
Sp.gr. 1.596 at 15 deg. C.
Average commercial purity, 98.5 per cent.
Allowable impurity not more than 2 per cent. of CS_2.
Packed in 55 or 110 gal. drums.
Extra for packing and shipping in carboys or bottles.

Naphthalene:

White crystalline solid.
Melting point, 79 to 80 deg. C.
Boiling point, 218 deg. C.
Should boil off within 1 deg.
Should be white and volatilize without residue.
Must not become dark colored when agitated with concentrated sulphuric acid.
Should not contain phenols or quinoline bases.
Crystals should be dry and rattling without adhering oils.
Packed in ordinary barrels containing 200 lb. with brown paper lining.

Potassium Permanganate Commercial:

Commercial crystal.
Color, bronze to steel blue.
Commercial purity average 96 to 99 per cent $KMnO_4$.
Allowable impurities are small amounts of KCl and MnO_2 derived from the process of manufacture.
Unallowable impurities—sulphates.
Packed in cans or drums in accordance with the I.C.C. regulations regarding oxidizing materials.

Sodium Cyanide:

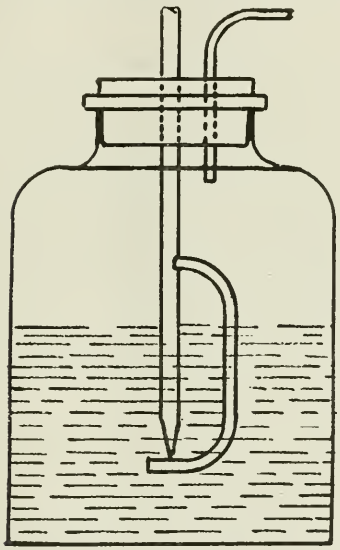
Commercial 96 to 98 per cent pure white crystalline lumps.
Melting point 560 deg. C.
Boiling point above 800 deg. C.
Sp.gr. 1.53.
Should contain 96 to 98 per cent NaCN.
Impurities 2 to 4 per cent.
Allowable impurities—carbonates, hydrates or cyanates.
Unallowable impurities—chlorides and sulphides.
Packed in tin lined boxes or sheet iron drums, hermetically sealed.

Sale of Picric Acid Plant

Bids on the Government picric acid plant at Brunswick, Ga., will be opened May 20. The plant consists of a 2000-acre tract on which are located all the buildings necessary for its operation. Prospective bidders will be given all the facilities for inspecting the property by applying to the Cincinnati District Salvage Board, Cincinnati, Ohio.

Synopsis of Recent Chemical and Metallurgical Literature

Determination of SO_2 in Gases.—In the determination of sulphur dioxide by the iodine method, the chief error encountered is the tendency to rush the gas through the iodine solution too quickly for the interaction between the SO_2 and iodine to be complete, with consequent erroneous results. To overcome this difficulty MR. O. D. BURKE (*Chemical News and Journal of Physical Science*, Dec. 6, 1918) used the following apparatus: A narrow glass tube is drawn out at one end into a very fine capillary, which is ground level at the point or end. Another glass



APPARATUS FOR DETERMINATION OF SO_2 IN GASES

limb is fused on to the straight limb and extends downward to just beneath the capillary, where it is flattened out and the top surface ground. The capillary is made to fit tight on the flat ground surface of the second limb. In this way the gas passing through the capillary tube is broken up into very fine bubbles no larger than a pin point; also the space is so restricted for the passage of the gas that no rushing through can take place, and the time interval for the passage of a certain volume of gas is identical in all cases, thereby with just ordinary care insuring extreme accuracy. This apparatus will prove a valuable addition to laboratories where SO_2 and many other gases are to be determined accurately.

Oxygen as a Revolutionizer of Industry.—The recent extraordinary progress in the industry of nitrates, based on the fixation of atmospheric nitrogen, is accompanied by the production of cheap oxygen as a by-product. In a paper read before the Société de l'Industrie Minérale, M. F. LAURE outlines the importance of the part this cheap oxygen will be called upon to play in the development of industry (*Bulletin et Comptes Rendus* de le Société de l'Industrie Minérale, 3éme livraison, 1918).

Besides the existing industries using oxygen, such as autogenous welding, manufacture of precious stones, metal cutting, medicines, etc., the following new uses are in view. Gas lighting will be revolutionized, as a Welsbach lamp using illuminating gas admixed with oxygen will give a light intensity of more than ten times that obtained when using only illuminating gas. Hence new forms of burners and economy of fuel will result. In metallurgy oxygen admixed to the air blown into the furnace will increase considerably the temperature and the efficiency of fuel, and also permit the use of cheaper qualities of fuel. Calcium carbide will be produced in blast-furnaces by purely thermic methods. Alumina will be reduced by carbon. Auriferous quartz will be melted. The glass industry will be revolutionized by the easy fusing of all forms of quartz. The thermal efficiency of the use of coal will be so improved that a new chemistry intermediary between the old chemistry and the chemistry of the electric furnace will be created. The manufacture of sulphuric acid will be much accelerated by a powerful oxidation of sulphurous acid. The cheap production of ozone, or electrified oxygen, will enable its greater use, notably for the sterilization of drinking water and the maintenance of a practically constant purified atmosphere in homes, public places, factories, mines, etc.

Scarcity of Raw Materials in Germany.—How hard it is on the German industry to keep up with the conditions of having the raw materials supply cut off is shown by the following few examples: For copper, they use a cupriferous schist of 0.7 to 1 per cent copper, instead of the previous 2.5 per cent. For lead, a variegated sandstone containing some lead carbonate, which before has been considered useless, is now worked, although it entails a loss of 40 to 50 per cent in lead. For aluminium they use a poor quality of bauxite and even clay. Wolfram is now obtained from wolframite with 0.06 per cent instead of the former 1 per cent wolfram. Vanadium is recuperated from slags with 0.7 per cent vanadium. Their present supply of chrome is a chrome ore of 24 per cent Cr_2O_3 instead of the former 48 per cent ore. Nickel and cobalt are obtained from waters pumped out of mines in which they are dissolved. For sulphur they use a 41 per cent pyrite instead of the former 52 per cent, also gypsum and anhydrite. They work phosphates with as low as 20 per cent content instead of the former 80 per cent (*Métaux, Alliages et Machines*, Mai, 1918). There is no doubt that the metallurgical improvements required under such conditions will be ultimately of a general benefit to the efficient use of the present mineral wealth.

Recent Progress in the French Chemical Industries.—Besides the progress realized during the last few years in the pre-war existing industries, special attention has been given to the manufacture of products heretofore imported from Germany. Among these the most important are: The production of magnesium, asbestos and rubber jointing materials, permanganate of potassium, pentasulphide of antimony, sulphide of sodium, which has replaced the sulphide of arsenic in tanneries; polishing powders for metals,

glass, aluminium, bleaching liquids (extracts of javel), calcium carbide, etc. The production of sulphuric acid has increased from about 850,000 tons per year in pre-war times to about 2,000,000 tons per year, and 3000 tons per year of oleum, and is still on the increase. The manufacture of nitric acid has increased from about 12,000 tons per month to about 50,000 tons per month. The production of hydrochloric acid has grown to such an extent that there is now available a great surplus, and the liquid chlorine industry, which was nil before the war, is now capable of manufacturing about 15,000 tons per year (*Génie Civil*, Nov. 9, 1918).

Water-Power Resources in Norway.—The following is an abstract of a paper published in the *U. S. Commerce Reports* of March 13, 1919. The power available for development in Norway is estimated at about 15,000,000 hp. The utilization of this water power on a large scale started about 15 years ago, and by this time it is estimated that 1,300,000 is used. The State has bought a great number of waterfalls in all parts of the country, with the intention of electrifying the State's railways. Of the 1,300,000 hp. already developed, 1,100,000 is in private ownership and 200,000 belongs to different communities.

The main Norwegian industries depending upon hydro-electric power are: The saltpeter industry, mostly in the Telemarken district of Southern Norway. More than 300,000 hp. is used for making nitric acid, Norwegian saltpeter and other nitrates and nitrites. The manufacture of calcium carbide is the oldest electrochemical industry of the country, and the production is growing yearly, necessitating the construction of several plants at different places. The present yearly production is about 100,000 tons. The American company has a concession to use 84,000 hp. in the district of Stavanger, and a large plant for utilizing this power is now being built. The several ferrosilicon plants produce about 30,000 tons per year, and the production of ferro-alloys, aluminium, zinc and similar products is continuously increasing. Norway possesses more water power in proportion to its population than probably any other country. The developed horsepower per capita is larger than in any other country—more than 0.5 hp. for every person in the country.

Treatment of Waste Liquors From Paper Pulp Mills.—The solution of the problem of converting factory waste into valuable by-products has enabled more than one industry to prosper in the face of severe competition. While conditions have not reached this point in the paper industry, the problem is nevertheless an important one because of the enormous tonnage of waste.

As has been the case in other industries, the first steps were taken, not with a view to the recovery of valuable material, but because of legal difficulties arising from older practices[1]. Thus in England prior to 1876, the waste liquor was allowed to flow into the streams. The introduction of the rivers pollution act compelled the paper manufacturers to adopt other methods for the disposal of their waste. It was soon found that, by evaporating the liquors to dryness and calcining the residue, from 90 to 95 per cent of the alkali used could be recovered in the form of carbonate. While this treatment was satisfactory in that it conformed with the law and at the same time permitted the recovery of alkali, it was inefficient from the standpoint of by-product recovery, as only the inorganic material was reclaimed. It has been pointed out[2] that, for every ton of dry pulp made, a ton of organic matter is discharged with the waste. As soda and sulphite pulp production in 1914 was 1,500,000 tons[3], the value of utilizing the organic material is self-evident.

During the last few years, several developments have been made along this line. Alcohol has been produced by fermenting the carbohydrates in neutralized sulphite liquor.[4] In Sweden, the lignin is precipitated and used as fuel.[5] The neutralized liquor has also been evaporated and used as a binder for roads, briquettes and as a tanning material, under the name of glutrin[6].

Recently, a number of patents have been granted which are assigned to the West Virginia Pulp & Paper Co.[7] and which indicate some of the possibilities of research in this field.

Black liquor from the caustic soda process of producing pulp is concentrated in multiple effect evaporators until the water content is about 50 per cent and the sp.gr. 1.32. In some cases, as when working with sulphite liquors, it may prove advantageous to add a small amount of caustic soda during the concentration process. About 50 per cent of quicklime is now added to the liquor in a rotary mixer. The slaking of the lime evolves sufficient heat to convert a portion of the water into steam, which in escaping renders the mass porous. Also the sodium compounds are causticized.

This porous causticized calcareous ligneous acetate material, which is termed calignate, weighs only 38 to 40 lb. per cu.ft., whereas the true specific gravity of the material is 1.9. Its strength under compression is from 612 to 987 lb. per sq.in., and the material will retain its form up to 500 deg. C.

Distillation of calignate in a revolving retort at 600 to 700 deg. C. in the presence of superheated steam yields acetone[8], along with other ketones, heavier oils, ammonia and fixed gases which may be used as fuel. When calignate is made with black liquor from poplar wood, yields of acetone and methyl alcohol up to 5 to 10 per cent of the weight of organic material present have been obtained. Leaching the residue with water recovers the sodium hydroxide, while heating in a rotary kiln converts the final residue into quicklime.

Calignate is heated to 250 deg. C. in a closed retort so that methyl alcohol, moisture, etc., are driven off, without, however, decomposing acetates present. The mass is cooled in the absence of air, extracted with hot water, and the resulting solution concentrated to 30 to 32 deg. B. Carbon dioxide is passed into the solution and the $NaHCO_3$ which crystallizes out is filtered off. The solids in solution now contain sodium acetate, 50 per cent; sodium and potassium salts of lactonic acids, 25 per cent; black coloring matter, 10 per cent; $NaHCO_3$, 5 per cent; NaCl, 10 per cent. The sodium acetate amounts to 10 to 12 per cent of the weight of the calignate. After neutralizing the solution with acetic acid, the coloring matter is precipitated with lime and the sodium acetate recovered by evaporation and crystallization. The sodium acetate in the mother liquor is

[8] Cf. CHEM. & MET. ENG., XX, 190.

decomposed with an equivalent amount of H_2SO_4, the Na_2SO_4 crystallized out and the acetic acid distilled off.

The lactonic acids may now be recovered either as their alkali salts or as the free acids.

When waste sulphite liquor is digested for several hours with 2 to 6 per cent of caustic alkali in a rotary digester under 80 to 100 lb. pressure, the woody material is converted into lignin and some of the sugars present are apparently transformed into lactonic acids which give acetone and other ketones and alcohols on distillation.

The precipitation of the lignin in a form which can be easily filtered is facilitated by passing in carbon dioxide. The lignin represents about 30 per cent of the dry weight of the organic matter in the original liquor and may be used as a tanning material or as an inert filler for paint, linoleum and other products. The filtrate may be converted into calignate by the method outlined above.

Specifications for Leather Belting.—In view of the quantity of leather belting used in the industries for the transmission of power, it seems remarkable that practically no specifications exist which are applicable to modern practice. That such is the case, however, is pointed out by HARRY A. HEY in *Industrial Management* for April, 1919, and he endeavors to supply the deficiency by outlining a set of specifications which has been in satisfactory operation for the purchase of a large amount of belting during the past three years.

In drawing up these specifications, due consideration has been given the fact that the raw material itself is of a variable nature and that, during manufacture, the human element is introduced to a greater extent than in many industries. Furthermore, the requirements should cover the best commercial practice and no more, lest they defeat themselves through the inability of manufacturers to live up to them.

1. These specifications are intended to cover first-quality, center-stock, oak-tanned leather belting for general use. Previous specifications are hereby cancelled.

2. The material and workmanship must be guaranteed by the vendor to be of the highest quality and the finished product equal in strength, pliability, durability and performance in use to any obtainable.

3. The purchaser reserves the right to subject each roll of belting when received to the following tests. Failure to pass any of them will be cause for the return of the entire roll for full credit, plus carrying charges both ways. The manufacturer's name and brand must be stamped on all belts every ten feet and the length every foot.

4. When unrolled freely on a flat surface, without tension, the belt must lie flat at all points and be full length as marked. There must be no evidence of injurious surface blemishes, artificial finish to produce high polish, shimming or excessive leveling, cracking when bent grain side out through 180 deg. over a $\frac{1}{2}$-in. diameter rod for single belts and a 1-in. rod for double belts, or piping when similarly treated grain side in.

5. No section shall be longer than 54 in. or shorter than 42 in., including laps, except in double belting, where shorter pieces may be used provided they do not exceed 10 per cent of the total number of laps.

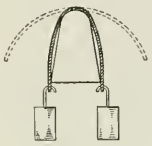
6. (*a*) Thickness must not vary more than $\frac{1}{32}$ in. (*b*) Width must be within $\frac{1}{32}$ in. of nominal size.

7. Character of leather must be uniform throughout the entire length of the belt.

8. One or more test pieces 1 in. wide will be cut at random lengthwise of the belt. Each test piece must show a tensile strength in pounds per inch of width not less than the following table. The vendor may furnish any thickness or weight of belting which will meet this requirement. Total elongation at the required load must not be less than 15 per cent or more than 20 per cent in 2 inches:

	Single			Double		
	Under 2 Inches	2 to 4 Inches	Over 4 Inches	Under 4 Inches	4 to 8 Inches	Over 8 Inches
Light	580	605	630	900	1000	1100
Medium	630	675	720	1100	1200	1300
Heavy	720	765	810	1300	1400	1500
Extra heavy	810	900	990	....	....	....

9. Cemented joints must not crack or yield before reaching a load equivalent to 90 per cent of the tensile strength specified in paragraph 8.



PLIABILITY TEST

10. A section 40 in. long and the full width of the belt will be tested for pliability by being suspended over a form of the dimensions shown, grain side down, and weighted at each end. Both ends must touch the bottom corners at a total weight per inch of width within the following limits:

	Minimum, Ounces	Maximum, Ounces
Light, single	8	15
Heavy, single	10	20
Light, double	45	60
Heavy, double	60	80

11. The total lubricating matter shall be increased by oil dressing to approximately 12 to 15 per cent by weight when examined in accordance with the practice of the American Leather Chemists' Association. Chemical examination shall not show loading for artificial weight, free mineral acid or anything detrimental to the strength, pliability or durability of the belt.

12. Belting must not run unevenly on the pulleys, show excessive stretch or develop other defects of material or workmanship in service, when properly applied.

For a complete discussion of the points covered by these specifications, reference should be made to the original article, but the following notes may call attention to the more important points. The numbers refer to the individual specifications.

Strength.—Center stock is the area of a prime steer hide extending from 15 to 18 in. on either side of the backbone and from the root of the tail about 48 in. toward the shoulder. Strength should be expressed in pounds per inch of width, instead of pounds per square inch (1, 5 and 8).

Pliability.—A stiff belt may be so badly burned by excessive slip when new as to shorten its life considerably. In order to transmit a given load, a stiff belt has to be tightened more than a pliable one, with the result that the increased bearing pressure consumes more power (10).

Artificial Finish.—For the sake of appearance, many manufacturers give their belts a high gloss finish which has a low coefficient of friction. Such a belt is liable to slip when new and become burnt in the process. For the same reason, manufacturers do not send out their product oil dressed unless so requested, although the dressing increases the life of the belt, as well as its resistance to moisture, fumes, mineral oil and other destructive agents (4 and 11).

Recent Chemical and Metallurgical Patents

Leaching Kiln Dust.—EVALD ANDERSON, of Los Angeles, Cal., finds that if a cement kiln is fired with pulverized coal, the ash-forming substances tend to combine with the volatilizing alkaline oxides, forming a compound which is slowly soluble in water. He therefore proposes to treat the resulting dust in a digester with water at high temperature and pressure, finding that in many cases it will raise the potash extraction up to 90 per cent within one hour's time. Lime, either from the kiln dust, or as an added reagent, is also thought to aid the solution of the valuable potash. (1,298,154; assigned to International Precipitation Co., March 25, 1919.)

Silver From Manganese Ores.—MARTINUS H. CARON, of Weltevreden, Java, patents an improvement of his former process covered in No. 1,232,216. In silver and gold ores bearing considerable quantities of MnO_2, it is well known that cyanide or amalgamation processes yield very poor extraction, possibly because of a compound between gold, silver and manganese. Caron proposes to break up these compounds, forming MnO and metallic silver or gold by a reducing roast at some temperature up to 1000 deg. C. which experience with that particular ore indicates, and then preventing reoxidation and recombination by cooling the calcine in producer gas or otherwise out of contact with oxygen. Thereafter cyaniding or amalgamation in the ordinary way will give good extractions. (1,298,454; assigned to Research Corporation of New York, March 25, 1919.)

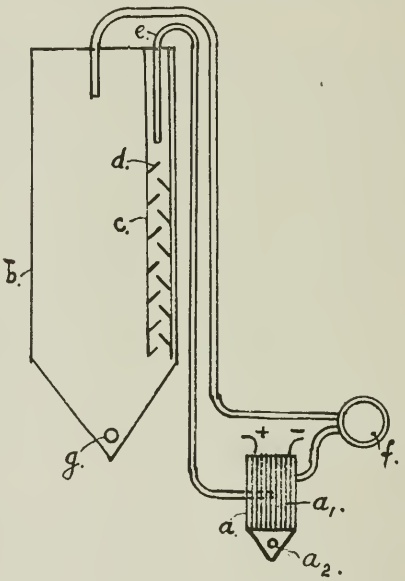
Steel Heat Treatment.—FEDERICO GIOLITTI, of Turin, Italy, patents an improvement in heating practice prior to quenching steel articles, in which he specifies that the metal be held at a point near that where diffusion of the constituents takes place with the greatest rapidity (i.e., at least 100 deg. C. above Ac_3) for a time depending upon the mass and shape of the piece. He then cools the furnace slowly to at least 30 deg. C. below the temperature necessary for effecting the ordinary homogeneous hardening (i.e., at least 50 deg. C. above Ar_3), holding the temperature constant for a somewhat shorter time, and then quenching the metal in a suitable medium. Following this, any correct tempering or annealing practice may be utilized to modify the resulting physical properties. Several practical examples are cited from experiments conducted to determine the best time and temperature limits. (1,296,649; assigned to Giov. Ansaldo & Co., Genoa, Italy, March 11, 1919.)

Metal Dust.—M. H. NEWELL, of San Francisco, Cal., proposes to make zinc dust by vaporizing spelter in a retort and condensing the vapor direct to solid without passing through the liquid phase. He notes, however, that if vapors come into contact with hot condenser walls, droplets of liquid metal form, which introduce large particles into the otherwise finely divided fume, and he proposes to prevent this contamination by a large cylindrical metallic condenser, connected to the retort mouth with a connecting hood, which may or may not be heat insulated. (1,295,573; assigned to The Alloys Co., Feb. 25, 1919.)

Australian Patents

Ore Flotation.—To preferentially separate lead sulphide (galena) from mixed sulphide ores by agitation, aëration froth flotation, a ferric salt such as ferric chloride or sulphate or sodium or potassium ferricyanide is added to the circuit water, preferably in the proportion of 5 lb. per ton of ore treated. (Australian Patent, No. 5714—1918. BROKEN HILL SOUTH SILVER MINING CO., T. A. Read, assignee.)

Recovering Gold and Silver.—To directly precipitate gold and silver from pulped ore without filtering, the pulp is agitated in a cyanide vat *b* by an air jet *g* and is drawn off to an electrolytic vat through a compartment *c* which is provided with perforated baffle plates *d* to separate the coarser particles. A syphon *e* conveys the pulp to an open precipitating vessel *a* having an air inlet pipe a_2 to maintain the



ore in suspension, and provided with depending electrodes a_1, through which low-tension current is passed. A pump *f* returns the pulp to the cyaniding vessel. The anodes are of iron containing 30 to 40 per cent silicon, and the cathodes consist of lead coated iron or mild steel plates, which are about 1 in. apart. (A. A. LOCKWOOD, Australian Patent No. 7097—1918.)

Treatment of Zinkiferous Ores.—To facilitate the formation of a pure zinc sulphate solution, the zinc is volatilized and dissolved in sulphuric acid. Impurities such as arsenic, antimony and cadmium are precipitated by barium sulphide, or calcium sulphide which is thrown down as insoluble sulphate. The ore is crushed, roasted, damped and mixed with carbon, and is fed to a furnace provided with a perforated grate to admit an air blast. The zinc, lead and other volatile constituents are here volatilized, and the resulting fumes collected in a baghouse. The residue is smelted, and any remaining lead and zinc are volatilized and collected in the main baghouse, the

non-volatile metal being recovered in a matte. The fume dust is now treated with sulphuric acid, lead sulphate settling to the bottom and the clear liquor being decanted and treated with barium sulphide. The zinc is finally deposited by electrolysis and sulphuric acid liberated, and used again. Zinc plates are used as cathodes, and gum arabic is added to insure an even deposition of zinc. (Australian Patent No. 6456—1918. J. H. and P. McP. GILLIES. Feb. 5, 1919.)

Sulphur From Roaster Gases.—ARTHUR B. FOSTER, of Washington, D. C., has discovered that if SO_2 gases from a mechanical roaster, working on ordinary sulphide ores, be passed through a granular mass of sulphides heated to from 750 to 900 deg. C., elemental sulphur is slowly produced, perhaps after the following equation:

$$2SO_2 + 3FeS = 5S + Fe_3O_4$$

If steam be added to the roaster gases, the hot sulphides may decompose it thus:

$$4H_2O + 3FeS = Fe_3O_4 + 3H_2S + H_2$$

Hydrogen sulphide then actively decomposes SO_2 by the well known reaction:

$$SO_2 + 2H_2S = 2H_2O + 3S$$

The inventor finds that if the granular ore be placed in a vertical retort, and the lower portion heated to a point just below sintering, moist roaster gases will rapidly and almost completely be broken up. Cold gas and sulphur fume will then be drawn from the top, and sent to a Feld washer or other suitable appliance for collecting the sulphur. Hot ore from the retort, partially desulphurized, forms the feed for the mechanical roaster. (1,296,585; assigned to Sulphur Syndicate, Ltd., of London, Eng., March 4, 1919.)

Personal

The American Red Cross asks our assistance in locating LIEUT. WILLIAM H. STUART, son of Duncan C. Stuart, of 12 Maple St., Oneonta, N. Y., and will appreciate any information that can be secured relative to his whereabouts. Lieut. Stuart is 27 years of age. He arrived from overseas service on Jan. 13 and went to Washington, where he was given his discharge. He returned to New York, and was last seen in that city Jan. 18 at 7:30 p.m. He is a graduate of Colgate, class of 1914, and took two years' post-graduate work at Brooklyn Polytechnic Institute. He is 5 ft. 8 in. tall, has dark hair and blue eyes and a ruddy complexion. He has a brown mole on the left side of his nose. He has three gold service chevrons on his sleeve, if in uniform. He was wearing, when last seen, spiral puttees and not the customary leather ones for officers. Information relative to him may be sent to D. C. Stuart, 12 Maple St., Oneonta, N. Y.

MR. J. P. BONARDI, assistant chemist, U. S. Bureau of Mines, who has been at the Seattle station experimenting on flotation problems with W. H. Coghill, has returned to his assignment at the Golden, Colo., station.

DR. JAMES E. CAMPBELL, president of the Dexter Sulphite Pulp & Paper Co., Dexter, N. Y., has returned from Europe, where he spent three months on a semi-official visit for the United States Government investigating the chemical, mechanical and labor conditions in the paper and pulp industry in France, England, Norway and Sweden.

MR. GORDON L. CAVE, formerly on an editorial detail with the pyrotechnic section, research division, Chemical Warfare Service, has accepted a similar position with the research department, Brown Co., Berlin, N. H.

MR. VERDON O. CUTTS, Sheffield, England, is visiting electrometallurgical centers in the Eastern and Central States.

MR. HERBERT FLECK has been appointed chief chemist, Crucible Steel Co., Pittsburgh, Pa., succeeding his brother, Mr. E. M. Fleck.

DR. WILLIAM MCPHERSON, who was recently discharged from the Chemical Warfare Service of the U. S. A., has returned to his former position at the Ohio State University, Columbus, Ohio.

MR. A. H. RICHARDS has been made superintendent of the copper smelter at Garfield, Utah. Before becoming assistant superintendent at Garfield for several years he held a like position at the A. S. & R. lead smelter at Murray, Utah.

MR. H. M. ST. JOHN has resigned his position as research engineer for the Commonwealth Edison Co. of Chicago to become assistant manager for the Detroit Electric Furnace Co.

MR. JOHN THOMPSON, chief engineer of the H. Koppers Co., will be in Europe for several weeks on a professional visit at various points in the Allied countries.

MR. FRANK J. TONE, past president of the American Electrochemical Society, has been made president of the Carborundum Co., Niagara Falls, succeeding the late Mr. Frank W. Haskell. MR. GEORGE R. RAYNER succeeds R. B. MELLON as vice-president and MR. F. H. MANLEY retains the office of treasurer.

MR. WALTER HARVEY WEED is consulting engineer for the Crystal Copper Co., which is operating the Goldsmith mine at Walkerville, Mont.

The following officers of the New York Section of the A. I. M. E. were elected May 7: E. P. MATHEWSON, chairman; R. M. ATWATER, JR., and WILLIAM YOUNG WESTERVELT, vice-chairmen; WILBER JUDSON, treasurer; E. S. BERRY and L. W. MAYER, executive committeemen.

At the annual meeting of the Chemists' Club held at Rumford Hall Wednesday, May 7, the following officers were elected: President, ELLWOOD HENDRICK; resident vice-president, WILLIAM F. HOFFMAN; non-resident vice-president, VICTOR F. BLOEDE, of Baltimore; secretary, J. R. MACPHERSON KLOTZ; treasurer, HENRY M. TOCH; trustees to serve three years, EDWARD WESTON and ALLEN ROGERS.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, May 10.

Aluminium:—The open market is nominal at 33c. Sheets 18 gage and heavier, 42c. Powder, 0.70-1.40 lb.

Copper:—The market continues to be quit with 15¾c. being the uniform price.

Copper sheets, hot-rolled	lb.	$0.22½—	.....
Copper sheets, cold rolled	lb.	.23½—	.....
Copper bottoms	lb.	.23½—	.....
Copper rods	lb.	.19½—	.....
Copper wire	lb.	.17½—	$0.18
High brass wire and sheets	lb.	.18½—	.....
High brass rods	lb.	.17½—	.....
Low brass wire and sheets	lb.	.18½—	.....
Low brass rods	lb.	.21½—	.....
Brazed brass tubing	lb.	.29½—	.....
Brazed bronze tubing	lb.	.33½—	.....
Seamless copper tubing	lb.	.28 —	.....
Seamless bronze tubing	lb.	.29½—	.....
Seamless brass tubing	lb.	.30 —	.....
Bronze (gold) powder	lb.	1.00 —	.....

Antimony:—No spot antimony is now available at 7c., though prompt shipments from the Orient can be obtained at this price.

Lead:—Market is inactive. East St. Louis quotes 4⅜c. and New York 4.5 to 5c. Sheet lead, 7⅜c.

Tin:—The price of 72½c. continues; however, when the price does change, it will be because the allotment has been consumed, and no previous notice is likely to be obtainable.

Zinc:—Spelter has gone down as low as 5.95c. during the past fortnight, and is now quoted at 6c. at East St. Louis. New York, 6.45c. Zinc dust, 9c. Sheets, 11c.

OTHER METALS

Bismuth	lb.	$3.20 — $3.65
Cadmium	lb.	1.40 — .....
Cobalt	lb.	2.50 — 3.50
Magnesium	lb.	1.75 — 2.10
Mercury	75 lb.	80.00 — .....
Nickel	lb.	.40 — .45
Tungsten	lb.	Nominal
Iridium	oz.	175.00 — .....
Palladium	oz.	120.00 — 121.00
Platinum	oz.	99.00 — 100.00
Silver	oz.	1.05½— .....

The Iron and Steel Market

The basic situation in the iron and steel market has not changed, but the atmosphere has been somewhat cleared by the final exit from the stage of the Industrial Board at Washington. The board had got into a hopeless tangle in its "controversy" with the Railroad Administration, desiring the latter to endorse prices for steel which the railroads considered too high, and to participate in a price maintenance movement which the Attorney General had declared in a formal opinion he considered illegal, a fact which the Industrial Board did not divulge, and only came out in a statement by its ex-chairman after he had resigned.

The resignation of the Industrial Board destroys any connection it may have been thought existed between Washington and the maintenance of steel prices. Nothing has occurred in the steel market as a result of the disappearance of the board. Now, as formerly, steel prices rest upon the general understanding of the steel producers individually that it is for their best interest to maintain existing prices, reduced from war-time prices as they have been by about $4 a net ton in December and $7 a net ton in March.

Steel Prices

If steel prices advance it will be because of a general buying movement starting on the present level. Never in the course of steel market history has a general buying movement, with advancing prices, started except after a break to abnormally low levels. Buyers have confidence in the market only when it is advancing. In all the market dips that have occurred little steel has been sold at the low point.

If steel prices decline it will be the result either of an accident, through one or more producers departing from the present understanding, or through the leaders in the trade reaching a judgment that the time has become ripe for starting a movement. The producers do not hesitate to cut prices if they feel certain that thereby they can set the market in motion. If they maintain present prices longer than necessary it will be through incorrect judgment due to their being less sanguine as to the future of business than they should be. If they allow the market to break before buyers are ready to take hold in a large way they will lose money through producing steel at less than cost, including overhead, when by maintaining prices they would have been able to make their overhead.

Operations

In April, according to the monthly report of the American Iron and Steel Institute, 2,239,711 gross tons of steel ingots were produced by 30 companies which in 1918 made 84.03 per cent of the country's entire output. From this it may be computed that the industry made steel in April at the rate of about 31,900,000 tons per annum, which was 65 per cent of capacity, taking capacity at 49,000,000 tons a year. This compares with 77 per cent in March, 85 per cent in February and 87 per cent in January. At the same rate of progression the operating capacity at the middle of May would be 53 per cent, while current trade estimates would place the rate at about 55 per cent.

There is a wide divergence in operating rates. The Steel Corporation is operating at a heavier rate than the independents as a whole, and in some cases it is doing so by operating some plants almost in full, with others entirely idle. In some branches, as the sheet and tin plate branches, the corporation is distributing work uniformly at each plant. Among the large independents the rate of operation is more commonly 40 or 45 per cent than a higher rate, while a few small interests are operating almost full, others being entirely idle. This divergence in operating rates makes price maintenance less easy than it was in 1908, when all producers operated at substantially the same rate.

Some Improvement

There has been improvement in the steel market in some respects, but increases in the volume of new bookings are usually more than offset by the exhaustion of old orders. Only two classes of consumers show full normal demand, these two being the automobile trade and the petroleum industry.

An important factor in the situation is the fact that steel making capacity has increased 40 per cent since 1914 and 100 per cent since 1907. On the one hand it would appear that a very large demand for steel would be necessary in order to give the industry a full operation at this time. On the other hand it is clear that if the greatly enlarged industry can operate even at 55 per cent when there appears to be scarcely any demand it would be no remarkable thing for a turn in affairs to bring about demand for the fullest output possible.

While the steel producers have such objections to an open market for their product that they can adhere to the existing schedule without any formal agreement to that effect, the merchant furnaces declared long ago that they regarded their market as an open one, and individual furnace interests frankly declare their willingness to cut prices if attractive orders are to be secured. Inquiries have been so small individually, however, that there has been but little price cutting. The furnaces do not specifically desire lower prices, but they desire information. They would like the market to show where it desires to go, and as promptly as possible, whereupon the furnaces individually can decide whether or not to blow out and await either lower costs or higher prices. Many have already done so. With relatively few exceptions the pig iron prices effective March 21 still obtain, while in steel the March 21 schedule is in full force, and well maintained.

The Chemical Market

New York, May 10.

Coal-Tar Products:—There has not been a great deal of change in this situation during the interim. The crudes continue to be moving in large quantities, and the situation in general is somewhat more encouraging than it was a few months ago. Benzol is moving in large volume, with contracts for quantities being closed right along. The other crudes also appear to be on a more stable basis, and the price situation, while unchanged in general, is firmer. It is not unlikely that higher prices will prevail when the large stocks held by the Government are disposed of. The intermediates, however, are sluggish and weak, with consumers confining their purchases to immediate requirements.

Benzol:—An unusually heavy volume of business is passing in this market. Several of the smaller plants are not operating, and while material is not scarce, it is not being offered as liberally as formerly. Prices are firm, though unchanged. Spot material is available only in limited quantities.

Phenol:—Some large sales have been closed of late, and though material is plentiful, the elimination of stray lots in the hands of weak holders has stimulated the market somewhat and prices are slightly higher.

Naphthalene:—While there is an improvement in the demand for spot and nearby material, there are but few large contracts being closed. Material is plentiful and prices are unchanged though slightly firmer.

Toluol:—There is a fair demand for moderate quantities of drum material, although there is but little business passing in tank-car lots. Buyers in most instances are closing only for current requirements. Prices are slightly firmer due to curtailment in production.

Cresol:—A steady volume of business is passing through regular channels, but there is no unusual activity. Prices are unchanged, and if anything are slightly easier.

Metol:—The domestic production of this material is now perfected to the state where a regular supply is possible.

There are moderate quantities of the foreign grade available, but prices are so much higher than those for domestic goods that the domestic is favored.

Alpha Naphthol:—There is an improvement in the volume of business passing, but there are large quantities of material available and prices are barely steady.

Aniline Oil:—The volume of business passing is not at all heavy; there is plenty of material available and prices are slightly easier.

Dimethylaniline:—The demand is confined to moderate and small quantities. The supply is ample with prices unchanged.

Diethylaniline:—Small quantities are passing hands, but the demand is not brisk and prices are unchanged.

Paranitraniline:—There are more concerns producing this material at present than formerly and contracts have been placed at low figures of late; spot prices, however, are practically unchanged.

Dinitrochlorbenzol:—An improvement is noted in the demand, but it is mostly confined to small quantities, with the supply ample; and prices unchanged.

Dinitronaphthaline:—Small lot trading appears to feature the market, the demand in the aggregate is not heavy and prices are not more than barely steady.

HEAVY CHEMICALS:—Trading continued during the past two weeks along the same moderate lines that has been evident for some time. It was asserted that many of the largest consumers are covered by existing contracts, while on the other hand where contracts have terminated, buyers in many instances are not disposed to enter new agreements over the year, but shop the market, and supplies are easy among second hands at prices materially lower than those of manufacturers. Therefore little interest is manifested by consumers in forward stocks and the entire situation, so far as heavy chemicals are concerned, still seems to be controlled by second hands. Export demand has not been very active, although there seems to be more life in trading in this direction, but the anticipated volume of orders that have been looked for has yet to appear in the market. The current movement for local consumption continues mostly of a routine nature and buyers retain a conservative policy.

Soda Ash:—The item has been very much neglected during the interval. Light ash sales were of a minor character with virtually no call for dense ash in any important quantities. Bags from the warehouse sold during the week at $1.50 for carload lots, but sales of this character were few and 5 and 10 ton lots were sold at $1.65 to $1.70 ex-warehouse. There has been little call for barrel material with isolated offerings noted from the warehouse at $1.60, which was an extremely low figure, while other resale lots were held at $1.70 to $1.75. Double bags were available during the week at 2c. Middle West, with material in the warehouse at San Francisco and Seattle being offered at $1.90 with no interested buyers.

Caustic Soda:—There was not much doing for this chemical, although some spasmodic activity was noted and sales were consummated through second hands as low as $2.50 for warehouse material, with 25 and 50 ton lots having sold during the week at $2.60 f.a.s. At the close some isolated offerings by weak holders were made at $2.50 ex-store, while in most instances $2.55 to $2.60 was asked for resale material. First hands were offering caustic soda at $2.80 f.a.s. early in the week, but toward the latter end were asking 3c. This advance seems to have affected the resale market, and despite the fact that offerings were liberal among second hands, there was no disposition to shade prices to stimulate business.

Bleaching Powder:—Producers continue to report a moderate inquiry for this commodity for export purposes and keen competition between second hands and producers alike has resulted in some lively bidding to close business. Some sales were consummated at low levels, by second hands, who still seem to be in a position to offer below manufacturers' figures. First hands were offering fresh material in export drums at $1.75 f.a.s., while domestic drums were quoted at $1.40 Niagara.

Bichromate of Soda:—Conditions in this market show no indication of any firming up in the situation, with sales for outside brands noted during the week at 8c. for spot material. Standard brands were offered by second hands at 9c. to 9¼c., while manufacturers were making an effort to keep the market up at 9½c.

Bichromate of Potash:—Although the present rate of absorbing stocks is having no effect on available supplies, producers report a slightly better movement for the product, particularly for export purposes, while local purchasing is apparently confined to immediate needs. In this instance the resale market offers material at 33¾c. ex-store or f.a.s., which is ¼c. lower than prices quoted by manufacturers.

Chlorate of Potash:—The recent lack of demand has had its effect in this market, with sales reported as low as 27c. for material for immediate shipment from the works, while spot material was offered at 29c., which was a decline of 4c.

Bicarbonate of Soda:—While there has been nothing in the way of any important trading passing for this commodity, there seems to be a sufficient call for the product to take the slack off the market. Stocks, however, are more than sufficient for the current call, but have not accumulated in any large surplus. Barrels at the works were offered at $2.30, while spot material was available at from $2.35 to $2.40. Kegs were quotably unchanged in price at $2.65 ex-warehouse.

Caustic Potash:—Reports of price cutting for the Western material has seemingly had no effect on the standard brand of this product, which is held firmly at 50c. for the 88-92 test, while sales of the other grades were noted as low as 40c. for the same test. Despite the variation of price, many consumers prefer the standard electrolytic product.

Chicago, May 10.

Although the connection between the Liberty Loan campaigns and the chemical market is hard to establish, it is a fact proved by previous experience that the drives have a tendency to slacken sales. The present drive for Victory Bond sales is no exception, the past two weeks showing but little activity in Chicago.

In general, conditions seem to be improving. Overstocks are gradually being used up, which is causing a gradual strengthening in the entire line of heavy chemicals. As was foreseen in the last report from this district, the bottom seems to have been reached and it is merely a question of time until all items which have been selling at less than cost of production will return to a reasonable quotation.

Caustic soda continues to be about the weakest item in the market, it still being possible to buy at an absurdly low figure, though it is showing some tendency to stiffen. Carbolic acid is still plentiful at less than cost, but it can no longer be had for the mere cost of containers. In the acids, sulphuric and muriatic have reached approximately their pre-war standing and should remain there. Ammonia and nitric acid are still slightly above the pre-war price, but seem to be inclined the same way.

Coal-tar products and their derivatives have taken an upturn, 90 per cent benzol bringing 25c. and being in fairly good demand. In this line the recently noted tendency of buyers to follow a hand-to-mouth policy is not so pronounced, the consumer who studies underlying conditions evidently being convinced that no lower prices are coming, but that, on the contrary, an increase may be definitely looked for.

Vegetable oils, particularly soap stocks, are in excellent demand, with prices firm and no reductions in sight.

Flotation Oils and Naval Stores:—Prices remain very firm with demand equal to if not in excess of supply. Steam distilled pine oil, 0.933 test pure, has registered an advance of 5c., now being sold at 75c. in barrel lots, 72c. in carloads. Lower test stuff is offered at from 4 to 6c. less. Hardwood creosote is unobtainable in this market, a bona fide purchaser last week being forced to go with his want unfilled. Turpentine continues scarce, there being sufficient to supply actual needs, however, at a firm market of 68c.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET MAY 12, 1919

Acetic anhydride	lb.	.55 —	.60
Acetone	lb.	.15½ —	.16
Acid, acetic, 28 per cent	cwt.	3.00 —	3.25
Acetic, 56 per cent	cwt.	6.00 —	7.00
Acetic, glacial, 99½ per cent, carboys	cwt.	12.00 —	14.00
Boric, crystals	lb.	.13½ —	.14½
Boric, powder	lb.	.13½ —	.14½
Hydrochloric, tech. 20 deg.	cwt.	1.50 —	3.00
Hydrofluoric, 52 deg.	lb.	.08 —	.08½
Lactic, 44 per cent. tech.	lb.	.12½ —	.13
Lactic, 22 per cent. tech.	lb.	.05½ —	.06
Molybdic, C. P.	lb.	6.50 —	7.40
Nitric, 40 deg.	lb.	.06 —	.07
Nitric, 42 deg.	lb.	.07 —	.08
Oxalic, crystals	lb.	.27 —	.30
Phosphoric, Ortho, 50 per cent. solution	lb.	.07½ —	.10
Picric	lb.	.50 —	.60
Pyrogallic, resublimed	lb.	2.55 —	2.70
Sulphuric, 60 deg., tank cars	ton	11.00 —	13.00
Sulphuric, 60 deg., drums	ton	17.00 —	.....

Sodium carbonate (sal soda)	100 lb.	1.60 —	2.00
Sodium chlorate	lb.	.15 —	.18
Sodium cyanide	lb.	.30 —	.31
Sodium fluoride	lb.	.14 —	.15
Sodium hydroxide, (caustic soda)	100 lb.	2.50 —	2.65
Sodium molybdate	lb.	2.50 —	.
Sodium nitrate	100 lb.	4.07½ —	...
Sodium nitrite	lb.	.13 —	.14
Sodium peroxide, powdered	lb.	.25 —	.30
Sodium phosphate, dibasic	lb.	.03½ —	.03½
Sodium potassium tartrate (Rochelle salts)	lb.	.43 —	.45½
Sodium prussiate, yellow	lb.	.16½ —	.22½
Sodium silicate, solution (40 deg.)	lb.	.02 —	.02½
Sodium silicate, solution, (60 deg.)	lb.	.03½ —	.04½
Sodium sulphate, crystals, (Glauber's salts)	cwt.	1.25 —	1.50
Sodium sulphide, crystal, 60-62 per cent, (conc)	lb.	.04½ —	.05
Sodium sulphite, crystals	lb.	.04 —	.06½
Strontium nitrate, crystals	lb.	.25 —	.30
Sulphur chloride	lb.	.07½ —	.09
Sulphur, crude	ton	35.00 —	37.50
Sulphur dioxide, liquid, cylinders	lb.	.10 —	.12
Sulphur, (sublimed), flowers	100 lb.	3.05 —	3.15
Sulphur, roll, (brimstone)	100 lb.	2.70 —	3.10
Tin bichloride, (stannous)	lb.	.22½ —	.25
Tin oxide	lb.	.63 —	.66
Zinc carbonate, precipitate	lb.	.18 —	.20
Zinc chloride, gran	lb.	.13½ —	.14
Zinc cyanide	lb.	.49 —	.50
Zinc dust	lb.	.12 —	.13
Zinc oxide, dry American	lb.	.09 —	.11½
Zinc sulphate	lb.	.03½ —	.04

Coal Tar Products—Intermediates, etc.

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	1.00 —	1.10
Alpha naphthol, refined	lb.	1.40 —	1.50
Alpha naphthylamine	lb.	.40 —	.50
Aniline oil, drums extra	lb.	.22 —	.24
Aniline salts	lb.	.28 —	.33
Anthracene, 80% in drums (100 lb.)	lb.	.90 —	1.00
Benzaldebyde (f.f.c.)	lb.	1.30 —	1.50
Benzidine, base	lb.	1.00 —	1.15
Benzidine, sulphate	lb.	.90 —	1.10
Benzoic acid, U. S. P.	lb.	1.00 —	1.25
Benzoate of soda, U. S. P.	lb.	1.00 —	1.25
Benzol, pure, water-white, in drums (100 lb.)	gal.	.22 —	.27
Benzol, 90%, in drums (100 lb.)	gal.	.22 —	.27
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate	lb.	5.50 —	6.00
Beta naphthol, sublimed	lb.	.60 —	.75
Beta naphthol, tech	lb.	.50 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U. S. P., in drums (100 lb.)	lb.	.18 —	.....
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	1.00 —	1.02
Cresylic acid, 95-97%, dark, in drums	gal.	.90 —	.92
Cresylic acid, 50%, first quality, drums	gal.	.60 —	.....
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	2.25 —	2.50
Dimethylaniline	lb.	.50 —	.57
Dinitrobenzol	lb.	.25 —	.35
Dinitrochlorbenzol	lb.	.25 —	.28
Dinitronaphthaline	lb.	.45 —	.55
Dinitrotoluol	lb.	.38 —	.45
Dinitrophenol	lb.	.30 —	.32
Dip oil, 25% tar acids, car lots, in drums	gal.	.38 —	.46
Dipbenylamine	lb.	.70 —	.75
H-acid	lb.	1.90 —	2.25
Metaphenylenediamine	lb.	1.80 —	..
Monochlorbenzol	lb.	.12 —	.14
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline, crushed in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.10½ —	.11½
Naphthionic acid, crude	lb.	1.00 —	1.25
Nitrobenzol	lb.	.13 —	.15
Nitro-naphthaline	lb.	.40 —	.45
Nitro-toluol	lb.	.17 —	.20
Ortho-amidophenol	lb.	6.00 —	....
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	1.25 —	....
Ortho-toluidine	lb.	.40 —	.45
Ortho-nitro-toluol	lb.	.35 —	.50
Para-amidophenol, base	lb.	2.75 —	3.50
Para-amidophenol, H. Cl.	lb.	3.00 —	3.25
Para-dichlor-benzol	lb.	.06 —	.10
Paranitraniline	lb.	1.10 —	1.25
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	3.00 —	3.25
Para toluidine	lb.	1.50 —	1.75
Phthalic anhydride	lb.	1.75 —	2.15
Phenol, U. S. P. drums (dest.), (240 lb.)	lb.	.08 —	.09
Pyridine	gal.	$2.50 —	.....
Resorcin, technical	lb.	3.50 —	3.75
Resorcin, pure	lb.	6.75 —	7.00
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.20 —	.30
Salicylic acid, U. S. P.	lb.	.25 —	.35
Salol	lb.	.75 —	.85
Solvent naphtha, water white, in drums, 100 gal.	gal.	.20 —	.25
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.18 —	.20
Sulphanilic acid, crude	lb.	.25 —	.30
Tolidine	lb.	2.25 —	2.50
Toluidine, mixed	lb.	.45 —	.80
Toluol, in tank cars	gal.	.22 —	.24
Toluol, in drums	gal.	.23 —	.30
Xylidine, drums, 100 gal	lb.	.40 —	.45
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal	gal.	.30 —	.40
Xylol, commercial, in tank cars	gal.	.30 —	.....

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	.36 —	.40
Beeswax, refined, yellow	lb.	.42 —	.47
Beeswax, white pure	lb.	.62 —	.65
Carnauba, No. 1	lb.	.80 —	.83
Carnauba, No. 2, regular	lb.	.65 —	.72
Carnauba, No. 2, North Country	lb.	.50 —	.55
Carnauba, No. 3, North Country	lb.	.42 —	.44
Ceresin, yellow	lb.	.16 —	.18
Ceresin, white	lb.	.18 —	.20
Japan	lb.	.15 —	.16
Paraffine wax, crude match wax (white) 105-110 m.p.	lb.	.07 —	.08
Paraffine waxes, crude scale, 117-119 m.p.	lb.	.07 —	.08
Paraffine waxes, crude scale, 124-126 m.p.	lb.	.07½ —	.08
Paraffine waxes, refined, 118-120 m.p.	lb.	.09 —	.09½
Paraffine waxes, refined, 123-125 m.p.	lb.	.09½ —	.10
Paraffine waxes, refined, 128-130 m.p.	lb.	.09½ —	.10½
Paraffine waxes, refined, 130-132 m.p.	lb.	.10½ —	.11
Paraffine waxes, refined, 133-135 m.p.	lb.	.11½ —	.12
Paraffine waxes, refined, 135-137 m.p.	lb.	.12½ —	.13
Stearic acid, single pressed	lb.	.17 —	.18
Stearic acid, double pressed	lb.	.18 —	.19
Stearic acid, triple pressed	lb.	.20 —	.22
Spermaceti	lb.	.30 —	.32

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lbs.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$0.68	
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.45	
Pine tar oil, ref., sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.,	gal.	.33	
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.	.58	
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.38	
Turpentine, crude, sp. gr., 0.900-0.970	gal.	.61	
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.24	
Hardwood oil, f.o.b. Mich., sp. gr., 1.06-1.08	gal.	.24	
Pinewood creosote, ref.	gal.	.48	

Naval Stores

The following prices are F.o.b., New York, for carload lots.

Rosin B-D, bbl	280 lb.	$12.20	—	$12.55
Rosin E-I	280 lb.	12.50	—	12.75
Rosin K-N	280 lb.	14.25	—	14.75
Rosin W. G.-W. W	280 lb.	15.25	—	15.60
Wood rosin, bbl	280 lb.	12.25	—	.....
Spirits of Turpentine	gal.	.78	—	.78½
Wood Turpentine, steam dist	gal.	.73½	—	.....
Wood Turpentine, dest. dist	gal.	.67½	—	.....
Pine tar pitch, bbls	200 lb.	8.00	—	8.25
Tar, kiln burned, bbl. (500 lbs.)	bbl.	12.50	—	13.50
Retort tar, bbl	280 lb.	13.50	—	14.50
Rosin oil, first run	gal.	.68	—	.78
Rosin oil, second run	gal.	.70	—	.80
Rosin oil, third run	gal.	.82	—	.83
Rosin oil, fourth run	gal.	.85	—	.95

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½	
70-72 deg., steel bbls. (85 lb.)	gal.	.31½	
68-70 deg., steel bbls. (85 lb.)	gal.	.30½	
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½	

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls	lb.	$0.21	—	$0.23
Castor oil, AA, in bbls	lb.	.24	—	.24½
China wood oil, in bbls	lb.	.17	—	.18½
Cocoanut oil, Ceylon grade, in bbls	lb.	.15	—	.15½
Cocoanut oil, Cochin grade, in bbls	lb.	.16½	—	.17
Corn oil, crude, in bbls	lb.	.18	—	.19
Cottonseed oil, crude (f.o.b. mill)	lb.	.17½	—	.....
Cottonseed oil, summer yellow	gal.	.22	—	.22½
Cottonseed oil, winter yellow	gal.	.23½	—	.....
Linseed oil, raw, car lots	gal.	1.56	—	1.58
Linseed oil, raw, tank cars	gal.	1.52	—	1.56
Linseed oil, boiled, car lots	gal.	1.58	—	1.60
Olive oil, commercial	gal.	2.10	—	2.25
Palm, Lagos	lb.	.15½	—	.18
Palm, bright red	lb.	.15	—	.16
Palm, Niger	lb.	.14	—	.15
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.18	—	.19½
Peanut oil, refined, in bbls	lb.	.22	—	.23
Rapeseed oil, refined, in bbls	gal.	1.50	—	1.55
Rapeseed oil, blown, in bbls	gal.	1.58	—	1.60
Soya bean oil (Manchurian), in bbls., N. Y.	lb.	.16	—	.16½
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.14¾	—	.15

FISH

Winter pressed Menhaden	gal.	$0.85	
Yellow bleached Menhaden	gal.	.87	
White bleached Menhaden	gal.	.89	
Blown Menhaden	gal.	.95	

Miscellaneous Materials

All Prices F.o.b., N. Y.

Barytes, domestic, white, floated	ton	$25.00	—	$36.00
Barytes, off color	ton	22.00	—	27.00
Blanc fixe, dry	lb.	.03½	—	.04½

Refractories

Following prices are f. o. b. works:

Chrome brick	net ton	90–100 at Chester, Penn.
Chrome cement	net ton	45–50 at Chester, Penn.
Clay brick, 1st quality fireclay	net ton	35–45 at Clearfield, Penn.
Clay brick, 2nd quality	net ton	30–35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50–55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in	net ton	80–90 at Chester, Penn.
Silica brick	net ton	41–45 at Mt. Union, Penn.

Ferro-alloys

All prices f. o. b. works.

Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.32	—	.40
Ferro-chrome, per lb. of Cr. contained, 2-4% carbon	lb.	.70	—	.....
Ferro-manganese, 70-80% Mn	gross ton	110.00	—	150.00
Spiegeleisen, 16-20% Mn	gross ton	40.00	—	50.00
Ferro-molybdenum, per lb. of Mo	lb.	2.50	—	3.00
Ferro-silicon, 50%	gross ton	90.00	—	115.00
Ferro-silicon, 75%	gross ton	150.00	—	175 00
Ferro-silicon, 10-15%	gross ton	50.00	—	60.00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	1.30	—	1.60
Ferro-ursnium, 35-50%, of U	lb.	7.00	—	.....
Ferro-vanadium, 30-40%, per lb. of contained V.	lb.	5.50	—	7.00

Reasles and overstocks make above prices approximate.

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.70		
Chrome ore, 48% and over	unit	1.00	—	$1.25
Coke, foundry, f.o.b. mines	net ton	4.50	—	5.00
Coke, furnace, f.o.b. mines	net ton	3.75	—	4.75
Petroleum coke, f.o.b. Atlantic seaboard	net ton	16.00	—	16.50
Fluorspar, gravel, f.o.b. mines	net ton	18.50	—	20.00
Manganese ore, 45% Mn and over	unit	.50	—	.85
Manganese ore, chemical (MnO_2)	gross ton	60.00	—	70.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75	—	.85
Tungsten, Scheelite, 60% WO_3 and over per unit of WO_3	unit	9.00	—	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50	—	8.00
Uranium oxide, 96%	lb.	.....	—	.....
Vanadium pentoxide, 99%	lb.	6.00	—	.....
Pyrites, foreign, lump	unit	.17	—	.....
Pyrites, foreign, fine	unit	.17	—	.....
Pyrites, domestic, fine	unit	.14	—	.....
Ilmenite, 50% TiO_2	net ton	30.00	—	.....
Rutile, 95% TiO_2	net ton	200.00	—	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	3.00	—	3.25

Reasles and overstocks make above prices approximate.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags	bbl.	$2.30
Lump lime, common, including container	300 bbl.	2.65
Common brick, at dock	M.	15.00
Hollow building tile, 8x12x12	M.	194.40
At factory, Perth Amboy, N. J., 12x12x12	M.	291.60
Yellow pine, 3x4 to 8x8, 20-24 ft. long	M.	39.00
Yellow pine, 3x4 to 8x8, 0-4 ft. long at Chicago	M.	38.50
Yellow pine, 3x4 to 8x8, 20-24 ft. long at St. Louis	M.	35.00
Roofings, tar felt (14 lb. per 100 sq.ft.)	ton	50.00
Roofings, tar pitch (in 400-lb. bbl.)	ton	19.00
Roofings, asphalt pitch	ton	30.00
Roofings, asphalt felt	ton	65.00
Roofings, slate-surfaced shingles, per roll of 108 sq.ft.		2.10
Roofings, slate-finished shingles, 100 sq.ft.		5.50
Linseed oil, raw in barrels	gal.	$1.63
Linseed oil, 5 gal. cans	gal.	1.76
Red lead, dry, 100 lb. keg	lb.	.13
Red lead, in oil, 100 lb. keg	lb.	.14½
Red lead, dry, 5 lb. cans	lb.	.15
Red lead, in oil, 5 lb. cans	lb.	.16½
White lead, dry and in oil, 100 lb. keg	lb.	.13
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	.13½
White lead, dry and in oil, 5 lb. cans	lb.	.15

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.66
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conchead for boilers, ½-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.35
Sheets, No. 10 blue annealed	100 lb.	3.55
Sheets, No. 28 galvanized	100 lb.	5.70

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

AJO—S. Clark plans to build a leaching plant having a daily capacity of 50 tons at Clarkston, near here. Estimated cost, $10,000.

DUNCAN—The Goldfield Consolidated Mining Co., Reno, Nev., plans to build a 100-ton mill and cyanide plant at Ash Peak, here. C. Storr, superintendent.

GLOBE—The Gila Monster Co. plans to build a 10-stamp mill and a cyanide plant. W. H. Seaman, superintendent.

MORENCI — The Phelps-Dodge Corp., Bisbee, plans to either remodel its old plant here or build a new modern plant. M. H. McLean, mine superintendent.

MORENCI—The Stargo Syndicate plans to build a mill and a 100-ton cyanide plant. M. J. Hannon, superintendent. J. M. Callow, Salt Lake City, Utah, consulting engineer.

TUCSON—The Mineral Hills Co. plans to build a concentrator. Estimated cost, $100,000. U. A. Fritschie, manager.

California

CULVER CITY—The H. Lehrman Studios have awarded the contract for the construction of a film manufacturing plant, to the Milwaukee Building Co., 316 Wright & Callender Bldg., Los Angeles. Estimated cost, $75,000.

MODESTO—The Modesto Gas Co. plans to build a 300,000-cu.ft. steel gas holder and extend the gas mains to new sections of the city, also to build a new gas generating unit and install two purifiers. Estimated cost, $65,000.

Colorado

BOULDER—The city plans to build a filtration plant. Estimated cost, $150,000. W. D. Salter, city engineer.

VANADIUM—The Primos Chemical Co. plans to build a treatment plant for the reduction and concentration of vanadium ores, and is in the market for lumber, metal work, crushing machinery, tanks, screens, motors, belting, etc. Estimated cost, $75,000.

Florida

WINTER GARDEN—The city plans an election June 15 to vote on $75,000 bonds for water, light and sewer improvements. Plans include the construction of a septic tank and disposal plant. W. H. Reams, mayor.

Georgia

LA GRANGE—G. H. Sargent, city engineer, will soon receivs bids for the construction of a sewage disposal plant. C. L. Smith, clerk and treasurer.

Idaho

NAMPA—The city plans to extend the sewerage system and build a septic tank. Estimated cost, $80,000.

Illinois

CHICAGO—Foley & Co., 2835 Sheffield Ave., manufacturer of proprietary medicines, plans to build a 2-story addition to its existing plant, also a new 5-story, 40 x 125-ft. building. Estiamted cost, $200,000. E. R. Krause, Majestic Theater Bldg., architect.

CHICAGO—The Municipal Tuberculosis Sanitarium, Crawford and Bryn Mawr Aves., has awarded the contract for the construction of a 2-story, 57 x 123-ft. laboratory, to H. F. Friestedt Co., 327 La Salle St. Estimated cost, $75,000. Noted Mar. 15.

JACKSONVILLE—The city voted $75,000 bonds for the construction of a dam and filtration plant. E. M. Henderson, city engineer.

MADISON—The Barber Asphalt Co., Land Title Bldg., Philadelphia, Pa., plans to build a refinery here. A. L. Robinson, c/o owner, chief engineer.

WHEATON—The State Board of Health, Springfield, has approved plans for the construction of a sewage disposal plant. L. Ruddock, city engineer.

Indiana

INDIANAPOLIS—The Hook Drug Co. has awarded the contract for the construction of a 3-story building on Market and Noble Sts., to R. Baumann. Estimated cost, $18,000. Plans include the installation of laboratories, etc.

NEW ALBANY—The Calumet Fertilizer Co. plans to build an acidulating plant for the treatment of commercial fertilizers. Estimated cost, $100,000. O. Voyles, manager.

Iowa

COUNCIL BLUFFS — The city has awarded the contract for the construction of a garbage incinerator, to the Jones Garbage Crematory Co., St. Louis, Mo. Estimated cost, $16,200. C. O. Frazer, city clerk.

FAIRPORT—The Commissioner of Fisheries, Department of Commerce, Washington, D. C., will receive bids until May 26 for the construction of a laboratory building at the Biological Station, here.

WILLIAMSBURG—The city has awarded the contract for the construction of a disposal plant to Ward & Weighton, 516-517 Davidson Bldg., Sioux City. Estimated cost, $12,500. E. Lewis, city clerk.

Kansas

TOPEKA—W. L. Johnson, c/o the Wolff Packing Co., foot of Quincy St., plans to build a 1-story, 44 x 54-ft. serum plant and a 1-story, 50 x 96-ft. hog shed on Jefferson and Crane Sts. Estimated cost, $15,000. C. D. Cuthbert, 736 Kansas Ave., architect.

TREECE—The Wachusetts Mining Co., Commeree, Okla., plans to install a hand jig plant and is in the market for several hand jigs. A. Mayerhoff, manager.

Kentucky

ASHLAND—The city is having plans prepared by Alvord & Burdick, engineers, 8 South Dearborn St., Chicago, Ill., for the construction of a filtration plant having a capacity of 2,000,000 gallons. E. C. Means is chairman of the water commissioners.

LOUISVILLE—The Louisville Cotton Seed Oil Co., 1318 McHenry St., plans to rebuild its plant recently destroyed by fire, entailing a loss of $500,000.

Maryland

BALTIMORE—The State Department of Health will alter the bacteriological laboratory at 14 West Saratoga St. Address R. B. Morse, on premises.

BALTIMORE—The H. S. Wampole Co., 761 Columbus Ave., received bids for building an addition to its proprietary medicine plant on Barre and St. Peter Sts., from the B. F. Bennett Building Co., 123 South Howard St.; G. W. Tovell, Eutaw and McCullough Sts.; Rhodes & Billops, 611 Haywood St., Arlington. Estimated cost, $35,000.

HAGERSTOWN—Shaffer & Locke, 684 Pennsylvania Ave., plan to install an acetylene welding plant for aluminium, brass, copper, etc.

HANCOCK—The Maryland Glass Sand Co., Hagerstown, is building a plant at Round Top, near here, to have a yearly capacity of 60,000 tons. Estimated cost, $50,000. E. W. Funkhouse, secretary.

HIGHLANDTOWN (Baltimore P. O.)—Jones & Lamb Co., Pennsylvania and Fulton Aves., Baltimore, plans to convert the plant of the Monumental Brewery Co., on Lombard St., into a meat packing plant and oil refinery; also construct several new buildings. Estimated cost, $500,000. C. B. Comstock, 110 West 40th St., New York City, engineer.

HOMEWOOD (Baltimore P. O.)—The trustees of Johns Hopkins University received bids for the construction of a 1-story, 50 x 150-ft. laboratory, from the Consolidated Engineering Co., 243 Calvert Bldg., B. F. Bennett Building Co., 123 South Howard St.; Frainie Bros. & Haigley, 18 Clay St. Estimated cost, $50,000. Equipment for electro-chemistry and metallurgical chemistry laboratories, also for physical, organic and inorganic chemistry study and experimentation will be installed in same. F. J. Goodnow, president.

Massachusetts

CHATHAM—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of a septic tank and sewage disposal plant, here, to H. S. Roberts, 1123 Broadway, New York City, N. Y. Estimated cost, $40,925 (75 days). Noted April 1.

WILLIMANSETT — The Papermakers' Chemical Co., Main St., Holyoke, plans to build a plant for the manufacture of chemicals necessary to the paper trade and principally for purification of rosins, on Chicopee St., here. Estimated cost, $75,000. R. M. Snell, manager.

Missouri

CAMERON—The city is having plans prepared for the installation of a filtration plant at the waterworks.

ST. LOUIS—The National Barium & Chemical Co., 7338 Arlington Ave., plans to build a chemical plant near Union St. and Natural Bridge Rd. Estimated cost, $50,000. O. Virden, president.

ST. LOUIS—The Parker-Russell Mining & Mfg. Co., Laclede Gas Bldg., plans to rebuild its silica factory at 3200 Morganford Rd., recently destroyed by fire entailing a loss of $20,000. L. Parker, c/o owner, engineer.

Montana

BUTTE—The Trustees of the State School of Mines plan to build a chemical and metallurgical building. Estimated cost, $100,000.

HARDIN—The Board of Education has awarded the contract for the construction of a 3-story high school on 5th St. to the Veatch Co., Billings. Laboratory fixtures and furnishings will be installed in same. Total estimated cost, $53,000.

New Jersey

JERSEY CITY—The city has awarded the contract for building an additional wing at the City Hospital, to W. H. & T. W. Cane, Baldwin Ave. Plans include the installation of a laboratory and fumigation building. Estimated cost, $963,145.

New York

ATHENA—The town is having plans prepared by M. Vrooman, consulting engineer, Gloversville, for the construction of a water system, water filters and a pumping station, also a sewage system and a complete disposal plant.

BROOKLYN—J. Bene & Sons, 641 Dean St., have awarded the contract for the construction of a 2-story, 100 x 100-ft. chemical factory on Carlton St., to the W. Kennedy Construction Co., 215 Montague St. Noted April 1.

BROOKLYN — The Brooklyn Hebrew Home & Hospital for the Aged, Howard and Dumont Ave., plans to build a 4-story, 90 x 100-ft. addition to its home and hospital. A chemical laboratory will be installed in same. Total estimated cost, $100,000. L. Abramson, 220 5th Ave., New York City, architect.

BROOKLYN — The Maternity Hospital Society, 1666 Pitkin Ave., plans to build a 3-story, 50 x 80-ft. hospital on Howard and Dumont Aves. Project includes the installation of a chemical laboratory. Estimated cost, $75,000. Cohn Bros., 361 Stone Ave., architects.

BUFFALO—The Mentholatum Co., 146 Seneca St., has awarded the contract for the construction of a 4-story, 80 x 100-ft. factory to the J. W. Cowper Co., Fidelity Bldg. Estimated cost, $225,000. Noted April 25.

BUFFALO—The U. S. Rubber Reclaiming Co., 784 Babcock St., has awarded the contract for the construction of a 1-story 80 x 150-ft. addition to its factory, to B. I. Crooker, Builders' Exchange. Estimated cost, $10,000.

CARTHAGE—J. Thompson, Carthage, has purchased the property between North Washington and North Clinton Sts., and plans to install sewer service to all lots

on tract, also construct a sewage disposal plant. Estimated cost, $13,500.

LONG ISLAND CITY—The General Chemical Co., 25 Broad St., New York City, has awarded the contract for the construction of a laboratory building on Washington Ave. and Halle St., here, to Leddy & Moore, 105 West 40th St., New York City. Estimated cost, $35,000.

LONG ISLAND CITY—The Liquid Carbonic Co., 624 1st Ave., New York City, has awarded the contract for the construction of a 1-story, 65 x 155-ft. factory and warehouse on Maspeth Ave., between Metropolitan and Grand Aves., to the G. A. Engineering Co., 239 Vernon Ave., Brooklyn. Estimated cost, $35,000.

NEW YORK—G. J. Adams, consulting engineer, 39 South St., is in the market for a Karl Kiefer filter with 22 cells.

NIAGARA FALLS—The Defiance Paper Co., Walnut and 3rd Sts., has awarded the contract for the construction of an addition to its pulp mill on Walnut St. to the J. W. Cowper Co., Fidelity Building, Buffalo. Estimated cost, $25,000. Noted April 15.

ROCHESTER—The city is having plans prepared for the construction of a sewage disposal plant in the 23rd Ward, to include one Imhoff tank and pumping system to care for the territory between Lata Road and Beach Ave.; also one in the Maplewood District, to include sprinkler filters. Address J. F. Skinner, assistant city engineer.

SYRACUSE—The city plans to build a garbage disposal plant. H. C. Allen, city engineer.

WAUSAU—The Chamberlain Paint & Oil Co. plans to build an addition to its present plant and install additional paint grinding and manufacturing machinery.

North Carolina

HIGH POINT—The city has awarded the contract for installing filtering apparatus and filters at the proposed water plant, to R. K. Stewart & Son, Farmville, Va., at $59,930, and the Pittsburg Meter Co., First National Bank Bldg., Pittsburgh, Pa., at $21,400.

Ohio

CLEVELAND—The Foster Manufacturing Co., 2113 East 79th St., has awarded the contract for the construction of a 1-story, 51 x 85-ft. sheet metal factory at 7600 Carnegie Ave., to I. Brygnons, 3505 Woodland Ave. Estimated cost, $6000.

CLEVELAND — The Ko-Ko-Mar Co., Leader-News Bldg., plans to remodel the brewery on West 46th St. and Train Ave. into a food products plant. Estimated cost, $40,000. A. C. Bishop, 427 Guardian Bldg., architect.

DOVER—The Tuscarora Rubber Co., c/o the W. C. Owen Engineering Co., engineers, 1900 Euclid Bldg., Cleveland, plans to build a 3-story rubber factory here.

Oklahoma

DOUTHAT—The Admiralty Zinc Co. plans to install a new sand jig and is in the market for one set of jig irons and one set of chat rolls. W. B. Shackelford, general manager.

DOUTHAT—W. Dudley plans to build a tailing mill to handle sand tailings from Admiralty Mill No. 2 and is in the market for six tables, motor, set rolls and belting.

DUNCAN—The city has awarded the contract for the construction of a sewage disposal plant to L. H. Haas. Estimated cost, $7556.

HENRYETTA—The city voted $310,000 bonds for waterworks improvements, to include the construction of a filtration plant, settling basins, supply line and distribution system. H. M. La Rue, superintendent of water works. Burns & McDonnell, Interstate Bldg., Kansas City, Mo., engineers.

HOCKERVILLE—The Prospectors Mining Co. plans to move its mill from Aurora field and erect same at Hockerville, and is in the market for an engine, boiler, rock drills and tables. W. Crawford, superintendent.

Pennsylvania

PHILADELPHIA—The Liquid Carbonic Co., 3100 South Kedzie Ave., Chicago, Ill., plans to build a 2-story, 60 x 108-ft. factory here. J. J. Novy, 3223 West 22nd St., Chicago, Ill., architect.

South Carolina

COLUMBIA—The Carolina Veneer Co., Tobacco St., plans to rebuild its plant recently destroyed by fire. J. E. Kocha, president and treasurer.

Texas

DALLAS—The Bell & Blake Co., 118 Field St., plans to install two 20-ton Scott furnaces for recovering quicksilver from Cinnabar ores.

LONGVIEW—The Texas Leasing & Development Co., Wichita Falls, plans to build an oil refinery having a daily capacity of 10,000 bbl.

WACO—The Arrow Refining Co., Suite 2010 Amicable Bldg., plans to build an oil refinery having a capacity of 5000 bbl. Estimated cost, $300,000. C. S. Dawley, president.

WICHITA FALLS—The Meridian Gasoline Co., organized by J. F. Darby, 408 New Daniels Bldg., and W. K. Campbell, 1644 South Denver St., both of Tulsa, Okla., and others, plan to build a casing-head gasoline plant here. Estimated cost, $200,000.

WICHITA FALLS—The Texhoma Oil & Refining Co. has acquired the oil refinery of Fisher & Gilliland, and plans to increase the daily capacity of same from 1200 to 2000 bbl.

Virginia

NORFOLK—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of galvanizing plant here to the W. Linker Co., 831 Cherry St., Philadelphia, Pa. Estimated cost, $119,000. Noted April 15.

West Virginia

CHARLESTON—J. S. Lakin, of the State Board of Control, will receive bids until May 22 for the construction of a sewage-sedimentation tank, sprinkling filter, sludge bed and chlorinating plant. C. E. Collins, Drexel Bldg., Philadelphia, Pa., consulting engineer.

CLARKSBURG—The Lafayette Glass Co. plans to rebuild its plant recently destroyed by fire, entailing a loss of $300,000.

WHEELING—The city plans an election soon to vote on a bond issue for the construction of a filtration plant, to be series of mechanical rapid rate pumps. Chester & Fleming, Union Bank Bldg., Pittsburgh, Pa., engineers.

British Columbia

ANYOX—The Granby Consolidated Ore Co. plans to build a plant. Estimated cost, $50,000.

VICTORIA—The Department of Mines plans the construction of a building for mineralogical experiments. Estimated cost, $200,000.

Ontario

LARDER LAKE—The Associated Gold Fields of Larder Lake plan to build a mill and are in the market for machinery for the mill and cyanide plant, motors, etc. Estimated cost, $600,000. A. Diampre, superintendent.

Coming Meetings and Events

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its Summer meeting at Boston, Mass., June 18-21. A symposium is planned on electric furnaces.

THE AMERICAN IRON & STEEL INSTITUTE will hold its next meeting on May 23-24 at the Hotel Pennsylvania, New York.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 22nd annual meeting at Atlantic City, N. J., June 24-27. The headquarters will be at the Hotel Traymore.

THE AMERICAN ZINC INSTITUTE will hold its annual meeting at St. Louis, Mo., June 9-10.

THE FRANKLIN INSTITUTE will hold a meeting on May 21 at which the presentation of the Franklin Medal to Major-General James Douglas McLachlan on behalf of his Britannic Majesty's Government for Sir James Dewar will be given, together with the presentation of the Franklin Medal to Major-General George Owen Squier of the United States Army.

THE NATIONAL FERTILIZER ASSOCIATION will hold its 26th annual convention the week of June 23 at the Hotel Griswold, Eastern Point, New London, Conn.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its Spring meeting, June 11-14 inclusive.

Industrial Notes

THE CHEMICAL FOUNDATION, INC., which was organized at the suggestion of the Alien Property Custodian for the purpose of purchasing and exploiting chemical patents and trade marks previously owned by Teutonic interests in this country, has leased the entire fourth floor from the Irving Trust Co. at 81-83 Fulton St., for a long term of years. The new headquarters of the Foundation will be made a center for research for the advancement of chemistry and its allied sciences and their application to manufacturing purposes in the United States.

KARL S. REINHARDT announces the removal of his office from 1210 Yeon Bldg. to the Worcester Bldg., Portland, Ore.

THE HOHMANN-NELSON CO. has been organized at Eau Claire, Wis., for the manufacture of temperature, pressure, time and level controllers and recording thermometers and gages for industrial processes. The officers of the company are A. B. Hohmann, president, A. J. Nelson, vice-president and secretary, and Edward Hutchens, treasurer.

THE STEPHENS-ADAMSON MFG. CO., Aurora, Ill., has appointed Fred W. Wells as assistant engineer of the New York district office. Mr. Wells was associated with this company prior to his entering the service early in the year 1918. He was appointed first lieutenant in the 26th Engineers, served in various sections of France and with the first army during the Argonne-Meuse operation.

THE TALC PRODUCTS CO., INC., has been formed by a group of Los Angeles men with offices in the Washington Bldg., Los Angeles, Cal., to engage in the manufacture of metal-workers' crayons from white rock talc. Mr. H. N. Thomson is president of the company.

THE BROWN CO., Portland, Me., has been granted a writ of certiorari by the U. S. Supreme Court in the so-called hydrogenated oil case. This litigation, which is to determine the scope or validity of the Burchenal patent, owned by Procter & Gamble, has so far resulted in a decision for the defendant in the District Court and a reversal in the Appellate Division. The Supreme Court will now pass upon the question, which is said to be the first patent case of the kind to come before them.

THE AMERICAN STEAM CONVEYOR CORP., Chicago, Ill., announces the appointment of Mr. N. B. Stewart as district representative in charge of its St. Louis territory. Offices have been opened at 708 Merchants-LaClede Bldg., St. Louis, Mo.

THE COMMERCIAL ELECTROLYTIC CORP., New York City, announces the removal of offices from 55 Liberty St. to 527 Fifth Avenue.

THE TECHNICAL PRODUCTS CO., INC., and the HERCULES ENGINEERING CORP., of 501 Fifth Ave., New York, announce the appointment of Mr. A. B. Curtis, Jr., as Western manager with headquarters at 728 Monadnock Bldg., Chicago, Ill.

THE NEW JERSEY ZINC CO. announces the appointment of Mr. E. V. Peters to succeed Mr. H. C. Clopper as head of the sales department.

THE LUNKENHEIMER CO. announces that after May 1, 1919, the New York branch will be located at 129-135 Lafayette St.

THE NATIONAL BANK OF COMMERCE IN NEW YORK has opened an office in London, at 17 Sherborne Lane, King William St. Mr. Kenneth H. Rockey is in charge.

THE AMERICAN ZINC, LEAD & SMELTING CO., with offices in St. Louis, New York and Boston, has arranged with the American Zinc Sales Co. to handle the Azo zinc oxide in Chicago and adjacent territory. The latter company has offices at 1415 Conway Bldg. under the management of Mr. A. C. Eide. Mr. Eide previously had an active part in the technical development of processes for the manufacture of zinc oxide.

THE JOSEPH DIXON CRUCIBLE CO., Jersey City, N. J., held a meeting on April 21 at which the following officers were elected: President, George T. Smith; vice-president, J. H. Schermerhorn; secretary, Harry Dailey; treasurer, William Koester; assistant secretary and assistant treasurer, Albert Norris. Announcement is made of the removal of the Philadelphia sales office of the company from 1020 Arch St. to Rooms 801-802, Finance Bldg. This office is under the direction of Mr. W. G. Stringer.

THE CELITE PRODUCTS CO. announces the appointment of Mr. Frank Bethune, 808 Perdido St., New Orleans, La., as repre-

sentative for the Louisiana and Mississippi district. A warehouse stock will be carried to insure prompt deliveries of Sil-O-Cel ick, powder and cement for insulation, also Fiber-Cel for filtration. Mr. Ward D. Dygert has been appointed Detroit representative with headquarters in the Book Bldg.

THE FRENCH & AMERICAN BANKING CORP., representing an alliance of French and American banking interests with combined resources of over one and a quarter billion dollars, has been incorporated to promote trade between France and the United States. The incorporators are James S. Alexander, president of the First National Bank of Boston; Maurice Silvester, American representative of the Comptoir National d'Escompte de Paris, and others. Mr. Silvester will be president of the new company. There will be twelve directors, six to represent the American group and six the French group.

THE AMERICAN CHAMBER OF COMMERCE IN LONDON announces the appointment of Mr. George P. Toby as executive secretary. Mr. Toby spent over a year in Washington on plans for co-operation between the various Government departments and the business world. His work as investment banker has also given him knowledge of commercial possibilities that will be of value to American manufacturers who desire to engage in export trade. It is desired that the American manufacturers, merchants and exporters should learn to look upon the American Chamber of Commerce in London as an overseas service bureau to promote American business.

THE WILKENS & ANDERSON CO. announces the new location of general offices at 213-215 Desplaines St., Chicago, Ill.

New Publications

DESIGN OF CONCRETE MIXTURES. By Duff A. Abrams. Published by the Structural Materials Research Laboratory, Lewis Institute, Chicago, Ill.

TUNGSTEN, CINNABAR, MANGANESE, MOLYBDENUM, AND TIN DEPOSITS OF IDAHO. By D. C. Livingston, with notes on the antimony deposits, by Francis A. Thomson. University of Idaho, School of Mines Bull. No. 2, Vol. XIV.

ANALYSIS AND TESTS OF RIGIDLY CONNECTED REINFORCED CONCRETE FRAMES. By Mikishi Abe. Bull. No. 107, Engineering Experiment Station; The College of Engineering and Engineering Experiment Station, a pictorial description; A Discussion of the Development and Needs of the College of Engineering and the Engineering Experiment Station of the University of Illinois, Vol. XVI, No. 12. The above are published by the University of Illinois, Urbana, Ill.

A SUMMARY OF MINING IN THE STATE OF WASHINGTON. By Arthur Homes Fischer, Engineering Experiment Station Series, Bull. No. 4, published by the University of Washington, Seattle, Wash.

BIENNIAL REPORT OF THE STATE GEOLOGIST, 1917-1918. Published by the North Carolina Geological and Economic Survey, Raleigh, N. C.

COMMERCE MONTHLY is the title of a booklet on commerce and finance, the initial issue of which has just been published by the National Bank of Commerce in New York. The purpose of the magazine is "to serve as a medium through which the experience and investigations that have proved useful to this bank in the fields of industry, commerce and finance may be shared with its friends." It is announced that the table of wholesale commodities prices, the money market and the market letter will be regular features of the publication.

NEW BUREAU OF STANDARDS PUBLICATIONS: Circ. 24, entitled "Publications of the Bureau of Standards," 5th edition, issued April 14, 1919. This circular gives titles of all four series—scientific papers, technologic papers, circulars and miscellaneous publications. The list is numerically arranged in each series and each title is accompanied by an abstract. A full index facilitates reference to publications on specific subjects; Circ. No. 77, Table of Unit Displacement of Commodities. Issued Mar. 10, 1919; Circ. No. 79, Electrical Characteristics and Testing of Dry Cells, issued April 25, 1919; Special Agent Series No. 175 is on Construction Materials and Machinery in South American Countries. The pamphlet has been prepared to give information regarding the requirement for all kinds of construction material and machinery in Chile, Peru and Ecuador. Copies are obtainable from the Supt. of Documents, Government Printing Office, Washington, D. C., at 20c. each.

THE U. S. DEPARTMENT OF LABOR, U. S. TRAINING SERVICE. Bull. No. 7 on Industrial Training and Foreign Trade; Bull. No. 6, Labor Turnover and Industrial Training.

THE FEDERAL BOARD FOR VOCATIONAL EDUCATION has issued a series of Opportunity Monographs. Series No. 23, Commercial Occupations; Series No. 25, Occupations in the Electrical Manufacturing Industries; Series No. 22, Teaching as a Vocation; Series No. 21, Farm Management as a Vocation; Series No. 29, Occupations in the Automobile Manufacturing Industry; Series No. 19, The Lumber Industry and No. 18, Journalism as a Vocation.

NEW UNITED STATES GEOLOGICAL SURVEY PUBLICATIONS: I:18, Gold, Silver, Copper, Lead and Zinc in Idaho and Washington in 1917, Mines Report. By C. N. Gerry (Mineral Resources, 1917, Part 1), published April 3, 1919; I:19, Gold, Silver, Copper, Lead and Zinc in Arizona in 1917, Mines Report. By V. C. Heikes (Mineral Resources, 1917, Part I), published April 1, 1919; I:17, Quicksilver in 1917. By F. L. Ransome, with a Bibliography. By I. P. Evans (Mineral Resources, 1917, Part 1), published March 18, 1919; II:27, Mineral Water in 1917. By Arthur J. Ellis (Mineral Resources, 1917, Part II), published April 21, 1919; I:20, Iron Ore, Pig Iron and Steel in 1917. By Ernest F. Burchard (Mineral Resources, 1917, Part I), published April 2, 1919; II:1, Fuel Briquetting in 1918. By C. E. Lesher (Mineral Resources, 1918, Part II), published April 30, 1919.

NEW U. S. TARIFF COMMISSION PUBLICATIONS: Japan—Trade During the War and Costs of Production in the Sugar Industry.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 166, A Preliminary Report on the Mining Districts of Idaho. By Thomas Varley, Clarence A. Wright, Edgar K. Soper and Douglas C. Livingston; Bull. 169, Illinois Mining Statutes Annotated. By J. W. Thompson, including Illinois Mining Laws; Tech. Paper 178, Notes on Lignite, its Characteristics and Utilization. By S. M. Darling; Tech. Paper 207, Combustion Experiments with North Dakota Lignite. By Henry Greisinger, C. E. Augustine and W. C. Harpster; Tech. Paper 209, Traps for Saving Gas at Oil Wells. By W. R. Hamilton; Tech. Paper 213, Quarry Accidents in the United States During the Calendar Year 1917. Compiled by Albert H. Fay; Tech. Paper 218, Boiler Water Treatment. Reprint of Engineering Bull. No. 3, prepared by the U. S. Fuel Administration in collaboration with the Bureau of Mines; Tech. Paper 219, Combustion and Flue Gas Analysis. Reprint of Engineering Bull. No. 4, prepared by the U. S. Fuel Administration.

Manufacturers' Catalogs

THE FOAMITE FIREFOAM CO., New York City, has issued a catalog entitled "60 Seconds—And Out!" which illustrates and describes the use of Foamite Firefoam for putting out fires at oil plants, garages, etc.

THE WILL CORPORATION, Rochester, N. Y., has published a complete catalog of laboratory glassware, representative lines of porcelain ware and the fused silica product known as vitreosil.

THE AMERICAN STEAM CONVEYOR CORP., Chicago, Ill., has published a booklet on the ash-handling problem, describing a steam jet ash conveyor.

THE TAYLOR INSTRUMENT COMPANIES, Rochester, N. Y., call attention to a general industrial catalog of Tycos instruments which is now ready for distribution. This new publication describes the whole line of Tycos instruments for the indicating, recording and control of temperature.

THE ELECTRIC FURNACE CO., Alliance, Ohio, has just received from the press Booklet 5B on Baily electric furnaces for melting brass. This 24-page booklet illustrates and describes a few typical installations and also attempts to answer questions that relate to fuel cost, reliability of essential furnace parts, foundry conditions, quality of metal produced and comparative metal losses.

THE VULCAN SOOT CLEANER CO., Du Bois, Pa., announces a new leaflet on Vulcan soot cleaners for return tubular boilers, which describes model "M," front end type, and model "Rb," rear end type. It shows how the cleaner is installed in settings of typical construction and gives the results of tests conducted by the engineering department of the University of Illinois, and by the Iowa Soldiers' Home at Marshalltown, Iowa.

THE MORSE CHAIN CO., Ithaca, N. Y., has issued a booklet on chain drives which is an illustrated article reprinted from the National Association of Cotton Manufacturers' 1919 Year Book.

THE MAGNETIC MANUFACTURING CO., Milwaukee, Wis., calls attention to Bull. L, on its type "L" magnetic separator.

THE PORTABLE MACHINERY CO., INC., Passaic, N. J., calls attention to a folder replete with illustrations showing the various uses of the scoop conveyor, describes the labor, time and money saving features of the machine in storing, reclaiming, loading and unloading material such as coal, coke, ashes, sand, gravel, crushed stone, fertilizer, cement, chemicals, etc. Copies will gladly be sent upon request.

A Penalty on Western Residence

ANNOUNCEMENT is made elsewhere in this issue of the increased postage that must be charged to Western subscribers of CHEMICAL & METALLURGICAL ENGINEERING beginning July 1, 1919. This extra charge is the consequence of an act of Congress which practically penalizes those inhabitants of the United States who happen or prefer to reside far from the great publishing centers of the East. The more distant the residence, the greater the penalty.

When Congress was casting about during the war for sources of revenue, in desperation and ignorance it laid the axe to the root of the great publishing business and instituted a zone system on second-class postage, under which the national magazines are carried to all parts of the country. The system provides for increased postage varying directly with the distance from the point of publication; and inasmuch as the great publishing centers of the country are mainly in the East, it follows that Western subscribers are made to bear an inequitable burden. The country is sectionalized and a barrier is raised against the uniform dissemination of knowledge and information. The greatest force in the country for molding public opinion and creating solidarity of the people is thus handicapped in its efforts, and a part of the nation is the object of discrimination.

As we have remarked on former occasions, Congress does some things well, but revenue-raising is not one of them. The egregious folly of sectionalizing the country in a matter of postage is sufficiently apparent to the simplest mind that is open to conviction, and it would seem unnecessary to marshal arguments against a tax on literacy, intelligence and desire for knowledge. The publishing business of the country is ready to bear its just share of taxation for the support of the nation, and has gladly participated in all forms of revenue-raising proposed by the Government since the war began; but it is unable to see why, under the guise of taxing publications, the burden should be laid on subscribers in accordance with their place of abode. It would be interesting to hear the reply of a Congressman to this question. It might be illuminating if an Oregon subscriber to this journal should ask his Congressman why he will be obliged to pay nearly $3 per year postage in 1921, while his more fortunate friend in New Jersey may have the same service for only sixty-eight cents. Oregon is a delightful State in which to live, but if it is cut off from participation in national enterprise and progress, it must inevitably retrograde and lose prestige as a desirable place of abode.

When the zone system went into effect, July 1, 1918, the publishers of this journal decided to absorb the first increase, and spare the subscriber the burden in the hope that Congress would repeal the law. It must be obvious, however, that this cannot continue indefinitely,

since the tax really is not on the publishing business but on subscribers depending on their residence. With the incidence of the second increase, therefore, the publishers are going to make a temporary compromise and pass the tax on to those subscribers living west of the Mississippi River. Renewed efforts are to be made to enlighten Congress, and hope is not yet abandoned that we will be successful. If we are, the charge for extra postage will be removed; if not, it must ultimately be distributed strictly in accordance with the rates established by law. In the meantime it is inconceivable that Western subscribers to this and other national magazines will refrain from voicing their views to their Congressmen; and it is equally certain that Congressmen properly approached will give heed to the combined voice of their constituency. Congressmen sometimes appear to be reasonable or unreasonable according as their political fortunes are affected. Once it is realized that the tax falls on subscribers and not on publishers we believe the light of reason will prevail.

The First Great Step

THE census of chemicals imported into the United States during the fiscal year 1913-14, prepared by the Bureau of Foreign and Domestic Commerce in collaboration with the American Chemical Society, is now ready for distribution. A digest of its features, with illustration of the manner of presentation, is given elsewhere in this issue. We commend a study of the pamphlet to every chemist of the country who has the welfare of his industry at heart. It may humble his pride, but that will do him no harm if it also stimulates his ambition.

This piece of work is the greatest single contribution ever made to the promotion of the chemical industry in the United States, for it shows in cold figures the extent of our pre-war chemical dependence on foreign countries. It stands as a monument to nearly five years of unremitting effort, and represents the co-operation of five departments of the Government—War, Treasury, Commerce, Agriculture and the Interior—besides numerous Federal boards and the American Chemical Society, which proposed and supported the plan. Never before has any Government done as much for the support of its chemical industry, and it remains to be seen what American chemists will do in response. The Government has met them more than half way, and the next move is theirs.

Let American chemists realize clearly what this census is. In effect it constitutes Exhibit A in the indictment of American chemical industry for indifferent dependence on foreign sources of crude and fine chemicals. While the achievement of its publication is a matter for congratulation, its content is in reality a measure of our country's humiliation when war revealed the appalling extent of our unpreparedness. Here, then, is no subject for rejoicing, but rather of sober meditation and firm resolution to alter the status of 1914.

It is well known now that when war dislocated world trade, the United States found that it had been dependent on Germany for a great quantity and variety of chemicals. We came to this realization over night, as it were, and a great cry arose throughout the country for chemical independence. There was much ado over the advantage our foreign neighbors had gained while we slept, and there was a call for the chemical industry to awake. It is true that American chemists arose to the war emergency and acquitted themselves with credit. But the war is now over, the emergency is passed and the future is uncertain. Fortunately this census is published at an opportune time, for it will serve as a delicate reminder of the conditions of 1914, and an incentive to create a permanent well-rounded chemical industry in this country.

Do we really want chemical independence? The answer will be found in the extent to which we diminish the number of items in this census. If we are sincere in our pretensions we will undertake to manufacture those chemicals formerly imported, and do it in as great variety and quantity as possible. We will select not only those items which are plainly profitable, but will choose also those which are functionally and economically important if not financially remunerative. We will mix some patriotism with our brains and commercial enterprise, and carry a part of the load at little or no profit until we achieve that degree of profitable independence which must be our goal.

This census has been made for the good of the whole industry and not for private advantage and exploitation. The widest use must be made of it if we are to expect further governmental co-operation. The successful outcome of this work is an earnest of what can be accomplished by the chemists if the Government is convinced that the industry will profit by it. The machinery for continuing the work is in existence and the only possible excuse for failure to perpetuate it will be a lack of interest on the part of those for whom the work was done. The first great step toward American chemical independence has been taken. Will American chemical industry take the next?

The Chemical Foundation And Confiscated German Patents

THE Chemical Foundation has great potentialities, and we take it for granted from the high character of the gentlemen engaged in the organization that it has made no serious error in taking over substantially all German patents. Patents are property, and German-owned property is confiscate in this country. There is, or rather was, much more German-owned property in America than American-owned property in Germany, so that the balance is favorable.

With these postulates granted, the measure would appear to be ethically and prudentially sound, and we shall consider only two prudential features which we hope to see solved. We shall also make one unfavorable criticism.

A number of American leaders in industry conducted great manufacturing works in Germany. Owing to the proximity of European markets and better shipping facilities in former days from German ports, they conducted large export transactions from these branches. The present measure, which of course will be abundantly reciprocated, equips the Germans with a good start in the very lines of export trade that Americans have already built up, and in considering the future of American exports we must bear in mind an important loss from this source. The problem of adjustment will be difficult, although we are hopeful of its favorable solution.

A patent is a monopoly, and its original purpose was to encourage initiative in invention, but its usefulness

has extended beyond the inventor. Industry has developed so that economical manufacture is usually possible only on a large scale. And improvements are hard to introduce. To substitute a new article for one that is old and already produced in quantity involves, usually, a hard fight, and the cost of finding a market for a new thing, even though it is greatly desired, is expensive. Perhaps this should not be so, but it is. It comes from doing things on a large scale for purposes of economy in manufacture. Therefore, for the introduction of novelties a monopoly is almost necessary for a while, until the public is informed and the art of production is mastered. The present indefiniteness of the Chemical Foundation's licenses therefore detracts from their value. We understand that it is not the intention of the Foundation to grant licenses indiscriminately, to the encouragement of destructive competition, and we hope that in the definite plans of the organization this feature may be developed to the greater encouragement of licensees.

The administrators of the Chemical Foundation have a herculean task before them and it would be churlish indeed to heckle them in their deliberations. On one point, however, we think them open to complaint, and we do not hesitate to make it. In looking over the names of the directors we fail to find a single chemist in council. So far as we are aware there is not a man familiar with chemical industry to bring chemical understanding to bear upon its acts. This seems to us a proper ground for criticism, and with all good wishes we earnestly hope that the directors may soon correct the fault.

Readjustment And Resumption

IT WAS said that the people awoke one fine morning in the early fall of 1879 to find the country prosperous. In 1899 there was a remarkable boom in practically all industries, especially marked in the iron and steel industry. There have been various arguments to account for what occurred in 1899. One cause advanced was that it was the even 20 years after the 1879 performance. Another that has been suggested, particularly by those who of late have been predicting good business because it always follows a war, is that the 1899 boom followed the Spanish-American war. Another, so ingenuously simple as to command admiration at least, was that it came after five years of industrial depression had resulted in all necessary adjustments being made. Some have even suggested that the 1899 boom was caused by the Dingley tariff of July 24, 1897.

Why could not the precise cause be assigned? The revival was largely psychological. Men got tired waiting. Conditions had become favorable some time before, but people were lethargic, unsanguine, pessimistic, hopeless. Much readjustment occurred in the years 1873 to 1876 inclusive, and in the years 1893 to 1896 inclusive, but very little in 1877 and 1878 or in 1897 and 1898. Things would have started sooner if men had not been in such a hopeless mental condition.

Today, however, we have no such unfavorable mental state. Men are hopeful, enthusiastic, anxious to get to work. The mental attitude is going to make them start too soon, if anything, certainly not too late. When these starts are made, they are made suddenly, as was the case in 1879 and in 1899. Perhaps the starts are not really sudden, but they appear so.

At the close of the war it was said that resumption of normal peace time activities would follow readjustment. That was so simple as to be quite elementary. No one undertook to inform us how far readjustment would have to extend in order that resumption could occur, hence we have been in the position of waiting for the resumption, in order to reach the interesting but useless conclusion that readjustment had been completed. It is like asking when the night will be over and being told that all we need to do is to wait until it is daylight and then we shall know that the night is past. Such information is strictly accurate but not particularly useful.

All that we have learned is that we cannot expect, as many did expect, a return to pre-war conditions as to wage rates or commodity prices. There has been enough pressure upon prices of many commodities, through restriction in demand, and upon wages, through unemployment, to cause a very considerable yielding if that were really in order, but there has been very little yielding. We cannot expect more in the second six months after the cessation of war work than has occurred in the first six months, hence the psychological phenomenon of men growing tired of waiting is likely to be exhibited almost any time. These things may come suddenly, as has been suggested by the instances cited, and particularly so when men are enthusiastic, as they must be when peace becomes established.

We have been indulging in various theories as to readjustment and reconstruction, and changing our theories as conditions changed and showed that they were unsound. No right theory for this period ever will be developed, because there is none applicable. We cannot generalize with so few facts. One theory that is about to be knocked out, if indeed it is not already knocked out, is that construction work cannot begin until construction costs are greatly reduced. We have been saying that several years of work have piled up and must be done, yet many have assumed that the work cannot begin until conditions have been made favorable for doing the whole collection of jobs. We could not do several years' work in six months anyhow, and certainly there is some work that is more pressing than others, work in which the saving of time adds a value. Some ventures are based upon a large annual return and a short amortization period, others promising smaller annual returns but admitting of a much longer amortization period in the accounting. Given a steadily descending scale of construction costs, month by month, the first named class of jobs would be undertaken sooner than the second. Again, there is work in which actual cost is not the sole consideration. One who invests in a work of construction simply to secure a profitable employment for his capital is in a different class from one who has a pet theory to carry out, or some other personal consideration. There is the man for instance who wishes a better house in which to live. His life is passing and he may not be disposed to defer building a new house for himself because there is a prospect that he would save a few dollars out of each hundred by waiting one year or two years of his life for his new house.

Resumption, therefore, is likely to come suddenly and without much warning, marking the end of the preliminary readjustment, furnishing the first definite disclosure of the amount of readjustment needed. Afterward from time to time there will be other readjustments, as it becomes necessary to pave the way for the less urgent work that is waiting to be done.

Readers' Views and Comments

Flaky Structures and Their Possible Elimination

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with much interest the excellent paper by Prof. Haakon Styri on "Flaky Structures and Their Possible Elimination" in your May 1 issue. There are a few facts regarding the thermodynamics of the equilibria of the oxides of iron and manganese at high temperatures which I would like briefly to discuss. The method used by Mr. Styri is so simple as possibly to appear to constitute an entirely rigid treatment to those readers not familiar with the subject. Nevertheless, those same facts which prevent the treatment from possessing even theoretical exactness have occupied the attention of physical chemists for a long time, without the accumulation of sufficient data, so far, to enable the correct theory to be put into practice. I refer particularly to the rôle of specific heats in the calculation of high temperature equilibria from ordinary thermochemical measurements at room temperature.

Some time ago I had occasion to examine the literature bearing on the question of the equilibrium in the deoxidation reaction $FeO + Mn \rightleftarrows Fe + MnO$, which is, as evident, dependent upon two simple dissociation reactions, viz., $2FeO \rightleftarrows 2Fe + O_2$ and $2MnO \rightleftarrows 2Mn + O_2$. From an examination of the facts in the case it was concluded (1) that the existing specific heat data on iron, manganese and their oxides was insufficient to permit the calculation of these equilibria at high temperatures in even an approximate manner; (2) that there was no direct experimental proof that the above-mentioned deoxidizing reaction occurred, particularly in view of the existing doubt regarding the identity of ferrous oxide, FeO. Certain phases of this problem have been recently discussed by me elsewhere.[1]

Mr Styri does not call attention in his paper to the fact that the use of the approximate form of the Clausius-Clapeyron equation connecting the dissociation pressure, the heat of reaction and the absolute temperature involves the assumption that the heat of reaction is independent of the temperature. This is equivalent to taking the mean specific heat of FeO and MnO in the temperature range considered (approx. 20 to 1600 deg. C.) as equal respectively to the sum of the specific heats of Fe and oxygen and of Mn and oxygen. Le Chatelier[2] first called attention to the fact that the constant of integration in the approximate form of the Clausius-Clapeyron equation, when the dissociation pressure is 1 atmosphere, is quite often in the neighborhood of 32 in the case of simple dissociation of a solid, but that it varies some 7 units in either direction. Forcand[3] finds somewhat higher values. The subject is treated very thoroughly by Haber.[4] The use of the value 32 by Mr. Styri is probably as good a guess as any, since in the case of the oxides Fe and Mn no really reliable data are available. Even in the case of the thermochemical values for the heats of formation of FeO and MnO there undoubtedly exist considerable errors. Since LeChatelier's measurements were made (about 1896) considerable advances in calorimetry have occurred.

On page 480, Mr. Styri writes down the equation

$$\frac{p}{P} = \frac{a^2}{A^2}$$

where p = partial oxygen pressure at a concentration of FeO equal to a, P = partial oxygen pressure for a saturated solution of FeO in Fe, and A = solubility of FeO. In other words, the ratio of the partial oxygen pressures for two different concentrations of FeO is equal to the ratio of the squares of the respective FeO concentrations, at constant temperature (equal to 1600 deg. C. in this case). The next step taken is a transformation of the above equation, thus,

$$p = \frac{P}{A^2} a^2$$

Mr. Styri substitutes in this equation the values of P and A already deduced by him, and, instead of replacing A by the value for the solubility of FeO, he uses the value for the "oxygen" content of FeO, thereby making it necessary to express a in terms of the latter. He suggests the analysis of steel for oxygen as a method of determining a. Recent work by the Bureau of Standards[5] shows that the Ledebur method of determining "oxygen" in steel is of little practical value. This fact makes it certain not only that the actual oxygen content cannot be accurately determined by known methods, but also that LeChatelier's value for the solubility of FeO in steel, used by Mr. Styri in computing the constant A in the above equation, is nothing more at present than an admittedly inaccurate determination, with no intimation of how great an error may be involved. Taking into consideration all that has been said it is easy to see upon exactly what sort of experimental data the curves given in the chart on page 481 are based, and by what type of approximate theory they have been arrived at.

The danger which may result from the use of such a chart lies in the fact that, in view of its deduction from mathematical formulæ not fully understood by the average steel man, the conclusion may be drawn by such an individual that the physical chemistry of the deoxidation and allied processes is at present a complete chapter in our knowledge, thereby giving rise to an impression that further experimentation is mere repetition. As a matter of fact, what we actually know about the reaction $FeO = 2Fe + O_2$ is relatively little compared to what we do not know. The thermodynamics of the process is well known to all students of the subject. The mathematics of the case is easy compared with the difficulties of accurate measurements at these elevated temperatures. The sooner this important fact is fully realized and the necessary amount of labor given to the experimental side, the sooner will the science of metallurgy cease to be empirical and haphazard, and leap forward to its allotted position in the front rank of applied thermodynamics and physical chemistry.

This viewpoint seems reasonable when we consider the fact that at the present time our knowledge of the specific heat of iron extends only to 1100 deg. C.[6]; and that of manganese to 500 deg. C.[7]; while the data regard-

ing the specific heats of FeO and MnO are confined to measurements at room temperature. The specific heat of the common gases may be considered as fairly well established[5], even at high temperatures.

Such data as do exist, for the lower temperature ranges, show clearly that the change in the specific heats of Fe and Mn may exert a relatively great effect in determining the equilibria at high temperatures. These changes cannot be ignored. For instance, Laemmel' finds that the specific heat of Mn at 0 deg. C. is equal to 0.1072; at 500 deg. C. it is equal to 0.1652, an increase of about 54 per cent. Who can predict what is its value at 1600 deg. C. ?

To arrive at definite conclusions regarding these high temperature equilibria we must have data sufficient to make possible the use of the free energy equation in its complete form, or else succeed in making a direct determination of the equilibria. In the former case, we must have complete specific heat data, otherwise we are reduced to a state of unsubstantial assumptions and indefinite approximations. The latter solution, i.e., by direct measurement, appears extremely difficult but not entirely impossible. So far no one has attempted it in the cases under consideration.

Cleveland, Ohio. ALEX L. FEILD.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—It is sometimes an advantage, in order to raise discussion, not to treat a subject fully, and I am glad that Mr. Feild so strongly points out the necessity of determining the data we need for the accurate determination of the equilibria at higher temperatures. Besides the specific heat mentioned by Mr. Feild it is equally important to determine the oxygen and carbon content in equilibrium at higher temperatures and I agree that no known method for the determination of oxygen in the cold steel is satisfactory because no attention is paid to the oxygen which escapes during cooling and solidification. My statement of Pickard's analysis of 0.092 per cent O and of Shimer and Kichline's of 0.074 and 0.064 per cent O in overblown steel (by an error stated wrongly in my paper) as possibly representing the oxygen concentration in the steel for a certain slag should therefore be correspondingly modified.

In the writer's paper it was the intention to collect in as simple form as possible the influence of the different variables in steel refining. It might help others as it helped myself to get a clearer understanding of the reactions in the steel furnace and will aid in the prediction of what must happen to the steel when additions are made or the temperature changed. The value of determining the heat of combustion and the solubility of oxygen and carbon more accurately at the temperature considered will be to give the curves of my chart their correct position, which in all probability will be different from those presented, but the relative form of the curves must be the same. And even with great divergence from their correct values the curves will be useful in practice because we must remember that they represent equilibria and it will be in only extremely rare cases that such conditions are present in the steel furnace. Most of the time the conditions deviate considerably from the equilibria and we will correspondingly have different speed of reactions according to how far the system is from equilibrium; and knowing the conditions we can predict in what direction they will go.

With the unsatisfactory knowledge of the saturation concentration of oxygen at different temperatures I found it unnecessary, therefore, to try to calculate the heat of combustion at the high temperature by the help of the inaccurate specific heats, and for the same reason I refrained from publishing some otherwise interesting calculations of the influence of different slag concentrations. It was the writer's desire first to determine in actual practice how much the calculated curves would vary from concentrations found under certain conditions in the steel furnace and if possible under equilibrium conditions, and also to try to determine certain physicochemical data whereby the problem could be attacked from another angle. Both series of tests were started before the paper was published, but I regret to say that the progress has not been fast owing to lack of opportunity and time.

Mr. Feild notes the substitution of the oxygen content of FeO for the solubility A of FeO in formula 6, thereby necessitating the expression of a in the same terms. It was perhaps a little careless not to retain the numerical value of the solubility of FeO and calculate the O content from the found concentrations of FeO (a). But it is easy to see that the concentrations of FeO (A and a) vary from the concentrations of O only by a constant factor, the same in numerator and denominator, so no misunderstanding should occur since the explanation was given in advance.

The concentrations of O can just as well be used in the formula, since we do not know in which form the O is present in the liquid steel, whether combined with Fe and dissolved as FeO or dissolved as O. It is clear that whichever form it is, the partial pressure of the O must be equal to the dissociation pressure of the FeO with which it is in equilibrium, when we disregard the probably small influence of the partial pressure of Fe. The Art of Searching Chemical Literature

To the Editor of Chemical & Metallurgical Engineering

SIR:—In connection with the article on "The Art of Searching Chemical Literature" in this issue of your journal, may I call the attention of the National Research Council and especially of the committee on publication presided over by Dr. Stieglitz, to the desirability of a publication which shall provide what might be called a "General Index to Chemical Literature"? This would include the "art of searching literature" and provide at the same time a full and complete list of all special monographs, theses and works of reference to chemistry.

The instructive synopses of chemical treatises published by Mr. McClellan in the bulletin of the Carnegie Library serve a very useful purpose, and if these were made to embrace the entire chemical literature they would provide a volume of especial value.

Another point of interest is that up to the present the French chemical journal literature has not been readily accessible largely on account of the lack of good indexing. It is easy to understand why German authors have invariably failed to give proper credit to French investigators, and if some one well qualified

would undertake the general abstracting and indexing of this literature it would be of valuable assistance in promoting the advance of chemical knowledge and would serve to refute to a considerable extent the exaggerated claims of German chemists in many branches of the "art of chemistry."

The writer would also like to suggest to editors of scientific journals the advisability of printing on the outside cover of each issue the initial and final page numbers. By this means the necessity of having to glance through several issues could be avoided. Incidentally this is the scheme adopted by the *Chemisches Centralblatt.*

Railroad Research Work

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your editorial in the issue for April 1, criticising the "complete cessation of industrial research and of the development of natural resources of the territories served by the various railways," now that the railroads are being administered by the Government, puts me in a reminiscent mood. I can write freely because I have practically retired from business and can possibly speak with some authority, as I was Railroad Industrial Development Commissioner for over twenty-five years. I originated the Railroad Industrial Department; ultimately it spread over the entire United States and has been more or less established on all continents.

I laid my plans before the management of the Chicago, Milwaukee & St. Paul Railway Co. in 1891. They were accepted, and with "We have no instructions to give, develop our territory," I started out on my mission. I had been trained in the transportation business and had a hobby for the study of political economy. I knew that the traffic and operating departments had their hands full with current business from morning until night and had little or no time for research. I resolved to take adequate time, and for the first six months did nothing but travel over the entire territory looking out of the car windows and acquainting myself with the people and resources of the line. Space forbids lengthy details. I will merely give a few instances showing general plan of operation.

Shortly after entering the service of the St. Paul I read in the newspapers that the pine had been largely cut out in several parts of Michigan, that once flourishing towns in the lumber districts were going to pieces and that substantial residences could be bought for $5 apiece as salvage. We had similar pine territory in Wisconsin. Sawmills were more and more coming in, the railroad was doing an immense and profitable business hauling lumber, but I figured this could not last and in the end we would have a bonded streak of rust. This especially threatened the Wisconsin Valley Division, which parallels the Wisconsin River. This territory was practically one forest of hardwood, pine, hemlock and some spruce. The pine lands with standing timber were rapidly rising in price and selling on stumpage basis, that is, at so much per thousand feet of estimated timber on the land. The hardwood land was selling at $3 per acre with the trees on it and the hemlock lands were almost unsalable at $3 per acre, including the standing timber. I advertised for furniture, veneer, cooperage and kindred factories; went East and canvassed manufacturers to come West; aroused the local towns to invite such factories. They were secured; the cities themselves did most of the work of securing new industries.

There were water-powers galore running to waste all along the Wisconsin River. Thomas Nash, Assistant Postmaster General, who lived at Grand Rapids, Wis., owned a water-power at Nekoosa, Wis. He told me he would put in the power as capital stock if I could get an Eastern paper manufacturer with capital to put in a paper mill. I advertised in all the paper-trade journals, went East and canvassed the manufacturers at Holyoke, Bangor and other places. Several came West to look the ground over. Nash heard what they had to say, but none of them would bite. Nash spoke to Ex-Postmaster General Vilas, a Wisconsin man. "What is the matter with us all chipping in and starting a paper mill ourselves?" said Vilas. They did. The second year the mill was paying the St. Paul road a freight bill of over $85,000; it ultimately went over $100,000 per annum. In eleven years we had eleven large paper mills on the Wisconsin River, chiefly from local capital. One city emulated the other; all I did was beat the drum.

I told our immigration agent to direct Scandinavian farmers to the cut-over hardwood lands, which were selling cheap. Hardwood stumps rot in two years. Settlers came. Pine stumps take 75 years to rot. I helped the powder companies to start dynamite squads to show owners of pine stump lands how to blow out the stumps. Then I took the hemlock lands in hand, advertised for tanneries in all the Eastern tanning sections, canvassed tanners and got a big Boston firm interested. They looked the ground over and shipped two cars of tanbark to Boston. Good! They located a large tannery at Merril, Wis. After arranging for side-track there I took the train for Chicago. En route I met Mr. Nash on the train, told him I had just located a tannery at Merril, the tanners had bought a large tract of hemlock, they would use the bark, but there being no present market for the wood it would go to waste. Not so! Said he, "Look here," showing me a paper, "we have just received our patent for making sulphite pulp from hemlock. See that I get a freight rate and I will contract for the peeled hemlock logs." We made him the rate and the logs went to the mill.

At another point because of distance the iron pyrites were unsalable. I canvassed the situation and we secured a sulphuric acid plant on the spot. Mineral, special clay and other finds were investigated, often with permanent freight results. But enough said. In 1903 I went to the Erie Railroad as Industrial Commissioner and we put new plants on that line in the next eleven years that would extend continuously on both sides of Broadway from the Battery to Spuyten Duyvil.

I believe that the Industrial Department of the Southern Railway did more for the development of the South than the Federal and State Governments combined, and so with all other railroads. I visited South America last year and found that two railroads there had Industrial Departments. I dash this off with no idea of self-laudation but merely from an interesting experience to confirm what you editorially intimate, namely, that the industrial development and research work of the railroads had its place, is creative and ought to be continued. I hold that whether the railroads are privately owned or government owned, creative departments are national wealth-producers.

The American Chemists' Responsibility

To the Editor of Chemical & Metallurgical Engineering

SIR:—The Bureau of Foreign and Domestic Commerce has just published a little pamphlet compiled by it in collaboration with the American Chemical Society. This marks a new and unique phase in co-operation between government agencies and our industries; it displays a wholesome spirit of practical patriotism and good citizenship born of war conditions and which must continue and grow in order that pre-war conditions of avoidable national dependence on foreign countries for things chemical may never return. The Government's labors are for the present concluded; the chemists' responsibilities have only now assumed tangible, definite and concrete form. Whether this country shall become and remain chemically as independent as possible now rests squarely upon America's chemists and not elsewhere.

The American public has declared in unmistakable manner its demand that this country be chemically independent; this pamphlet tells our chemists the name, the quantity and the value of every chemical article imported into this country in the fiscal year 1913-14 (the last peace-year) and also what proportions of each article came from the various countries supplying it. American chemists are therefore now and for the first time fully informed and in great detail concerning the nature and scope of their task. They know the individual articles, the domestic business volume of each, the unit price they have to meet in almost each case and the competing countries. The Chemical Foundation by acquiring all enemy-owned U. S. patents in these fields has made it possible for American chemists to surmount any obstacles to progress toward chemical independence offered by those patents. No matter how large an export or domestic business our chemists may hereafter build up, if they do not reduce America's avoidable chemical dependence they will not have met the thoroughly proper demand of our public. Progress in export or domestic business, no matter how great, never can offset any avoidable national chemical dependence.

The functional value of articles in our national activities must be the paramount guide in making us chemically independent; mere size or volume of business is no safe index of national importance. A few thousand dollars will supply all the optical glass in all the microscopes, binoculars and the like used in this country. A few hundred dollars worth of assorted coal-tar dyes will supply all the needs of the nation's bacteriologists. A few thousand dollars worth of assorted stabilizers will make the country's total requirements of explosives, in peace and in war, safe to handle and to transport. A few thousand dollars worth of assorted synthetic remedies will care for the needs of the nation's afflicted. Since foreigners succeeded in making us dependent on them for these things, it simply cannot be that our chemists cannot make us independent in those respects.

Yet the task thus concretely set American chemists is, from a business point of view, not an easy one. Three thousand separate articles of chemical manufacture and of national functional importance, but totalling only about $60,000 in value, or $20 per year on the average for each article, were imported in 1913-14; hundreds of like articles worth less than $5,000 a year apiece were then imported. How can this business be profitably distributed over our many chemical factories without violation of our own long-standing laws? America's chemists must solve not only the chemical details of production and application of these many items of manufacture but also the law-problems which obstruct progress. They can solve the former by themselves; whether they can afford to carry them out in competitive commercial practice or not depends upon their success in obtaining proper remedial legislation, and in this they must have sympathetic and effective co-operation from both the public and our law-makers; but the chemists must take and maintain firm and concrete initiative on both branches of this single problem; anything less than that is bound to lead to disappointment.

Bucher Cyanide Process

To the Editor of Chemical & Metallurgical Engineering

SIR: In reporting the recent meeting of the American Chemical Society at Buffalo you state on page 394 that a paper on the Bucher Cyanide Process was given by R. O. E. Davis. This paper was by J. B. Ferguson of this Laboratory.

ROBERT B. SOSMAN,
Acting Director.

Geophysical Laboratory,
Washington, D. C.

Western Chemical and Metallurgical Field

Oxidized Copper Ores in Arizona

ONE reads in the annual reports of Arizonan corporations such statements as the following (Inspiration): "Oxide copper in mill feed 0.291 per cent; oxide copper in mill tailings, 0.253 per cent." Such a condition of affairs has caused general interest in some method whereby this elusive portion of the ore may be saved at a profit, to say nothing of its obvious application to the enormous known deposits of oxidized mineral.

A judicious combination of flotation and gravity concentration is apparently capable of making excellent recoveries of copper sulphides even in low grade ores—it may be rather unfair to quote 88.51 per cent from the Inspiration report as a mark to aim at. Consequently considerable attention has been given to "sulphidizing flotation," where by means of various reagents the oxidized particles are changed superficially to sulphides to a sufficient extent that they may be picked up by the bubbles in a flotation cell. Such a scheme was used at Hurley in the Chino Copper Co.'s mill with considerable success during the latter part of 1917. Also at Superior, the Magma company has been conducting careful and large-scale experiments with good results on the flotation of its oxidized ores. Whether the ore at Superior is more amenable to sulphidizing flotation than the general run of Southwestern ores is a matter of question—it is probable, however, that general adoption of this process will await its perfection to the point where a little inattention or a little incompetency will not throw the entire system out of balance. In other words, the impression exists that sulphidizing flotation is a delicate process which cannot yet be trusted to the average mill man.

Leaching is the apparent alternative. The only commercial operation in Arizona is at Ajo, but the signal success of this well-designed plant has strongly attracted other men with like problems to solve. Sulphuric acid, the solvent used at Ajo, is comparatively cheap and

can usually be manufactured locally from pyritic ores, while methods of precipitating copper sulphates either by electric current or on iron are quite efficient and perfectly well known by many operators. In an ore-body such as that of the New Cornelia Co., whose major mineral content is oxidized, it is obviously good engineering to leach out the acid-soluble mineral from coarsely ground ore, then follow by fine grinding to release the cleaned sulphides for flotation and gravity concentration. Movement of leach and wash solutions by displacement is feasible on granular material such as at Ajo; with finely ground material discharged from a flotation cell, counter-current decantation methods would probably prove equally satisfactory.

However, such fine tailings containing considerable quantities of clay or other like substances as experimented on at Clifton by the Arizona Copper Co. may involve the addition of so much expensive wash water as to eliminate profits altogether from the leaching operation.

While sulphuric acid is a good solvent for copper, it also attacks many other constituents of an ore to a greater or less extent, with the result that the solutions will become quickly fouled, among other undesirable effects causing a heavy loss in acid. Fortunately, experiments on 10-ton lots of Inspiration ore show it to be extremely well adapted to treatment by the Ajo system; i.e., leaching out oxides, fine grinding the residue and then floating sulphides. Following that company's semi-laboratory experiments, a unit with 35 tons daily capacity is nearing completion wherein complete information as to eventual mill practice will be obtained.

Decision as to actual construction is halted to a large extent, however, awaiting the publication of the tests being made by the Miami Copper Co. in co-operation with the Bureau of Mines. An experimental plant of considerable size was built during 1918 and operated satisfactorily for some time at the end of the year. Indicated revisions and additions are now in process of installation.

Publication of the details of this process is withheld pending completion of the test and clarification of the patent situation; however, it is generally known that the process consists of digesting the pulp with roaster gases and precipitating the clarified solution on iron. Digestion may evidently precede, follow or separate flotation operations according to particular conditions.

Heap-leaching of partially oxidized ore and low-grade capping is also receiving considerable attention. Large-scale operations on old tailings and California Hill capping are under way at Bisbee, while a large heap is being built by the Chino Copper Co. Possibly the most careful experiment is by the Phelp-Dodge Corporation at Tyrone, New Mexico, where several piles of various tonnages, depths and stratification are under observation.

Generally such piles are to be leached with mine waters discharged from precipitation tanks or launders. This water contains considerable ferric sulphate, a moderate quantity of copper and may be slightly acidulated—it is distributed over the surface of the pile—and after percolation is drained off to a recovery system. Periods of leaching and oxidation alternate, much after the methods used for years on tailings piles and ore heaps in Montana and Rio Tinto.

Beet Sugar in Utah and Idaho

Beet-sugar production in Utah and Idaho was discussed by men prominent in the industry at the April meeting of the Utah Society of Engineers. Sugar has recently sprung into great prominence in the two states, there being at present 23 factories in operating order and two more in course of construction, representing an investment of approximately $50,000,000, of largely local capital, this value being further augmented by agricultural land holdings, cattle and railroads. During the 1918 campaign about 2,750,000 bags of sugar (100 lb. each) was produced, valued at $24,500,000. Items of approximate cost production follow:

Sugar beets, 1,250,000 tons	$12,500,000
Coal, 160,000 tons	600,000
Lime rock, 100,000 tons	140,000
Coke, 12,500 tons	100,000
Bags, repairs, and miscellaneous items	1,750,000
Freight	1,250,000
Taxes	350,000
Payroll	3,500,000

Utah and Idaho factories are relatively small, having a cutting capacity of from 350 to 1200 tons of beets per day. As is possibly well known, sugar manufacture is not a complex operation; juices are extracted from the shredded beet, purified and evaporated, the sugar separated from molasses, then washed, dried and sacked. Chemical engineering problems are therefore confined largely to the handling of large quantities of hot solutions—which is almost universally done by closed impeller double-suction centrifugal pumps with a very deep stuffing box—and the evaporation of correspondingly huge volumes of water. Multiple-effect evaporators (3, 4, or 5-stage), with either vertical or horizontal tubes, are used for preliminary concentration, while crystallization is done in separate vacuum pans or candelaria. Naturally great attention is given to minimizing extraction- and wash-water and to boiler practice—sugar houses will have about 3 rated horsepower in tubular boilers capable of continuous large overload for each ten-day capacity. One pound of sugar requires from 0.9 to 1.3 lb. of bituminous coal for its manufacture, depending upon the efficiency of the thermal transfer and the sugar content of the beet.

Problems in industrial economy are dependent upon the fact that bulky beets should not be hauled great distances to a factory, on account of freight charges and the constant loss of sugar after digging. Small factories are therefore situated centrally in their contributing fields. Nine months out of the year the factory is closed and satisfactory part-time labor is rare during harvest time.

Sugar beets in proper quantity and quality represent the biggest problem of all. Here the factories are entirely dependent upon the farmers, and have only now awakened to the value of their good-will—or rather, the cost of their ill-will. Despite a large increase in price per ton paid the farmers, the sugar content is steadily falling to a dangerous minimum, while the shrinkage between wagon-scale and factory has nearly doubled in the last three years. For instance, whereas one of the larger Utah companies then received 6 per cent less beets than it paid for, last year it received about 11 per cent less. Doubtless a good share of this loss is due to natural shrinkage by evaporation of moisture and inversion of sugar by processes accompanying sprouting, still this particular company figured that it paid the farmers $260,000 in 1918 for their ill-will, for unwar-

rantable shrinkage caused by practices best known to the farmer himself.

Certain difficulties attend the successful maintenance of a schedule with beet farmers similar to that imposed upon metal miners. Doubtless perfectly satisfactory sampling methods could be worked out so that the farmer could be paid for the sugar actually delivered in the beet, but experience proves the unpopularity of this sort of contract. Farmers are in a somewhat different position from miners—if the latter do not care to accept the smelter schedule, about the only thing they can do is pack up and move into some other work. On the other hand, if a farming community decides not to raise beets, it simply plants a kitchen garden, and raises hay or grain. In other words, the sugar factory can be starved much more quickly than can the farmer.

Because of such considerations, corporation officials are seriously attempting to mold sentiment in their favor by all possible means. Co-operative profit-sharing even appears in the distance.

Interallied Chemical Confederation

THROUGH the initiative of the Société de Chimie Industrielle, an interallied chemical meeting, composed of delegates from Belgium, France, Great Britain, Italy and the United States, was held in Paris April 14, 1919, for the purpose of organizing an interallied chemical confederation. The American delegates were: Mr. Henry Wigglesworth, chairman; Dr. F. G. Cottrell, representing the National Research Council and the American Electrochemical Society; Lt.-Col. Bartow, of the American Institute of Chemical Engineers; Messrs. John Pennie and Charles MacDowell, counselors at the Peace Conference; Lt.-Col. Zanetti, Lt.-Col. Norris, Major Colin MacKall, Lt. Sidney Kirkpatrick and Mr. Donald Riley, representing the American Chemical Society.

A number of private meetings were held, presided over by Prof. Charles Moureau, president of the French Federation of Chemical Associations, at which were adopted the articles and by-laws of the Interallied Chemical Confederation for a close co-operation among Belgium, France, Great Britain, Italy and the United States. The status among the different chemical associations of the allied countries was agreed upon, and provision made for the possibility of permitting neutral countries to belong to the confederation. An interallied council board was elected, and it has been decided that the next meeting shall be held in London July 15-18, 1919.

During the public meetings of April 14-15 the following subjects were presented:

Prof. Henry Louis (Great Britain) spoke on the enrichment of iron ores by magnetic separation. Dr. Cottrell (United States) outlined American progress in the work on helium. Prof. Moureau, who was the first in France to show the existence of the sources of helium, and Mr. Georges Claude, the author of works on liquified air, presented remarks on the possible uses of helium. Mr. MacDowell (United States) spoke on the development of the American potash industry. Mr. John C. Pennie (United States) dwelt on the American patent laws, and Mr. Barbet suggested the enacting of an interallied patent law. Mr. Otlet, director of the International Office of Bibliography, closed the public meetings with an extremely interesting communication on the organization of the International Documentation.

After the customary dinners and after-dinner addresses the first interallied chemical meeting closed with a visit by the members to the devastated regions of Chauny.

The members of the council board who will meet in London next July are:

Belgium: Messrs. Chavanne and Crismer.
France: Messrs. Moureau and Paul Kestner.
Great Britain: Sir William Pope and Mr. Henry Louis.
Italy: Senator Paterno and Mr. Parodi-Delfino.
United States: Dr. Cottrell and Lt.-Col. Zanetti.

The general secretary is Mr. Jean Gerard, and the business address of the Confederation is 49, rue des Mathurins, Paris.

Chemical Exposition Plans

THE fifth annual National Exposition of Chemical Industries will be held this year in Chicago at the Coliseum and the First Regiment Armory during the week of Sept. 22, and as usual there will be a number of society meetings held jointly with it. The decision to hold the Exposition in Chicago was made unanimously by the advisory committee in consultation with the managers of the Exposition. One of the reasons for this change was the fact that the U. S. Army has commandeered Grand Central Palace for use as a hospital so that it would not be available for exposition purposes. Another reason was the keen interest shown in the Exposition by the Chicago section of the American Chemical Society, who felt that a Middle-West exposition would encourage development of the chemical industries in that part of the country. Indications are multiplying that the Exposition will be as successful as it was in New York, for all the space in the Coliseum and most of that in the Armory has been engaged.

A number of scientific and technical societies will meet in connection with the Exposition, among them being the American Institute of Mining and Metallurgical Engineers, American Electrochemical Society, American Ceramic Society and the Technical Association of the Pulp and Paper Industry. The Chicago section of the American Chemical Society will have headquarters at the Exposition and will probably hold a meeting. No other conventions will be held in Chicago that week so that adequate hotel accommodations will be available. The advisory committee and the managers of the Exposition are being assisted by a special Chicago committee consisting of Messrs. L. V. Redman, W. D. Richardson, A. V. H. Mory, Carl S. Minor, F. W. Willard and William Hoskins. The managers as in the past, are Charles F. Roth and Fred W. Payne, and the general office is at 477 South Dearborn St., Chicago, Ill.

Civil Service Examinations for Chemists

Catalytical Chemist, $3000 to $4000 a year; Assistant Catalytical Chemist, $2000 to $3000; Junior Catalytical Chemist, $1600 to $2000. Applicants for any of these positions, which are open to men only, must have had at least one year's experience in preparation and study of low temperature oxide gas catalysts.

On account of the needs of the service, applications will be received until further notice.

Spring Meeting of the New Jersey Chemical Society

IN spite of unfavorable weather about 100 members and guests of the Society met on May 10 at Rutgers College. The grounds, buildings and laboratories were inspected during the afternoon and dinner was served in Winants Hall in the evening. Prof. Ralph G. Wright, chairman of the entertainment committee, welcomed the members on behalf of the college and Johnson & Johnson, manufacturing chemists, of New Brunswick, who joined in entertaining the Society. Appropriate response was made by President Carleton Ellis. At the evening session a paper was read by Lieut. Joseph V. Meigs on the stability of automobile engine oils. By means of six well prepared experiments he showed the variation in the reaction when sulphur chloride is added to engine oils of various grades. He showed that medicinal mineral oil, being a highly refined product, reacted much more slowly than did other oils used for engine purposes. Turning to the lighter side of this subject, Lieut. Meigs said that it would be well if chemists would stand by the petroleum salesmen in their hour of trouble. One sales manager who was interested in fuel oils once stepped up to a factory chemist and asked him if it were not possible to get out an oil "that was free from carbon" because most of his customers complained that there was too much carbon in these oils. When told that some of these oils had 80 per cent of carbon in them, the excellent man went into a state of coma.

A scientific paper entitled "Oxidation and Reduction" was presented by Ernest T. Little, assistant professor of chemistry at Rutgers College. The author showed by means of carefully planned experiments that oxidation, as well as reduction, is not a molecular, but rather an electrical process. He pointed out that these two processes are influenced by four factors, namely: capacity, intensity, concentration and equilibrium. The capacity factor indicates the possibilities of oxidation for a particular oxidizing agent. The intensity factor is a measure of the strength of an oxidizing agent. It represents the driving force which determines whether or not the possibilities of oxidation are to be fulfilled. The oxidizing potential is determined by experiment and expressed in terms of volts. The concentration factor determines the potential which can be developed. Equilibrium is established when the oxidizing potentials of the reacting substances become equal to each other. In demonstrating these points, Prof. Little used a beaker (*A*) containing an oxidizing agent in acid solution and beaker (*B*)containing a salt of the lower state of oxidation (ferrous chloride). Platinum electrodes were inserted in each beaker and the terminals were attached to a delicate galvanometer. Electrical connection was established between the two beakers by means of a U-tube or salt bridge. As the oxygen passed from the permanganate solution to the ferrous chloride solution the galvanometer registered the passage of the current. The positive electricity acquired by the electrode in beaker (*A*) is carried through the anode to beaker (*B*) and there it oxidizes the iron to the ferric condition.

Members of the Society who desire to offer papers for the meetings of the Society in the Fall are asked to communicate with Dr. R. P. Calvert (chairman of the committee on program), care of Delta Laboratories, Arlington, N. J. The last meeting before the Summer will be held Monday evening, June 9, in Newark, N. J.

Census of Chemical Imports

THE census of chemical imports for the fiscal year 1913-1914,[1] prepared by the Bureau of Foreign and Domestic Commerce in collaboration with the American Chemical Society, is ready for distribution. It appears several months later than it was promised, but in view of the world conditions in the chemical industry the publication of the census at this time is most opportune. It comprises 2500 items of import valued at $100 or more, and gives for each the quantity, declared value and country of origin. The last is stated in percentage originating in each country where two or more are concerned. Five-sixths of our imports were crude and one-sixth manufactured materials. The compilation represents the labor of a staff of 24 persons for 10 months, reviewing the records of 110 ports of entry.

The report should be carefully studied. We have endeavored to give an idea of its content by compiling a few tables which are presented herewith. Table I shows the principal countries of origin arranged in order of value of our imports from them.

TABLE 1—PRINCIPAL COUNTRIES OF ORIGIN

	Value of Imports	Percentage of Imports Crude	Mfd.	Total
England	$48,235,931	24	20	23
Germany	47,507,937	15	41	19
Chile	19,734,353	10	..	8
Brazil	17,760,918	9	..	7
Belgium	17,534,449	8	4	7
France	13,102,249	..	30	5
Canada	11,840,612	6	..	5

In Table II we list 34 items of chemicals and allied products arranged in order of value of domestic production so that an idea can be gained of the relation of imports and exports to our own production. The groupings are arbitrary, and the fact that we are exceptionally strong in one or weak in another is a matter that can be thoroughly understood only by studying the basic conditions. On the whole, up to 1914 we had not progressed far from our custom of selling our products cheap and buying dear. Compare, for example, the marketing of our phosphate with that of German potash, and the conditions affecting international exchange of material will be seen to be something more than a difference in labor costs. Our wealth in oil products is clearly shown in Table II. Had it not been for this, we probably would have had nothing to trade for German coal-tar products and would have been forced long ago to rely on our ability and ingenuity instead of trading on our natural resources.

Importance of Nitrogen Fixation

Reference to Item 5, in Table II, shows an $18,000,000 difference between imports and exports of "chemicals." This difference is almost exactly equal to the value of our imports of Chilean nitrate, which adds emphasis to the economic importance of developing synthetic nitrate processes in the United States. Again referring to Item 5, it is interesting to note that the

[1] "Chemicals and Allied Products Used in the United States." By Dr. E. R. Pickrell, Department of Commerce. Misc. Series No. 82. Sold by the Superintendent of Documents, Government Printing Office, Washington, D. C. Price, 25 cents, or New York, 734 Custom House; Boston, 1801 Custom House; Chicago, 504 Federal Bldg.; St. Louis, 402 Third National Bank Bldg.; New Orleans, 1020 Hibernia Bank Bldg.; San Francisco, 307 Custom House; Seattle, 848 Henry Bldg.; Cleveland, Chamber of Commerce; Cincinnati, Chamber of Commerce; Cincinnati, General Freight Agent, Southern Ry., 96 Ingalls Bldg.; Los Angeles, Chamber of Commerce; Philadelphia, Chamber of Commerce; Portland, Ore., Chamber of Commerce; Dayton, Dayton Chamber of Commerce.

countries of origin and their respective percentages are as follows: Chile, 37; Germany, 23; England, 13; France, 8; Italy, 5; all others, 14.

In Table III we have selected 50 out of the 2500 items and have arranged them in order of value of imports. It will be noted that 8 of them, namely, sodium nitrate, ammonium sulphate, glycerine, argols, platinum, platinum products, magnesite and sodium cyanide were imported to the value of more than $1,000,000 each.

Many of the products imported are not commercially important. Thus there are 3000 "orphans" that were imported to a value of less than $100 each. Many of these, however, are functionally important in certain of our industries and it is quite as essential to the chemical independence of this country that these materials should be produced here as it is that we should avoid dependence on Germany for about $1,000,000 worth of sodium cyanide. Imported trikresol, for example, was used by our antitoxin manufacturers before the war as a preservative for their products. It took them some time to learn that this simple tar-acid fraction could be made in their own laboratories almost as easily as distilled water and it will be very much to their discredit if they are ever again dependent on foreign sources for this material. In like manner manufacturers must take an equal interest in items that are of small financial but of great economic importance.

In studying this census the reader must remember that it represents conditions in 1914 and that great industrial changes have occurred since then. Our regular 5-yr. census of manufactures covering the year ending June 30, 1919, will indicate the domestic growth of our chemical industry. When those statistics are available, we can proceed with greater light, but in the meantime the census of imports shows very clearly the extent of our dependence and the direction in which domestic industry must expand.

A careful study of the census may reveal errors or may suggest improvements. Reasonable criticism of any nature is welcomed and should be sent to Chairman of the Import Statistics Committee, American Chemical Society, 35 East 41st St., New York City.

TABLE II—SEQUENCE OF IMPORTS, DOMESTIC PRODUCTION AND EXPORTS

	Imports	Domestic Production	Exports
Oils, mineral	$13,233,057	$362,573,653	$124,322,660
Coal-tar products	8,818,944	220,238,000	35,359
Oils, vegetable	43,467,881	192,582,100	15,913,901
Clays	1,985,006	190,688,000	3,923
Chemicals	48,278 93	173,269,000	19,859,009
Fertilizers	28,038,709	153,196,000	12,111,108
Medicinal preparations	1,289,608	150,473,000	6,788,806
Soap	788,570	106,994,620	4,941,707
Gums and resins	88,903,829	205,282	3,790,874
Paints	20,836	70,582,461	1,104,971
Oils, animal	1,033,851	51,380,313	851,142
Explosives	.....	39,645,382	2,785,633
Varnishes	64,066	36,142,256	1,038,864
Salt	423,322	34,804,683	550,380
Greases and tallows	1,726,971	29,820,000	5,049,814
Pigments	2,240,320	27,386,665	3,728,331
Oil cakes	117,104	2,191,610	21,667,672
Turpentine and rosin	28,818	21,463,890	19,882,165
Dyeing materials	995,191	20,620,000	370,676
Cosmetics	2,309,827	19,160,407	1,638,841

Bronze powder	406,649	.....	.....
Total	$267,480,785	$2,017,794,065	$265,019,278

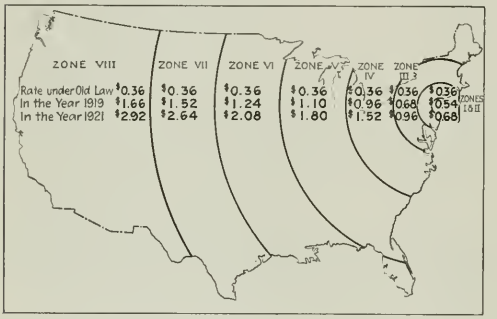
TABLE III—CHEMICAL IMPORTS IN ORDER OF VALUE

	Weight	Value
Sodium nitrate, long tons Chile, 99.5 per cent	564,061	$17,951,455
Ammonium sulphate, lb. Scotland, 46.7; England, 22.2; Germany, 19.1; Canada, 7.3; Belgium, 2.6 per cent	166,753,754	4,888,563
Glycerine, lb. France, 30.8; England, 28.7; Belgium, 7.3; Netherlands, 7; Russia, 5.4; Germany, 5.2; Spain, 4.6; Canada, 3.7 per cent	36,409,619	4,486,415
Argols, crude, lb. Italy, 46.6; France, 33.6; Portugal, 14.4; French Africa, 3.2 per cent	29,523,714	3,201,177
Platinum, fabricated, oz. Germany, 53.2; France, 29.7; England, 17.1 per cent	54,852	2,445,038
Platinum, crude, oz. Germany, 37.2; Colombia, 30.5; England, 17.4; France, 12.1 per cent	40,634	1,489,208
Magnesite, crude calcined, lb. Austria-Hungary, 92.8; Netherlands, 2.9; Greece, 2.2; Germany, 1.8 per cent	289,494,316	1,473,207
Sodium cyanide, lb. Germany, 89.9; France, 7.3; Netherlands, 1.3 per cent	8,523,867	1,243,438
Fusel oil, lb. Russia, 36.2; Germany, 18.2; England, 15.7; Austria-Hungary, 12.7; Belgium, 8.1; Ireland, 2.6 per cent	5,802,360	910,759
Casein, lb. France, 57.6; Argentina, 22.3; England, 9.6; Germany, 4.3; Canada, 2.9 per cent	10,798,614	705,264
Quinine sulphate, lb. Netherlands, 51.9; Danish East Indies, 26.7; Germany, 21.1 per cent	2,356,621	515,581
Calcium citrate, lb. Italy, 84; British West Indies, 15.6 per cent	3,097,265	493,738
Ammonium chloride, lb. England, 49.5; Germany, 48.3 per cent	9,076,729	465,429
Iodine, lb. Chile, 100 per cent	195,087	433,498
Oxalic, lb. Germany, 78.6; England, 10; Norway, 9.1 per cent	8,595,064	425,008
Sodium chloride, lb. England, 34.1; British West Indies, 28.3; Italy, 16 per cent	3,076,071	423,322
Bleaching powder, lb. England, 73.2; Germany, 21.7; France, 4.3 per cent	47,657,606	420,533
Yellow K prussiate, lb. Germany, 54; England, 27.6; France, 7.9; Netherlands, 7 per cent	3,508,225	390,050
K_2CO_3 refined, lb. Germany, 58.5; England, 16.6; Austria-Hungary, 9; France, 6.8; Turkey, 5.4 per cent	10,420,368	368,324
Sulphur, long tons Japan, 94.9; Italy, 3.8 per cent	19,398	$355,450
Thorium nitrate, lb. Germany, 99.5 per cent	147,885	337,700
Barium dioxide, lb. Germany, 45.8; England, 42; Belgium, 12.2 per cent	6,085,909	330,142
Potassium hydroxide, lb. Germany, 90.5; Austria-Hungary, 4.7; France, 2 per cent	8,395,049	320,753
Citric acid, lb. Germany, 57; England, 27.7; Italy, 12.8 per cent	652,410	304,438
Caffeine, lb. Germany, 97.7; England, 2 per cent	95,666	301,078
Potassium carbonate, crude, lb. Germany, 38.1; Russia, 19.7; Belgium, 18.1; France, 16.4; Austria-Hungary, 6.1 per cent	9,042,754	239,691
Zinc dust, lb. Germany, 74; Austria-Hungary, 20; Canada, 3.3 per cent	4,917,667	228,163
Tartaric acid, lb. Germany, 39.5; England, 19.8; Italy, 16.3; Austria-Hungary, 9.1; Netherlands, 8; France, 7.2 per cent	906,764	218,915
Mercury, lb. England, 72.5; Austria-Hungary, 11.9; Germany, 10.1; Italy, 5.4 per cent	444,896	192,768
Sodium yellow prussiate, lb. England, 71.9; Netherlands, 11.4; Belgium, 5.9; Switzerland, 4.2; Germany, 3.7 per cent	2,295,921	171,843
Palladium, oz. England, 83.8; Germany, 12.2; France, 4 per cent	3,986	169,171
Cream of tartar, lb. Germany, 100 per cent	827,746	159,972
Iridium, oz. England, 37.2; France, 34; Germany, 25.4 per cent	2,191	155,262
Ammonium nitrate, lb. Norway, 80.2; Belgium, 17.1; Denmark, 2.6 per cent	2,765,960	132,995
Santonin, lb. Germany, 100 per cent	5,239	125,360
Sodium hydrosulphite, lb. Germany, 100 per cent	505,232	116,197
Potassium nitrate, crude, lb. British India, 96.8; Germany, 3.2 per cent	3,546,580	115,344
Potassium cyanide, lb. Germany, 77.6; England, 22.3 per cent	808,721	113,199
Arsenic trioxide, lb. Germany, 33.1; Canada, 30.9; England, 23.6; Austria-Hungary, 6.3; Belgium, 6.1 per cent	3,034,070	110,168

Postal Penalty on Western Readers

THE accompanying outline map of the United States has been drawn to show the postal zones for second-class mail matter, and the cost of mailing CHEMICAL & METALLURGICAL ENGINEERING to subscribers in different parts of the country. Under the old postal law, national magazines and newspapers were mailable to any part of the country at the uniform rate of 1c. per lb. War-time legislation by Congress repealed this law and instituted a zone system under which the postage on second-class matter increases directly with the distance from the point of publication. The law did not levy the full penalty during the first year, but provided for annual increases in 1919, 1920 and 1921. The publishers of this journal absorbed the increase for the first year, but cannot continue that practice for obvious reasons.

Even a casual study of the figures is enlightening. Under the old law, annual postage on this journal cost 36c., regardless of the destination. A subscriber in



Oregon had equal privileges with one in New Jersey; but this year it will cost $1.66 to mail this journal to an Oregon subscriber for a year, and only 54c. to one in New Jersey. And that is not the full effect of the law, for in 1921 the respective costs rise to $2.92 and $0.68. It must be apparent that these costs cannot be absorbed by the publisher, considering the nominal subscription price charged. They must be passed on to the subscriber, constituting, in effect, an increased subscription price.

Congress should repeal the postal-zone law, and the reading public everywhere can bring about such action by calling the attention of Congressmen to the penalties which are to be imposed on subscribers. By way of compromise, until it can be ascertained whether Congress can be prevailed upon to repeal the law, CHEMICAL & METALLURGICAL ENGINEERING will charge extra zone postage of 50c. per annum to those subscribers living west of the Mississippi River. If the law is not repealed, it is evident that we will have to revert to the practice of half a century ago and charge all subscribers a flat price "plus the postage."

Johns Hopkins Scholarships

Through the generosity of the late Mr. William H. Graflin of Baltimore, a scholarship, to be known as the Graflin scholarship, and three assistantships have been established in the department of chemistry of the Johns Hopkins University.

The Graflin scholarship will be awarded annually to a candidate having a training equivalent to that leading to the Ph.D. degree and who therefore has had experience in research. It may be awarded twice to the same candidate. The holder of the scholarship will receive $1000 a year and will be expected to devote his entire time to research.

The three research assistantships each pay $750 a year and are open to chemists having the equivalent of a Ph.D. degree. The holder of a research assistantship will not be required to do any formal teaching, but will be given the opportunity to devote his entire time to research and to assist in the direction of research.

Applications for the year 1919-1920 should be sent to the Department of Chemistry, Johns Hopkins University, 321 Druid Hill Ave., Baltimore, before Aug. 1.

Business Training for Engineers

THE Commissioner of Education has issued a call for a public conference on business training for engineers and engineering training for students of business. This conference, national in scope and in character fully representative of all interests, will be held at the New Willard Hotel in Washington, Monday and Tuesday, June 23 and 24. All educational institutions, commercial organizations, and educational and engineering societies will be invited to co-operate. Engineers, educators and business men will be invited to discuss the following major topics: Business Training for the Engineer; Engineering Training for Commercial Enterprises; Significance of the War Experience for Engineering Education; Training of the Engineer for Overseas Engineering Projects.

The Commissioner of Education has called this conference on behalf of the Conference Committee on Commercial Engineering appointed by him, the chairman of which is Dr. Glen Levin Swiggett, specialist in commercial education of the Bureau of Education, and chairman of the Committee of Fifteen on Educational Preparation for Foreign Service. This committee is composed of administrative professors in engineering and commerce from several of the larger educational institutions and representatives from the Society for the Promotion of Engineering Education, the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Institute of Mechanical Engineers, the American Institute of Mining Engineers, and the Committee of Fifteen on Educational Preparation for Foreign Service.

Chemical Service for Latin America

The Bureau of Foreign and Domestic Commerce, Washington, D. C., is in search of a chemical engineer who has a knowledge of business and markets that will qualify him to make a survey of chemical and allied markets in Latin America. Those who consider themselves qualified to perform this service for the Government are invited to make application to the Bureau on blanks which will be furnished for that purpose. An eligible list will be prepared from these applications and examination will be given for the final selection of a proper agent. The salary will be $10 per day, with $4 allowance for subsistence. Transportation expenses will be paid. It is proposed to send the agent to Latin America July 1.

The Boston Meeting of the American Institute of Chemical Engineers will be held June 18-21, with headquarters at the Lenox Hotel. The program for this meeting was published in our last issue.

Kingsport, Tennessee, and Its Chemical Industries—I

A Brief Historical Survey of a Progressive Young American City, With a Technical Description of Its Varied Chemical Plants and Their Processes—Low Power Costs—Large Ceramic and Cement Plants

KINGSPORT is located in the northeast corner of Tennessee, in Sullivan County, on the South Fork of the Holston River, eight miles south of the Virginia line, twenty-six miles west of Bristol and the same distance north of Johnson City. The two latter cities are served by the main line of the Southern Railway, and from Bristol Kingsport may be reached by automobile in an hour and a half, or from Johnson City by an hour's travel on the Carolina, Clinchfield & Ohio Railway.

In 1910 there were on the present site of Kingsport only two farmhouses, and the population of the old town of Kingsport, two miles away from the present site, was 200. On Jan. 1, 1915, there were 900 people in the present town of Kingsport. At the beginning of 1919, four years later, a conservative estimate placed the population of the rapidly growing city at 10,000.

Numerous communities in different parts of the United States have flourished prodigiously during the war, and one might reasonably suspect, at first, that Kingsport's prosperity has been due to war's demands, and that now, with peace in sight, Kingsport will die the death. But if you ask the people at Kingsport, they will tell you that the war has held Kingsport back, and that henceforth, unhampered by the restraints on trade and commerce imposed by war-time restrictions, Kingsport will forge ahead more rapidly than before.

It was in 1915 that it was first foreseen that destiny had decreed that a city of some magnitude would be erected at Kingsport. Foresight was linked with forethought, and in that same year, with a population of less than 1000, it was decided to plan for a city of 50,000, and a professional city planner, Dr. John Nolen, of Cambridge, Mass., was engaged to lay out the design for a city on that basis. Dr. Nolen is still engaged by the city of Kingsport, and the city's growth is being guided by him.

City Divided Into Zones

Definite sites have been set aside for factories and industrial plants, and ample provision has been made for parks, playgrounds, rest-places, schools and churches, and sensible building restrictions have been adopted, applying to community sections. The city has been definitely divided into zones for manufacturing, wholesale trade, retail trade, and residences, and the benefits of the foresight exercised in this direction have already been felt.

The charter of Kingsport was drafted by the Bureau of Municipal Research of the Rockefeller Foundation. The town government consists of five councilmen, or aldermen, elected by the people at intervals of four years, and the five councilmen elect one of their number to be mayor. As it is possible that any one of the five councilmen might become mayor, a result of this system is that the people exercise more than usual care in their selection of the men who are to constitute the city council. The mayor appoints a city manager, who need not be a resident of the city or State. The latter appoints and dismisses all other employees of the city. The mayor presides at meetings of the City Council. and is the chief executive officer of the city. He also appoints the school board, two women and three men.

The School System

The school system is designed after the system of Gary, Ind., and practical education is a prominent feature. Cooking, sewing, home-nursing, fundamentals of chemistry, bookkeeping, typewriting, shorthand, manual training and agriculture are taught. There is also a play teacher for the little children, and every child is taught vocal music. Around the school-houses there are four acres of playgrounds. There is now one school building, for both graded and high schools, but two new schools have been authorized—both primary schools. In six years the school population has grown from 35 to more than 1000.

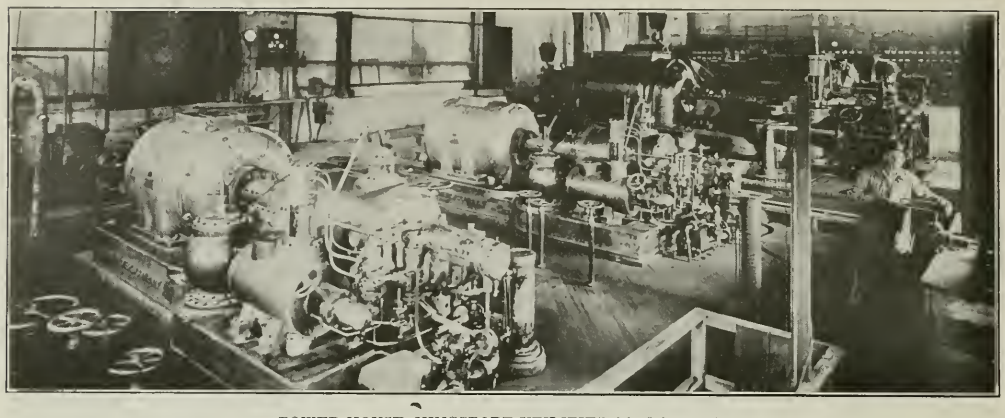
Kingsport has six churches; a modern police department; a volunteer fire department, whose members sleep in a hall with furnished rooms, provided by the city for their use; and a hospital, municipally operated, with accommodations for forty patients. There are four miles of concrete-paved streets of unusual width, built at a cost of $1.35 per sq.yd. of which the owners of abutting property pay three-fourths, and the paving of other streets with concrete is now under way, all cement, sand and stone being obtained within the city limits. The streets are flanked with wide concrete sidewalks.

A civic center has been provided, centrally located, with ample space reserved for all necessary public buildings. The planting of trees and shrubbery is being done under the direction of a trained landscape engineer, Harlan P. Kelsey, of Salem, Mass.

The Kingsport Improvement Corporation

A city could hardly have been designed and then built according to design with so much of intelligence and foresight, unless under the direction of some definite authority or power, continuous, at least thus far, in its existence. The sensible development of Kingsport is easily traced to the Kingsport Improvement Corporation, of which Blair & Co., bankers, of New York City, are the owners, with J. Fred Johnson, the chief executive of the corporation at Kingsport, as president. The Improvement Corporation owns the Kingsport Utilities Corporation (a power company to be described later) and much of the real estate in and around Kingsport. The Improvement Corporation is giving special attention to the housing of the population. The company builds houses, and either rents or sells them at cost plus a charge of $200 or $300 for the lot, giving terms to the purchaser extending over a period of four or five years. The Improvement Corporation is also interested in developing recreations for the inhabitants, and is now constructing an 18-hole golf course, under the direction of an expert from New York City.

After assigning to the Kingsport Improvement Cor-



POWER HOUSE, KINGSPORT UTILITIES CORPORATION

poration as much of the enterprise, progressiveness and determination as is its due, the fact remains that without some *raison d'être* Kingsport could not continue to thrive. Enthusiasm alone may boom a town for a while, but enthusiasm without substantial merit will not keep it booming. Kingsport has a variety of large industrial plants—a dyestuff and chemical plant, a wood alcohol plant, a cement and lime plant, a tannery and tannic acid factory, a brick plant, a wood pulp mill, a hosiery mill and a gas shell-loading plant. What induced all of these industries to locate in Kingsport within the past few years? And why, now that the war is over, does Kingsport continue to grow—on what do the people base their expectations that now progress will be more rapid than before?

Cheap Power Available

The outstanding advantage afforded to manufacturers is the opportunity for cheap power. The price of coal delivered at Kingsport for the five years preceding the outbreak of the war was $1.55 per ton. The ante-bellum price for power generated from this coal was five mills per kilowatt. Another natural advantage is the water of the Holston River. The river being fed by mountain streams, the water is unusually cold, and is useful for condensing purposes. The water is, moreover, remarkably pure—no softening is needed, and the amount of scale found in the boiler tubes is practically *nil*. Again the raw materials for making brick and cement being within the city limits, a brick plant and cement mill are already operating, and timber of many descriptions abounds in the vicinity. Building materials, therefore, are unusually cheap, and these materials are of the very best. The abundance of chestnut, oak and hemlock is responsible for the establishment of a tanning extract plant and a tannery, and the waste wood chips of the extract plant, combined with the ample supply of such woods as poplar, black and sweet gum, and maple were sufficient incentive for constructing a pulp mill. The hardwoods already mentioned, together with the beech and hickory, were the attraction for a wood-alcohol plant. All of these plants co-operate locally with one another, but the cycle of industries is not complete. Some of the resources of the Kingsport district are still undeveloped. Ten miles away there is an extensive deposit of silica, said to be 99.65 per cent pure, which is claimed to be useful for glass making. There are also in the vicinity valuable deposits of feldspar and kaolin. Other industries that Kingsport is reaching out for are a charcoal iron furnace to utilize the charcoal produced by the wood-alcohol plant; a packing house to foster the native cattle raising industry; a fertilizer plant to utilize the refuse of the tannery and the proposed packing house as well as the potash and phosphate bearing minerals of this section and also to furnish cheap fertilizer for the surrounding agricultural district; a cyanamide or lime-nitrogen plant; and a calcium carbide plant.

Kingsport Utilities, Inc.

Inasmuch as the chief attraction for industrial plants at Kingsport is the cheap power, a description of these plants may properly begin with the Kingsport Utilities, Inc., which furnishes power to all of the local plants, as well as to Gate City Quarry, 7½ miles away, over a 13,200-v. line. The corporation also lights the city of Kingsport.

Kingsport Utilities, Inc., was established in 1910. The capitalization is $500,000 common stock, $500,000 preferred, and $500,000 bonds. The original capacity was 3500 kw., which was increased in 1916 to 11,500 kw. The boiler equipment consists of four 600-hp. Edgemoor boilers, 250-lb. pressure, four 300-hp. Babcock & Wilcox boilers, and four 300-hp. Heine boilers, equipped with boiler feed pumps, feed water heaters, coal and ash handling machinery, etc.

Electrical Equipment

The electrical equipment comprises two 4000-kw. Allis-Chalmers turbo generators, 6600-v., 3-phase, 60-cycle; one 2000-kw. turbo-generator of the same make and voltage; and two 750-kw. Allis-Chalmers turbo generators, 440 v., stepped up to 6600 v. through transformers. The entire plant runs in parallel. Power is sold at "cost-plus basis." The cost of power to the various industrial plants is to-day about 1c. per kilowatt. About 4000 kw. of the total capacity is at present not utilized, but extensions now in progress at some of the industrial plants will soon absorb this surplus power. The corporation is prepared to enlarge its plant to any capacity that may be needed.

At the present time the cost of coal at the mine is $2.36 per ton, and freight to Kingsport is 58 cents. This coal comes from the Clinchfield district of Virginia. The following table gives complete information regard-

ing the analysis and fuel value of the principal coals of this region:

ANALYSIS OF CLINCHFIELD COALS

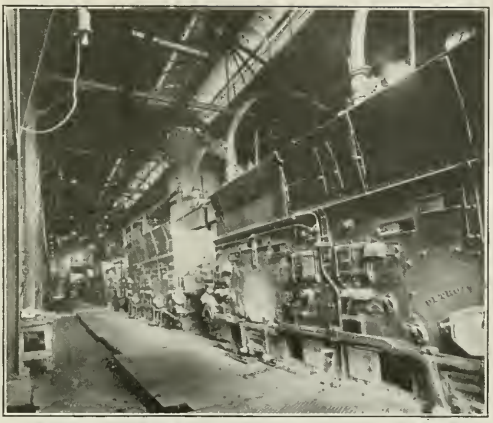
Coal Seam	Upper Banner	Lower Banner	No. 4 Seam
Proximate Analysis			
Moisture 105 deg. C.	0.95%	1.00%	0.50%
Dry Coal: volatile matter	36.95%	35.30%	32.70%
Dry Coal: fixed carbon	55.95%	57.80%	60.80%
Dry Coal: ash	7.10%	6.90%	6.50%
	100.00%	100.00%	100.00%
B.t.u. det'd.	14,560	14,660	14,580
Ultimate Analysis			
Hydrogen	5.25%	5.60%	5.10%
Carbon	80.10%	80.00%	79.80%
Nitrogen	1.55%	1.50%	1.60%
Oxygen	5.40%	5.20%	6.40%
Sulphur	0.60%	0.80%	0.60%
Ash	7.10%	6.90%	6.50%
	100.00%	100.00%	100.00%
B.t.u. calculated	14,510	14,740	14,580
By-Products			
Coke, lb. per ton	1,568	1,613	1,658
Gas, cubic feet per ton	10,000	10,000	10,000
B.t.u. per cu.ft.	600	600	600
Tar, gal. per ton	12–14	10–12	8–10
Ammonium sulphate, lb. per ton	22	20	20

The normal coal consumption of this power plant is 225-250 tons per day. The water used in the boilers comes from the South Fork of the Holston River, which flows within 100 yd. of the plant. This water is so free from scale-forming impurities that when the boilers are cleaned every ninety days, a scale of $\frac{1}{32}$ to $\frac{1}{16}$ in. in thickness is all that is found.

The Water Supply System

Kingsport Utilities, Inc., also owns the water supply system for the city of Kingsport. An impounding reservoir of forty acres, holding about 275,000,000 gal., is fed by various mountain streams. This reservoir is located $7\frac{1}{2}$ miles from Kingsport, with an elevation above the city of 590 ft. There are two reducing valves on the pipe line to the city, to reduce the pressure to 135 lb. There are 20 miles of water main (10 in. to 4 in.) in the city.

This water is piped to all of the industrial plants for fire protection and for drinking purposes. A filtering plant is now being installed, with a capacity of 1,000,000 gal. per day, and provision for an increase to 4,000,000 gallons.



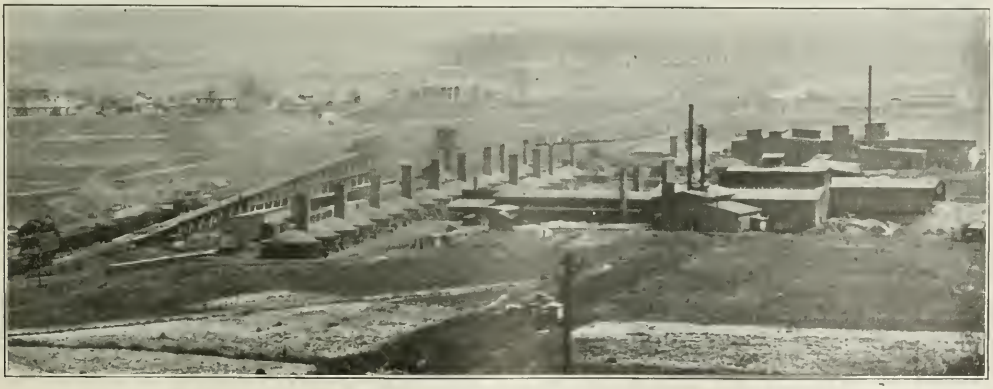
BOILER HOUSE, KINGSPORT UTILITIES CORPORATION

Kingsport Brick Corporation

The Kingsport Brick Corporation, established in 1910, was the first industrial organization to locate in Kingsport. The products of this plant are sewer pipe in all sizes from 4 in. to 24 in.; common red shale brick, face brick, "rugs," "newstiles," "textiles," radial chimney blocks, hollow building blocks, and chemical brick. The capacity of the entire plant is 150,000 bricks a day.

The plant is built near an unlimited supply of shale, the analysis of which is similar to that of the shale used by the Clinchfield Portland Cement Co., which is quoted farther on. The shale or clay is mined by steam shovel within 1000 ft. of the works, and is loaded on cars which are drawn by wire rope on a narrow gage track into the mill building. The clay is unloaded from the cars to a conveyor belt by which it is conveyed to a 9-ft. "dry pan," where the clay is ground to about 16 mesh. It is then passed through a 16-mesh screen, called a "piano wire screen," the wires running in one direction only, and the screened clay to be used for making sewer tile goes to the "wet pan," while that for making bricks goes to a pug mill. The process of making sewer tile will be described first.

In the wet pan the clay is mixed with a suitable quantity of water, and is then elevated to a belt 3 ft.



KINGSPORT BRICK CORPORATION

wide, called the slow feeder. This dumps the clay into a hopper called the fast feeder, which is handled intermittently to charge the sewer pipe press. When the slow feeder has delivered to the fast feeder a sufficient quantity of clay, an operative quickly shoves the fast feeder over, and delivers the charge of clay to the press. The sewer pipe press, manufactured by the American Clay Machinery Co., Bucyrus, Ohio, has various capacities, according to the size of the pipe being manufactured, as follows:

Capacity, in Number Lengths	Diameter of Sewer Pipe, In.	Length of Sewer Pipe, Ft.
5000	6	2.0
4000	8	2.5
3500	10	2.5
3000	12	2.5
2500	14	2.5
2000	15	2.5
1800	16	2.5
1500	18	2.5
1200	20	2.5
1000	24	2.5

In the sewer pipe press the clay is shaped into the desired size and length, and the lengths are then dried at 100 to 200 deg. F. for from four days to a week. Odd shapes of sewer pipe, such as short elbows, reducers, etc., are molded in plaster of paris molds. Sewer pipe and drain tile are burned in the kilns for five days. For 3½ days the temperature is brought up gradually, finally reaching about 2000 deg. C., and that temperature is continued for a day and a half. Salt is then added in the proportion of 150 lb. to a kiln, and firing is stopped. In some cases salt must be added twice. After 30 min. of "soaking," the kiln may be cautiously opened. It is then allowed to cool down gradually, about five or six days being allowed for the cooling processs.

For the manufacture of brick, the ground and screened clay is elevated by bucket elevator, and then is discharged into a hopper which feeds a pug mill. Here the necessary amount of water is added to give the batch the right consistency, and the damp clay then passes to the brick machine (also manufactured by the American Clay Machine Co., Bucyrus, Ohio), where the mass is molded into a long, rectangular, horizontal column, which passes on to a wire brick cutter, made by E. M. Freese & Co., Galleon, Ohio.

By means of the wires on this cutting machine the clay column is cut into individual bricks.

The bricks are dried at 300 to 400 deg. F. by loading them on push cars which are very slowly passed through a coal-fired drier. The time required for drying is 30 hr. After drying, the bricks are fired in the kilns for six days. The temperature in the kiln is brought up gradually until the atmosphere in the kiln clears. It is then assumed that the kiln has acquired a substantially uniform temperature throughout and the temperature is increased to about 1900 deg. F. No pyrometers are used in the kilns, as it is found that on account of slight variations in the clay mixtures the temperature can be better controlled by means of test pieces, or small samples of bricks. The heat is held at about 1900 deg. for 24 hr., and the kiln is then allowed to cool gradually. For chemical brick, after the usual firing is finished, everything is shut up tight, and the heat is allowed to "soak" into the brick for four hours. The ordinary building bricks manufactured by this company are said to show an absorption of only 2 per cent by weight, after immersion in water for 24 hours.

There are 29 kilns in all, each 30 ft. in inside diameter, with the walls lined with 9 in. of fire brick and a fire brick roof. The usual life of a kiln is 20 years. The capacity of one kiln is 84,000 bricks. The consumption of coal for firing is 600 to 700 lb. per thousand bricks. The company markets its products all the way from Lexington, Ky., to Jacksonville, Fla., the present selling price being $18 to $22 per thousand, according to quality.

Clinchfield Portland Cement Corporation

The raw materials used by the cement company at Kingsport are: Limestone, obtained from Gate City, Va., about eight miles distant; shale, quarried within a few hundred yards of the cement mill; and sand, obtained from the Watauga River. The following table gives typical analyses of these raw materials, as well as of the finished cement.

TYPICAL ANALYSES

	Gate City Limestone	Shale	Sand	Cement
SiO_2	1.18	58.76	81.20	22.10
Al_2O_3	0.33	22.39	10.10	6.98
Fe_2O_3	0.77	7.91	3.98	3.10
$CaCO_3$	96.46	2.84	.....	.....
$MgCO_3$	1.95	1.43	.....	.....
CaO	.....	.....	0.89	62.62
MgO	.....	.....	.....	1.66
SO_3	.....	.....	.....	1.84
Loss	.....	.....	.....	1.93

The limestone is brought from the quarries in hopper-bottom cars and is dumped over a tipple into a storage pile. From this pile it is drawn on to a conveyor belt operating in an underground tunnel, and is elevated by a bucket elevator to two Hammar mills, manufactured by the Pennsylvania Mills Co., Philadelphia, Pa. Here it is crushed to ½-in. size, and then the crushed limestone is carried back to the blending bins, each of which is provided with an automatic sampler that delivers a sample representative of the bin, as it is filled. The samples are analyzed for calcium carbonate. The blend-

CLINCHFIELD PORTLAND CEMENT CORPORATION

ing bins are in charge of the laboratory, and no limestone can be used until such use is authorized by that department. After the analysis of a sample is completed, the laboratory releases for use the blending bin corresponding to such sample, and adjusts the scale for weighing the shale, in proportion to the percentage of calcium carbonate found in the limestone. The scales used are the Richardson Automatic Scale, made by the Richardson Scale Co., New York.

The shale is quarried by hand, and rolled into the mill by hand, the cars delivering the shale to a pair of crushing rolls, from which the crushed material is carried by belt conveyor to the shale storage bins. From these it is tapped into a belt conveyor and delivered to a rotary drier, fired with coal, 5 ft. in diameter by 40 ft. long. The dried shale then goes by bucket elevator to a bin over the scales.

After the necessary adjustment of the scales, the limestone and shale are weighed, and then the two are mixed, both scales tripping at the same time, discharging the materials into a screw conveyor under the scales. This discharges the mixture of materials to a bucket elevator, which hoists it to a point over the driers. Here the material divides into two directions, and falls into two rotary steel mixture driers, 6 ft. in diameter by 60 ft. long, fired by pulverized coal, which is blown from the kiln room into the mixture driers by a blast of air, through a 4-in. pipe 160 ft. long.

The dried mixture falls into a pan conveyor and goes to the raw grinding department. Here it is carried by bucket elevator to bins above five Hammar mills, two manufactured by the Pennsylvania Mills Co., Philadelphia, and three by the Williams Patent Crusher Pulverizer Co., St. Louis, Mo. In these mills the mixture is reduced to proper fineness for the tube mills, i.e., 80 per cent must pass through a 20-mesh screen. The crushed mixture is elevated by bucket elevator and delivered to a rotary screen, and any oversize is returned to the Hammar mills. The fines pass on to the tube mill bins. The seven tube mills pulverize the screened mixture so that 97 per cent will pass through a 100-mesh screen, and deliver the product to a screw conveyor, which discharges to a bucket elevator, and this to another screw conveyor, overhead, which delivers the dried and pulverized raw mixtures to the kiln boxes, or, if desired, to a silo or storage bin for holding a reserve supply of pulverized mixture sufficient for one day's run.

Cement Kilns

The cement kilns are made of steel plate, lined with fire brick, 9 in. thick at the firing end, tapering to 4 in. at the rear end. There are five of these kilns, each 8 ft. in diameter by 125 ft. long. The pitch of the kilns is $\frac{3}{4}$ in. per ft. The speed or rotation varies from $\frac{1}{2}$ of a revolution to 1 revolution per minute. The speed is regulated by variable speed motors, operated at the firing end. The kilns are fired with pulverized coal, whose fineness is such that 96 per cent will pass through a 100-mesh screen.

The coal pulverizing equipment consists of four mills, manufactured by the Raymond Bros. Impact Pulverizer Co., Chicago, and two Ruggles-Coles driers. Each kiln is equipped with an independent blower unit, manufactured by the American Blower Co., Detroit, Mich. The amount of coal fed to the kilns is regulated by cone pulleys. From the kiln box the pulverized mixture drops into a screw conveyor, and then into a second screw conveyor below the first, for regulating the speed of delivery to the kiln. The material is fed into the kiln dry. The temperature in the kiln is about 2500 deg. F.

The clinker falls into pits beneath the kilns, is hoisted by bucket elevator and delivered to rotary coolers. There are two of these, one taking the output of two kilns and the other the output of three kilns. The coolers are old bottle-shaped kilns, 60 ft. long, varying in diameter from 4 to 7 ft. In each cooler there are four angle irons, which help to tumble the clinker about inside the revolving cooler.

From the coolers the clinker is discharged to a bucket elevator, and thence conveyed by pan conveyor to the clinker storage pile, which is exposed to the weather. This has two underground tunnels beneath it, provided with belt conveyors. The clinker is tapped through holes, at any desired point in the storage pile, and is carried back to the finishing mill.

Here there are two rotary driers, in which the clinker is dried, elevated, and dropped into a scale, which weighs 20 bbl. at a time. At the scale, $3\frac{1}{2}$ per cent of crushed gypsum is introduced. The scale dumps into a pit, from which the dried clinker is elevated by bucket elevator to an overhead pan conveyor, delivering to the Griffin mill boxes.

There are ten Giant Griffin mills (40 in.) made by the Bradley Pulverizer Co., Allentown, Pa. In these the dried clinker is ground so that 100 per cent will go through a 20-mesh screen. The ground material then goes through four Allis-Chalmers tube mills, where it is pulverized to standard specifications, which are, usually, that 80 per cent must pass through a 200-mesh screen. The pulverized cement is elevated to a screw conveyor, which carries it to 24 bins, 12 in each of two stock houses, the capacity of each bin being 4000 bbl. In the stock houses the cement is drawn from the bins into screw conveyors running transversely, and delivering into a central conveyor which feeds the six Bates automatic packing machines, manufactured by the Western Valve Bag Co. of Chicago. After packing in bags, the cement is trucked to cars for shipment. The capacity of the plant, running 24 hr. per day, 12 hr. per shift, is 2500 bbl. of cement daily.

Cottrell Precipitator

The Clinchfield Portland Cement Corporation has just completed the installation of a complete Cottrell precipitating plant, comprising both a dry treater and a wet treater, for precipitating the dust from the cement kilns, with the twofold object of recovering potash and eliminating a nuisance. A steel flue 9 ft. wide by 14 ft. deep, provided with hopper bottoms and screw conveyor beneath, conveys the gases from the kiln to the dry treater. This flue, and also the stacks which permit the gases to escape into the atmosphere, are provided with dampers, so that the gases may either be allowed to escape or be diverted to the treater at will. A small quantity of dust low in potash may be precipitated in the flue. The flue is 102 ft. long, and on the top of it, to utilize some of the waste heat, there are evaporating pans 9 ft. by 9 ft. by 6 in. deep in the center, for evaporating the solution returned from the wet treater. By means of the screw conveyor underneath the flue, the dust can be returned to the kiln, in case the price of potash should not warrant putting the dust on the market. The portion of the flue nearest the dry treater is provided with a water spray inside, to humidify the gas.

The dry treater, built of steel and brick, consists of four chambers, two on either side of a central combination inlet and outlet flue. This flue in its entirety is rectangular in shape, with a diagonal steel partition extending from the bottom of the inlet end to the top of the outlet end. The top part, above the partition, is the inlet flue, and the bottom part, below the partition, is the outlet flue. The ports for letting the gas into and out of the four treating chambers are provided with dampers. In each chamber the gases pass down through eighty 12-in. iron pipes, each 15 ft. long. In the center of each pipe, from top to bottom, hangs a soft annealed iron wire, No. 14, B. & S. gage, with an iron weight, shaped like the frustum of a cone, weighing about 9 lb., suspended at the bottom. To keep the wires from swinging, and to keep them spaced properly, the wires pass through an iron grid, placed 15 in. below the bottom

COTTRELL PRECIPITATOR AT CEMENT PLANT

of the 12-in. pipes and just above the 9-lb. weights. This grid is made of flat iron strips, 1 in. wide by $\frac{3}{16}$ in. thick. The grid is stiffened at two diagonally opposite corners, by omitting the usual wire from the 12-in. pipes at these corners, passing through each of these two pipes, instead of the wire, a 1¼-in. iron pipe which is firmly fastened at the top, and also to the grid at the bottom.

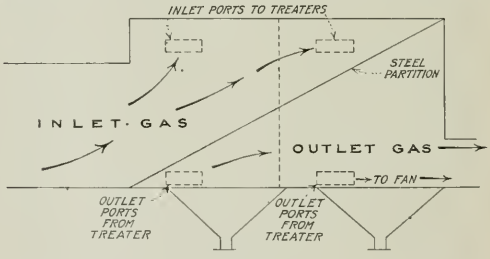
The current is transmitted by means of a ⅜-in. iron pipe connecting with a bus bar made of 5-in. iron pipe. This connects to the various iron wires suspended in the 12-in. pipes. The bus bars are insulated by means of Alberene stone slabs, made at Schuyler, Va. The insulators consist of eleven slabs, six of which are 6 in. by 6 in. by 1 in. thick, and the five others 9 in. by 9 in. by 1 in. thick.

The four treaters discharge the gases into a common outlet flue, which leads to a Buffalo Forge Co. conoidal multiblade fan, with impeller 12 ft. in diameter and speed of 144 r.p.m., and said to be capable of discharging 180,000 cu.ft. of gas per minute.

The dry treater will precipitate only the coarser dust. The very fine dust and the fume will be blown by the fan to the wet treater. The temperature of the gas in the dry treater ranges from 900 to 1100 deg. F. The capacity is 20 tons of dust per day, which is expected to contain about 10 per cent of water-soluble potash (K_2O). The treater will operate continuously, but the dust will be withdrawn from the hopper-bottoms only at intervals, and will be packed for shipment without further treatment. This equipment has already been tested experimentally, and undoubtedly by this time it is in continuous operation.

The wet treater, like the dry treater, has four chambers, but here the chambers are arranged in a single row, with the inlet flue passing along one end of the four chambers. The gas is blown into this flue by the large fan mentioned above, and is admitted to the treater chamber through dampers of the "jug" type, two dampers being provided for each chamber. The gas passes upwardly through the damper openings (about 36 in. in diameter) then turns at right angles to the left and passes into the chamber, which is provided with six vertical concrete partition walls, each 6 in. thick by 10 ft. wide by 14 ft. high, built 15 in. apart. These walls divide the chamber into seven compartments, and in each compartment there are suspended, between the walls, 24 iron wires, No. 14 gage, weighted at the bottom with 30-lb. weights, and connected to one another at the bottom by a grid made of 1¼-in. iron pipe. There are 168 of these wires in all in each chamber. The surfaces of all the walls are covered with flowing water, which is distributed at the top by means of a system of pipes. The gases, after turning to the left, pass through the seven compartments, the fine dust and fume are precipitated by the high tension current with which the 168 wires are charged against the wet walls, and are washed by the flowing water to the bottom, and the gas passes on to the left end of the compartments, and escapes through a damper hole to an outlet flue which connects with all four of the chambers, and leads to a concrete exit stack, 8 ft. in diameter by 18 ft. high.

Power for the treaters is obtained from the Kingsport Utilities Corporation at 440 v., and by means of four motor generators it is changed to 220 v., a.c. single



DRY TREATER

phase, and is then stepped up by transformer to 75,000 v.

The precipitated liquid and dust are collected in a tunnel beneath the treater chambers, and flow to a concrete settling tank 24 ft. in diameter by 12 ft. deep at the deepest part, the bottom being funnel-shaped. The liquid is pumped to the evaporating pans previously described, on top of the gas flue, and is there evaporated. The sludge from the settling tank is filter-pressed, and the cake rejected. The filtrate returns to the settling tank, and is pumped along with the other liquid to the evaporating pans on the flue. The evaporation is not carried to dryness, but at a definite specific gravity the liquid is drawn off into two final evaporating pans 16 ft. long by 8 ft. wide by 3 in. deep, fired with coal, where the evaporation is completed and solid crude potash obtained. The Cottrell plant, as well as the cement mill, was designed and built by Richard K. Meade & Co., Baltimore, Md.

The Clinchfield Portland Cement Corporation also owns and operates a lime-burning plant, located a short distance from the cement mill. It consists of five vertical kilns, built by Richard K. Meade & Co.

Flotation for the Practical Mill Man

A Description of Several Important Factors in Concentration by Flotation — Extraction and Grade of Concentrate — Slime Effects — Pure Water — Time — Oils — Pulp Density — Recleaning Concentrates

By FREDERICK G. MOSES

IT IS a well known fact that the difficulties encountered in flotation plants in different sections of the country are many and varied. While it is true that, in the great majority of mills, the troubles are soon located and remedied, there are many other plants which are not so fortunate in the solution of their problems. It is usually found in the latter case that, although there is nothing apparently wrong with the mill or its operation, the results being obtained are not so good as the experimental work on the ore had led the builders to believe could be obtained. Because a profit is being made, the idea of leaving well enough alone often leads the operators into the state of mind in which they are satisfied to make the best of a bad situation and to be content with the results that they can get.

There are some cases in which the mill results are not satisfactory and, moreover, cannot be readily improved. This is, however, seldom the case. More often the poor results are caused by some condition, often a simple one, that can easily be remedied, if located. Unfortunately, there is such a multiplicity of conditions, any one of which can cause poor flotation results, that it is hopeless for the average mill operator to investigate more than a comparatively few possibilities.

It will be the object of this discussion to suggest some of the factors affecting flotation results, and to suggest ways in which some of them may be overcome. Of course, it will be possible to consider only a limited number of the conditions that work for poor flotation results. There is always the chance, however, that a discussion of some of the more common difficulties encountered in flotation plants will suggest the manner by which some specific or unusual source of trouble can be discovered and eliminated.

Flotation a Concentration Process

It is imperative that the fact that flotation is a concentration process, as much as any gravity scheme, be borne in mind. If this fact is remembered when considering any phase of flotation, the solution of the problems connected with its operation will be considerably simplified.

As flotation is a concentration process, it must follow that the economic laws of concentration will apply to it as much as to the gravity concentrator. In every case of concentration there is a maximum extraction and grade of concentrate possible. This theoretical result can be approached in the commercial installation, but never reached. Usually the greatest obstructions in the way of obtaining scientific results are the economical considerations that surround the mill operator on all sides. The plant must be run to make the greatest profits, and attempts to obtain better metallurgical results will often serve only to reduce the profits.

It must also be borne in mind that, like a table, the capacity of a flotation machine is limited. Notwithstanding the fact that the maximum capacity is but seldom reached, there is always the possibility that this be done, to the detriment of the results obtained on the machines. If the operator takes care that the apparatus is not overloaded, he has eliminated many of the chances for poor work in his plant.

The crushing of flotation feed is as important to good flotation results as the crushing of table feed is important to good table work. The sizes that can be floated are limited to a fewer number than can be tabled successfully, and poor sizing or classification of flotation feed can cause even more unsatisfactory results than in gravity machines. The ore must, of necessity, be crushed fine enough to free the maximum quantity of mineral, but with the production of the minimum amount of slime or very fine material. The slimes, especially the true colloidal material, will be found to be more often the cause of poor flotation than any other factor that will be encountered in the plant.

Extraction and Grade of Concentrate

The metallurgical and economical success of the flotation plant depends on the recovery of the greatest amount of the valuable mineral from the ore in the purest possible concentrate. Just what are the economical limits of extraction and grade of concentrates depends on local conditions and must be determined for each mill; in the present discussion, they will be considered to be the best metallurgical results allowable under the conditions existing in the locality of the mill.

As already suggested, each ore has a maximum and definite ratio of concentration, and hence there is a maximum grade of concentrate possible. The maximum extraction is, of course, 100 per cent of the values in the ore, a figure that can only be approached. The important fact to be remembered in this connection is that in the flotation plant, as in the gravity mill, recovery can be increased only at the expense of grade of concentrate, and vice versa. The flotation operators who remember this fact will save themselves much trouble and worry that always follow attempts made to obtain scientifically impossible results. Unfortunately, so few plants are approaching theoretical results that their consideration can be eliminated from the present discussion.

Flotation Recoveries

Ignoring, for the present, the consideration of grade of concentrate, it can be said that extraction by flotation depends on many factors, among the most important of which are: (1) The physical condition of the ore being treated, (2) the flow sheet of the mill, and (3) the effectiveness of the flotation operation. While the first two are not so important as the last, they are so often the cause of flotation difficulties that they should be considered.

At the present time, the mineral values that occur in

the ore as sulphides are all that can be depended upon to be recovered by flotation. When only non-oxidized sulphides are present, it should be possible, theoretically, to obtain high metallic extractions. However, when such easily oxidized material as iron sulphide is present and carries values, as often happens, trouble in obtaining good recoveries may be encountered. There have been put on record cases in which this material, by simply lying in the ore bins for a short time, has undergone enough oxidization to make the flotation of the iron sulphides very difficult. The remedy, of course, for a condition of this sort is to mill the material as soon as possible after it has been hoisted.

The size of the sulphide particles occurring in the ore greatly affects the possible recovery from an ore. When this sulphide reaches the flotation machines in very coarse sizes it will not float. Unfortunately, on the other hand, when the sulphide particles have been ground too fine, or "slimed," they can be floated only with difficulty. In most cases it will be found that the greatest loss in the tailings from a flotation plant is in the minus 200-mesh material. Proper crushing previous to flotation will correct these conditions to a great extent. However, the actual size and condition of the sulphide, as it occurs in the ore, will be a very dominant factor.

All ores carrying decomposed or kaolinized minerals are difficult to float. This physical condition will probably have more effect on the actual flotation operation and its results than any other single thing that could be mentioned, and at the same time it is the most difficult to overcome. Why clay and other colloidal material have such harmful effects is difficult, at best, to explain on a scientific basis. A discussion of this point will delve so deeply into the pure theory of flotation as to be out of place in this consideration. Instead, a few suggestions about means of eliminating or controlling this material will be more to the point.

There may be said to be two general schemes by which the detrimental effect of slime may be overcome. The first and most important is by flocculation or precipitation by chemical or electrochemical schemes. The second and least used method is that of washing. Heating of the ore before crushing is sometimes tried.

Rather than give a long scientific definition of just what colloidal material is, it will be better to give a very simple method of determining the presence and amount of this material. Colloidal material, or more commonly "slime," can be best detected and its quantity estimated by the slowness with which it will settle in water. A rough application of this scheme can be made by taking a portion of the flotation pulp and shaking it thoroughly in a bottle. If there is any quantity of colloids or slime present the water will remain murky after standing for a few minutes. If this cloudy appearance persists for half an hour there is probably sufficient slime present in the pulp to interfere with flotation.

The amount of the slime that may be present may be roughly estimated by the depth of clear water that appears on top of the pulp in a given time. Of course, this means will only give comparative results, but this is all that would be required except in special cases.

Removal of Slime

Some simple chemical compounds, under certain definite but usually little understood conditions, have the property of causing the suspended or deflocculated slime in the pulp to collect together, or flocculate, changing the physical conditions in such a way that rapid settling occurs. It has been found by experiment that slime in this condition usually has very much less harmful effects on flotation than when deflocculated. Sulphuric acid, lime sodium carbonate, acid sodium sulphate, copper sulphate and many other substances, when used in very small amounts, have the property, under certain conditions, of flocculating the slimes. In this way their harmful effects are very largely removed.

At the present stage of our knowledge of this phase of flotation, it is practically impossible to foretell which of the numerous reagents that have been used for this purpose will give the required results on a particular ore. The most effective one can only be determined by experiment under the conditions under which it is to be used. The reason for this is our lack of knowledge of the real manner in which they act on the slimes in the ore.

The ideal manner of ascertaining the reagent to be used is by direct experimentation in the commercial cells of the operating plant. If, for any reason, this is not feasible, indicative results can sometimes be obtained by a series of tests made in bottles. Several samples of the pulp from the flotation machines, containing the oils being used, are placed in a series of bottles and well shaken. Two or three drops from solutions of the various reagents are then added to the bottles, a separate bottle being used for testing any one solution. The bottles are then placed where they will be free from vibration for an hour or more. It will be seen, at the end of this period, that some of the bottles have a certain volume of clear water above the cloudy pulp and that, in certain cases, this volume will vary widely. It is usually the case that the reagent showing the greatest settling effect will produce the best results when used in the cells. However, this is not always the case.

The removal of slimes or colloids by washing is a more difficult matter, requiring quite an installation of settling tanks or thickeners, and a comparatively large supply of fresh, pure water. This last item is of the utmost importance. The actual operation of the scheme is quite simple. The pulp, before being floated, is settled in the thickening tanks, which are so operated as to give the thickest spigot product possible, without allowing the overflow to carry away an excessive amount of valuable mineral. The overflow, which carries a large portion of the slime material, is allowed to run to waste, and the thick spigot product is diluted with sufficient clean, fresh water to give the correct pulp density for flotation. This method has worked well in several large plants in the West.

Another scheme which might be used, but which for various practical and economical drawbacks has received but scant attention, involves heating the ore before crushing to a temperature great enough to put the slime-forming material in the ore into such a physical condition that slime formation is retarded when the ore is wetted and crushed.

There are many materials foreign to the ore, such as decomposed vegetable matter, lubricating oils from line shafts or crusher bearings, soap, sewage, grease from mine-car wheels, etc., that will interfere greatly with flotation. The only sensible remedy for this type of trouble is to eliminate the source of it. Great care must be taken to prevent these substances from getting into the flotation feed. The great difficulty often encountered

in finding the source of this sort of interference makes it imperative that care be used to eliminate it.

Mill Flowsheets and Their Effects

Sometimes it does not seem possible that such a simple matter as the location of a table in a flotation mill could make any great difference in the results obtained. Nevertheless this has often been proved to be the case.

It is as necessary that the flowsheet of a plant using flotation be as carefully worked out by experiment as when gravity processes only are to be used. Many flotation plants can be shown to be doing unsatisfactory work for this reason alone.

In many instances, the ore should be tabled previous to flotation in order to remove the heavy sulphides which are present but which cannot be floated. These will only tend to build up in the machines, choking up the cells and preventing their efficient operation. Also, it is sometimes possible so to remove from the pulp certain deleterious substances, such as slimes.

In certain cases the best results demand that the pulp be tabled after flotation. A great tendency in many flotation plants is to carry too dilute pulp in the flotation apparatus. Tabling before flotation is bound to add water to the flotation feed and this causes poor operation. Tabling following flotation has not this drawback.

The use of pilots by which the work of the flotation machines can be judged should not be overlooked in this connection. The flotation operators can soon be taught from the appearance of the tables treating the flotation tailings whether the cells are doing good, bad or indifferent work. They thus have an optical demonstration of what their part of the general scheme is accomplishing, and this will always work toward securing better results from the flotation machines.

Before leaving the discussion of mill flowsheets and their bearing on flotation results, the effects of various types of crushing on flotation results should be mentioned. This is one of the things that is without the pale of help from the operator, but some valuable suggestions may be evidenced by the consideration.

There is no doubt that the type of crushing to which the ore has been subjected before flotation will have a noticeable effect on the results obtained. The well-known case of the Inspiration mill, where a better result was obtained by crushing with iron on iron than by pebbles on iron, is an example of what a difference such a simple point can make.

The fact that the type of crushing which produces a large amount of slime is not as satisfactory as that which will produce the minimum quantity has been already suggested. A certain plant in Arizona is divided into two units, exactly alike, except for different types of crushing machines employed in them. The ore, flotation equipment and other factors are the same. The extractions obtained in the two units always varied to a certain extent, and the difference in the crushing was the only explanation that could be offered as the reason for this peculiar behavior.

Flotation has a definite field in saving that portion of the sulphide content of an ore that is too fine for satisfactory gravity work. It can never be made to replace tables satisfactorily, except under an unusual combination of circumstances. Stage crushing, therefore, with the removal of the mineral as soon as it is freed, followed by flotation of the sulphides that have been crushed too finely for table work, in general seems to be the best and most logical scheme, and should be followed whenever possible.

Effectiveness of Flotation Operation

The points already discussed have been mentioned because of their indirect effect on flotation. There are, also, certain factors in the operation of the flotation equipment itself that are of even more importance to good flotation results than those already mentioned.

One of the most important factors in good flotation is the oils or combination of oils that are being used. If all of the other conditions are perfect with the exception of the oil, good flotation results are impossible. Unfortunately, the investigation of oils covers such a large field and depends on so many little understood or unknown factors, that no definite rules for determining the most satisfactory oil can be given.

As long as the art of flotation has been practiced, the only feasible method of determining the oil best adapted for an ore has been by laboratory or mill experiments. This method of investigation involves much time, patience and money, but the importance of the information gained always justifies the expenditure. The operator should never reach the state of mind that permits him to be satisfied with the oil he is employing. He should test all of the logical mixtures available, and as new oils come on the market, they should, also, be given their chance.

The agitation to which the oil and pulp have been subjected is the next important factor in good flotation results. This must be correct, both with regard to kind and amount. The lack of sufficient agitation is usually evident at once, but too much is more difficult to recognize and is just as harmful as the opposite state of affairs.

Too much agitation will do one of two things: either produce too much froth, usually of an unsatisfactory character, or cause the oils to be so thoroughly emulsified as to destroy much of their flotation value. It is very probable that the principal function of much of the acid used in flotation is to throw oils out of emulsion that have received too much agitation in the ore pulp.

If the mechanical agitator type of machine is not designed correctly for the ore which it is to treat, it will either produce too much froth or too little. Either of these conditions will tend to cause poor recovery. When the ratio of the size of the agitator and its speed is correct, or that of the agitator compartment to the froth tank or spitzkasten, the quantity of froth produced by the use of the right amount of oil will be wrong. In such a case, the common method of attempting to rectify conditions is by changing the amount of oil used. This is unsatisfactory in most cases.

If too little froth is being made by the machine by the use of the correct amount of oil, air blown into the pulp at the bottom of the spitzkasten will often correct matters very satisfactorily.

The troubles caused by the production of too much froth when the correct amount of oil is being used are much more difficult to rectify. The greatest chance for improvement, under these conditions, is to increase the tonnage to the machine, although other factors may cause this scheme to fail.

Over-oiling the flotation pulp will usually be indicated by the occurrence of large amounts of mineral-bearing

froth in the launders carrying the tailings from the machines, or on the tables or other apparatus that may be used to re-treat the flotation tailings.

Importance of Pure Water

One of the greatest necessities for good flotation work is a large and constant supply of fresh and pure water. It is considered good flotation practice to settle the water from the flotation tailings for re-use in the flotation circuit, in order to obtain the benefit of the oils that will be returned to the mill in this manner. This is logical and works very well, within certain limits. A point that must at the same time be considered is that the soluble constituents of the ore or oils will gradually be concentrated in this return water, and will eventually attain an accumulation that will interfere very materially with the operation of the flotation machines. For this reason, increasing the amount of fresh water that is being added to the flotation circuit will often work wonders in the way of improving flotation results. This fact is very easily determined and the test should be made at frequent and regular intervals.

Often the fresh water supply of the mill will carry certain unsuspected impurities in solution. These impurities may be either harmful or beneficial. The preponderance of chances are, however, that they will interfere with the proper operation of the cells. Fortunately, most of the inorganic salts that occur in this way can be very easily and cheaply removed by simple chemical precipitation. Many cases have been known where the flotation plant had been built on the strength of a large amount of successful experimental work, but no successful results could be obtained until by chemical analysis of the water used in the mill circuits the presence of large amounts of inorganic salts in solution had been demonstrated. When this material had been removed by the use of lime or some other necessary reagent the mill at once commenced to produce the results that had been expected when the plant was completed.

Organic material, such as soaps, glues, decomposed vegetable matter, organic soil constituents, etc., will cause more harm in the flotation plant than the inorganic salts just mentioned. Their removal is a much more difficult proposition. If their presence can be proved to be the cause of trouble, it would be better to employ special talent to handle the situation rather than to allow inexperienced men to try their hand.

Time Factor and Flotation Results

The period of time during which the ore pulp is under treatment in a flotation machine is a most important factor of good flotation results. Flotation is by no means an instantaneous process. A certain definite time is required to remove the concentrate from the ore pulp. The amount of time required for this purpose depends on several important considerations, among which may be mentioned (1) the amount of pulp, in gallons, which is being treated in the flotation apparatus per minute, (2) the solid content of the pulp volume being treated, (3) the number of pounds of concentrate that must be removed from each gallon of the pulp, (4) the strength or carrying power of the froth being made on the machine, and (5) the quantity of froth being made per unit time.

It will be evident that, other things being equal, the more dilute the pulp the greater will be the velocity with which each unit of ore in the pulp will pass through the machine. Hence, to obtain the same time of treatment on the more dilute pulp will require a greater comparative length of time of treatment in the machine. When dealing with pulp dilution, however, many other factors enter into consideration and the above can only be taken as a generality.

On the other hand, a pulp must not be too dense, or the bubbles cannot rise freely to the surface. When the pulp is too dense there is the added chance that the bubbles will be scoured clean of their mineral load. The correct pulp density to fit the conditions of the case can only be determined definitely under practical operating conditions.

A froth has a certain maximum carrying power. When it is made at a definite rate per minute it can lift only a certain limited amount of concentrate. If more pounds of concentrate are contained in the pulp fed to the machine than can be removed by this froth, poor extraction of the sulphide in the ore is bound to result. When the poor recovery in the flotation machines can be definitely laid to this condition, the remedy is either to feed a smaller volume of pulp to the apparatus, to make more froth of the same character or, by means of different oils, to increase the carrying power of the froth being produced. The most satisfactory method of remedying the difficulty must depend on the ore and the other local conditions existing in the plant. These points are all matters of experiment and skill of operation.

Relation of Grade of Concentrate to Extraction

In all ore-dressing and concentration processes, the grade of concentrate produced has a most important relation to the possible extraction. A few of the more important reasons why this is especially true in flotation will be mentioned.

An observation of the froth forming on the top of the pulp in a flotation machine will clearly show that a great deal of the concentration that takes place in the machines takes place in the froth. The froth nearest to the pulp will be practically the color of the pulp, but the closer the top the froth is observed, the more nearly its color approaches that of the pure mineral that is being floated.

This effect is caused by a mechanical action that goes on within the body of the froth itself. The bubbles seem to have only a comparatively weak selective action on the sulphides in the pulp itself. This condition causes the froth, first released at the bottom of the froth column, to carry a very large amount of gangue material. As soon as the froth is out of the water, however, it commences to break up, the bubbles first formed breaking up to re-form a slightly fewer number of new bubbles. During this process of re-formation, the sulphides are caught on the newer bubbles formed, while the gangue is, to a large extent, forced to drop back into the pulp owing to the decreased froth surface. This action goes on from the bottom to the top of the froth column, causing the froth the greatest distance from the pulp itself to be the highest in grade.

It can be seen from this that the deeper the froth column carried on top of the pulp in the flotation machine, the higher is the grade of concentrates produced and the greater is the amount of gangue dropped from the froth into the pulp, at the same time, however, the greater is the chance for the sulphide particles to be

dropped into the pulp and lost in the tailings, causing a lowered extraction.

This shows the reason for the relation between the grade of concentrate produced and the extraction possible, and, also, the principal reason for the use of one set of machines for producing the best tailing possible, and the use of another set of apparatus for recleaning the froth produced on the first machines.

Producing Clean Concentrates

At the first of this discussion, the fact was mentioned that, in order for a plant to be successful from both a metallurgic and an economic standpoint, a good extraction of the values in the ore must be obtained, and a high grade concentrate must be produced.

The concentrate is the material that must be sold to produce the income from the milling operation. The greater the amount of valuable metal present, the more can be obtained for it, while the smaller the amount of impurities present, the fewer the penalties imposed by the buyer and the less charged for their treatment. All these considerations make it imperative to produce the highest grade concentrate economically possible.

The grade of flotation concentrates produced will depend on several factors, among which can be mentioned (1) the natural amenability of the ore to the process, (2) the simplicity of the sulphide content of the ore being treated, (3) the sort of results that the flotation equipment is being operated to obtain, and (4) the skill and care with which cleaning the concentrates is done.

The first two of these factors are, to a great extent, beyond the control of the operators. However, the second two are of such a nature that they can be much influenced and controlled by the operators.

Natural Amenability of Ore to Flotation

It has been often found that two ores, apparently of the same physical and chemical makeup, respond very differently to flotation, the one giving maximum results without trouble, while the other can only be treated satisfactorily with the greatest difficulty. Just why this is true is often very difficult to explain.

It is, however, usually easy to obtain both high grade concentrates and high extractions when treating the ores that respond easily to flotation, the probable reason being that when dealing with this type of ores, a small amount of the lighter oils will give high recoveries of the sulphides present, and, at the same time, this type of oiling will in nearly all cases produce the richest concentrates.

When dealing with the other ores—those which can only be made to respond to flotation treatment with difficulty—it is usually necessary, in order to obtain high recoveries of the sulphides, to use a comparatively large amount of heavy flotation oils. This class of oils will, it is true, make high recoveries, but in so doing often float such large amounts of gangue as always to cause the concentrate to be low grade.

As suggested, these factors usually depend more on the ore itself than on any of the conditions that can be controlled. However, from the above it can be seen that when the ore is readily amenable to flotation, both high recoveries and rich concentrates can be produced by the same operation, but when the ore does not respond readily, high recoveries can be obtained with greater ease than high grade concentrates, and neither can be gotten at the same time.

In an ore composed of simple gangue minerals and only one floatable mineral, it is easy to see that the chance of producing high grade concentrate is greater than when two or more minerals that float are present.

Complexity of Sulphides and Grade

When several sulphides, such as lead, zinc and iron sulphide, for instance, are present in the ore, there are two possible schemes that might be used in overcoming the tendency for the production of, say, a low grade zinc concentrate. The success of either of these will depend largely on the character of the ore and its sulphide constituents. One of these methods involves the removal of one or more of the sulphides by gravity before the flotation of the ore for the recovery of the other sulphide. The other scheme depends on a differential or selective flotation operation to recover one of the sulphides without removing the other two. This has been done to a limited extent in various sections of the country, but at best it is a very delicate operation and will require large amounts of experimental work, careful control of the flotation operations themselves, knowledge of the relations of the various minerals to one another and, above all, great skill in the actual operation of the equipment.

There is no question that the grade of the flotation concentrates can be influenced greatly by some such schemes as those mentioned, but their success is bound to be limited. They are really special cases of flotation and should not be discussed here.

Flotation Operation and Grade of Concentrates

Probably the greatest factor affecting the grade of the product is the manner in which the machines themselves are run from shift to shift. The grade of the concentrates will depend largely on (1) whether the machines are being operated to obtain the maximum recovery or the maximum grade of product, (2) on the skill and intelligence with which the oils are used, (3) on the skill and care with which the pulp level and depth of froth on the machines are controlled, and (4) on the pulp density.

The effect of the first point mentioned, the results that are being striven for on the machines, has been suggested already. Much of the concentration takes place in the froth column, and when the froth is allowed to discharge from the apparatus so slowly that most of the gangue has had time to drop from it, some of the mineral will also be dropped into the cells, causing a lowering in the recovery, but at the same time the maximum grade of product will result. Just the point at which these two conditions should be balanced is an economic matter and can only be worked out on the profit sheet of the mill.

The fact should be emphasized at this point that beyond a certain point the grade of concentrate can only be better at the expense of recovery, and vice versa. This will be the dominating thought that will be carried through any discussion involving extractions and grade of concentrates by flotation processes, or any other process, for that matter.

Oil and Grade of Concentrates

The necessity for the intelligent use of flotation oils and reagents to obtain the highest grade of product from a flotation machine has also been suggested in another connection, and should be fairly evident. The strength and carrying power of the froth will depend

largely on the kind and amount of oil used in the circuit. The grade of the concentrate also depends very largely on the same factors. If a weak froth can be made which will carry sufficient sulphide to give a high recovery, this froth, from its very nature, will not be prone to carry much of the gangue.

If a froth of a strong, stiff character is required to give high extractions, it will tend to carry much more gangue material and hence produce a lower grade of concentrate. As the oils are the dominating factor on which the strength and carrying power of the froth depend, the evident relation of the oils to the mineral purity of the concentrate should be clear.

Of course, the ideal practical condition will be to use the oil mixture that will prevent the flotation of the gangue to the greatest extent, and yet float all of the sulphides present in the machine. Under this condition the highest recovery will be possible, and the concentrate produced will be ideal for cleaning in the cleaner cells.

Pulp Level or Depth of Froth

The relation of the level of the pulp and the depth of froth to the grade of the concentrates was suggested in connection with the remarks on extraction. Slowly discharging froth and deep pulp level mean a long period of time for the concentration in the froth column to take place, with the dropping out of a correspondingly large amount of impurities from the froth.

The operators can soon learn, under the different conditions that will be encountered, the correct depth of pulp to obtain the highest extraction and, at the same time, the maximum grade of concentrates. The pulp level will depend to a certain extent also on the quality of sulphides in the pulp fed to the machine.

As a general rule, the larger the amount of sulphide that must be removed from the machine, the higher the pulp level will be carried, and the faster the froth will be discharged. The operators soon learn to judge these conditions, and make the necessary adjustments when they are required.

Pulp Density and Grade of Concentrates

The reasons for the variations in the pulp density upon the grade of concentrates are a little more difficult to understand. The ratio water to solid in a flotation machine has much to do with the character of the froth the machine is producing. Just why this should be true is hard to say.

It has been previously shown that the character of the froth affects the grade of concentrate. Now froth characteristics will continue to have the same effect on the purity of the concentrate, regardless of whether they can be traced to under- or over-oiling of the pulp, or by thickening or diluting it, as in the case now under discussion.

There is yet another manner in which the pulp density may affect the purity of the concentrate. It is the effect of the pulp density on the amount of sulphide that will be carried into the machine in a certain time.

A flotation machine can produce a given amount of froth of certain characteristics in a given period of time. If a dilute pulp is being fed to the machine, there will be fewer pounds of sulphide to be removed by this amount of froth; a condition that, due to its unsaturated condition, will increase the chances of the froth picking up the gangue material, and therefore lowering the purity of the concentrates.

As would be expected, increasing the pulp density will tend to have the opposite effect on the grade of concentrates. In this case, there is an increase in the amount of mineral to be floated by the available froth, causing it to become quickly saturated with sulphide and so leaving but little space for the gangue material. This result is probably brought about by the fact that the sulphides are the easiest to float and will have the greatest tendency to be attracted to the froth and held there, in preference to the non-sulphide material. This condition in the machine will also tend to increase the concentrate grade, but at the same time lower the extraction.

Recleaning Flotation Concentrates

The practice of refloating concentrates produced on rougher cells as a means of increasing their purity is nearly universal at the present time. A short consideration of some of the factors influencing the results obtained by this practice will be of interest.

Successful recleaning of the flotation concentrates in cleaner machines involves several factors: (1) The general idea of all concentration that the grade of the product from a concentrating machine will be higher the richer the feed to the apparatus, (2) the fact that gangue material in flotation concentrate can be eliminated by re-forming the froth under more quiet conditions than those under which it was first produced, (3) making the amount of froth smaller in proportion to the amount of mineral to be lifted, tending to give concentrates of the highest possible grade.

If these facts are true, and they are generally assumed to be so, we can say that the effectiveness of the recleaning or reflotation operation will depend on the following: (1) The ratio between the capacity of the cleaner cells and the amount of the concentrate to be refloated, (2) the purity of the first concentrate produced for recleaning, (3) the skill used in the operation of the recleaning machines, (4) the extraction obtained in the cleaner machines, and (5) the water dilution of the froth being re-treated.

Before proceeding to discuss these points, one fact should be emphasized that is usually assumed to be true but is seldom mentioned: Nearly all minerals have the property of adhering to flotation froth but, of course, in widely differing degrees. An extreme illustration would be the case of limestone and galena. They have both been made to float, and their commercial separation by means of flotation depends only on the degree with which one floats in preference to the other under given conditions.

On this assumption, it follows that when several minerals are present, the most readily floatable will be the first attracted to and carried by the froth, and when the froth has picked up all of the mineral possible and there is still remaining space available this space will then be filled by the next most easily floatable mineral in the pulp, and so on.

With these facts in mind, it should be quite simple to see the importance of having the cleaner cells of a correct size to produce the correct amount of froth to take care of the mineral that is coming to them in the rougher concentrate. As already mentioned, the amount of froth produced on a flotation machine in a given time is a definite and limited quantity. The amount of froth produced, therefore, should be just sufficient to carry the amount of pure mineral that will come to it

from the rougher cells and no more. As the quantity of froth produced will depend on the size of the froth discharge area, other things being equal, the necessity of having the correctly proportioned cleaners should be clear. Practice has shown the above to be true. Several illustrations could be shown where the grade of the final concentrate has been very materially improved by simply decreasing the number of cleaners that were being used.

It follows that the number of cleaner machines in a mill does not depend on the number of rougher machines in the plant but on the number of pounds of concentrate that each rougher produces in a given time.

The effect of grade of feed and its relation to the purity of the cleaner concentrate should be easily seen, especially in view of what has just been said. The higher the grade of the feed to the cleaners, the less are the impurities that are to be eliminated from it, and the less is the work the cleaners will be called upon to do. Usually the grade of the concentrate that is produced for recleaning is determined by the extraction to be made on the roughers, which in turn is determined by economic conditions. This factor is, therefore, to a large extent outside of the control of the operator, except in the more limited sense.

The skill of the operator will probably be shown to a greater extent in the operation of the cleaner cells than in any other manner. He must be taught to run the machines so that just the correct amount of froth will be made and discharged to carry out of the machines the pure mineral that is coming to it, and no more. This can only be done by thoroughly understanding what the machines are expected to do, and closely observing their action from day to day.

It should not be necessary to emphasize the fact that cleaner cells must make the highest extraction possible, consistent with making the necessary grade of concentrate. An excessive loss at this stage of the process only means an excessive quantity of mineral to be returned to the roughers in cleaner tailings, salting the circuit and placing an added load on the roughers, with the increased chance that some of the mineral will be lost in the final tailings, giving an excessively low extraction for the complete operation.

At the same time, it has been shown that grade of concentrate can only be increased by a certain loss in extraction. It is, of course, necessary that the cleaners be so operated that a sufficiently high grade of concentrate is produced. A comparatively poor extraction will therefore be made in the cleaners. Economic considerations will govern this phase of the operation of the cleaner cells. It is common practice, and also logical under many conditions, to operate the cleaners to produce the highest grade of concentrate possible to be made when producing at the same time cleaner tailings equal in valuable mineral to the original rougher feed. This is not always possible, however, and must be governed by other conditions to a great extent.

The last point in the operation of the cleaners is the dilution of the concentrate being cleaned on them. This again brings us to the consideration of the relation of the quantity of froth and the amount of mineral to be saved. The quantity of mineral going to the cleaners should be so regulated that the amount of mineral going to the machine is just sufficient to load the froth. The point that should be watched is to have the pulp dense enough so the mineral actually in the feed will do this. When this is not the condition, it can often be remedied by making less froth on the cleaners or by using less oil on the roughers, causing them to make a froth containing less water. Another remedy would be to reduce the number of cleaners. The desired extraction usually limits the use of these remedies.

When the pulp in the cleaners is too thick and water is needed, only fresh, pure water should be used; under no conditions should return water carrying flotation oil be employed. Return water will carry enough oil to increase the cleaner froth and aggravate the conditions it is used to rectify. The cleaner, to produce concentrate of the maximum purity, should be rather underthan over-oiled.

Conclusions

Several possible sources of unsatisfactory results in the flotation plant have been suggested with possible means for remedying them. In many cases, however, it will be found that the employment of these suggestions will not improve results as had been expected. In most cases, this will not be surprising. When the innumerable factors that can influence flotation results are remembered, it is little wonder that the varying of one or even two of them will make no evident improvement in results. It is only by long contact with the problem, and the understanding of all the various factors and their inter-relations, that the hoped for results are obtained.

Many operators, in striving for perfect metallurgical results, lose sight of the economic side of the situation. Unfortunately, very often, especially in flotation, the correction of or the improvement in one step of the process will only be to the detriment of some other step. This fact must always be borne in mind. When in doubt as to whether the apparent benefits derived from the improvement of some point in the operation are really justifiable, the profit sheet, the true standard of success of all technical operations, should be appealed to for guidance.

Salt Lake City.

Detecting Overheated Bearings

Certain double iodides of mercury with other metals are dimorphic and exhibit a more or less pronounced color change at the transition point. H. T. Pinnock[1] has made a study of these in order to determine which compounds are most suitable for use as visible indicators of overheating in bearings and machinery.

The double iodide of silver and mercury, $AgI.HgI_2$, is a pale lemon yellow powder at ordinary temperatures, but changes to a vivid carmine at 90 to 100 deg. C., the change in both directions being fairly sharp. With copper mercuric iodide, $Cu_2I_2.2HgI_2$, the change from a vivid scarlet vermillion to a chocolate brown takes place at 60 to 70 deg. C. It was found that a mixture of the two, consisting of 85 per cent of the copper salt and 15 per cent of the silver salt, was more sensitive and gave an exceedingly sharp transition from vermillion to almost black at 60 to 70 deg. C.

For application to bearings, etc., these compounds are mixed with white shellac spirit varnish or, for more elevated temperatures, a medium such as is used in aluminium paints for steam pipes, in the proportion of 100 g. compound to 70 cc. of medium. This paint is best applied as a bullseye or band on a zinc white background. After the paint is dry, it should be protected with a coat of colorless oilproof varnish.

The Art of Searching Chemical Literature

By Harold Hibbert

THERE is no more important phase of research or technical work in chemistry than that indicated by the above title. Thus, whether the chemist is concerned with the acquirement of a comprehensive knowledge of the properties of any particular compound for research or technical purposes, or again with matters relating to patent and other litigation, the ability to search the literature rapidly, thoroughly and efficiently is of prime importance, and no less important is the saving of time and money in preventing the "new" discoveries of old facts.

In the first place, in order that the chemist may be thoroughly equipped to carry out an investigation of the chemical literature, it is necessary that he should be able to read both French and German readily, and if he possesses a nodding acquaintance with Russian and Italian so much the better.

It is difficult not to be impatient with the foolishness shown in the outcry against the teaching of German in the public schools and colleges, since no matter what our present feelings may be with regard to the German nation, the fact remains that a very large proportion of our chemical knowledge and scientific facts are only to be found to-day in German periodicals, special treatises and text-books, so that it is imperative on the part of the future chemist to acquire a good thorough knowledge of this language.

In this article the question of conducting a search of the chemical literature will be dealt with more from the point of view of the technical chemist than from that of the university student. At certain schools of chemistry such as the Universities of Illinois and Pittsburgh, it is understood that special courses of from six to eight lectures are given on this subject, and in connection therewith, actual practical work carried out relating to literature research and abstracting.

It would be an admirable thing if this scheme could be extended to all of our leading colleges and the full lecture course published in book form for the benefit of chemists in general.

The method of conducting a search of chemical literature will vary depending on whether the product to be investigated is of organic, biochemical, inorganic or mineral origin, and the question of the method to be adopted in the case of organic derivatives will be first discussed.

The Search of Organic Chemical Literature

With regard to this field, if it is only desired to ascertain from the analysis of a certain new product whether its properties correspond to those of some substance already known, the matter is much simpler than where we are concerned with the desire to ascertain whether the product in question has been either (*a*) made previously by any method, or (*b*) made previously by a specified method, or (*c*) where we desire information regarding the chemical behavior of the compound.

Scheme 1. If the chemist is merely concerned with the properties and identification, it is sufficient for him to determine first of all its empirical composition and then by reference to Richter's Lexikon der Kohlenstoffverbindungen 1910-1912 or better, the Stelzner Literatur-Register der Organischen Chemie 1910-11, in case the derivative is to be found in the latter, to obtain the corresponding reference to the product in Beilstein's Organische Chemie, from which, by perusing both the original and supplementary volumes, the desired information can in general be obtained. If the physical properties such as specific gravity, refractive index, melting-point, boiling-point, etc., are not given, they can very frequently be obtained by referring to the journals in which the various researches on the subject are published.

In many cases, as regards the physical and chemical properties of the derivatives, much time may frequently be saved by referring in the first instance to well known reference books such as:

(a) 1. Kaye and Laby—Tables of Physical and Chemical Constants (1918).
2. Liddell—Metallurgists' and Chemists' Handbook (1916).
3. Chemical Rubber Co.—Handbook of Chemistry and Physics (1919).
4. Van Nostrand's Chemical Annual.
5. Landolt-Bornstein Phys. Chem. Tabellen.
6. Mullikin—Identification of Organic Compounds (1911-1916).
7. Rosenthaler—Der Nachweis organischer Verbindungen (1914).
8. Biedermann—Chemiker Kalendar (1916).
9. Seidell—Solubilities of Inorganic and Organic Substances (1911).
10. Comey—Dictionary of Chemical Solubilities (1896). (New edition in the press.)
11. Tables—Annuelles (1912-1914).
12. Fowle—Smithsonian Physical Tables.

Scheme 2. On the other hand, the chemist may wish to ascertain the best method for making a specified organic derivative. In this case he should first follow the method outlined under Scheme 1, and then from the references given consult the original literature.

In addition to this, he should review the decennial indexes (author and subject) of

(b) 1. Chemical Abstracts (Amer. Chem. Soc., 1907 —).
2. Chemisches Centralblatt (1830 —).
3. Berichte der deutschen chemischen Gesellschaft (1868 —).

as well as the following text-books and encyclopædias:

(c) 1. Meyer - Jacobson — Lehrbuch der organischen Chemie (1907).
2. Richter—Chemie der Kohlenstoffverbindungen (1894).
3. Bender-Erdmann—Chemische Präparatenkunde (1893-1894).
4. Schmidt—Ausführliches Lehrbuch der pharmazeutischen Chemie (1910).

(d) 1. Ullmann—Enzyklopaedie der technischen Chemie (2 vols.), 1914-1915.
2. Molinari—Treatise on general and industrial organic chemistry (2 vols., trans. Pope, 1912-1913).
3. Vanino—Handbuch der präparativen Chemie (1914).
4. Thorpe—Dictionary of Chemistry (5 vols., 1912-1913).
5. Watts—Dictionary of Chemistry (4 vols., 1911-1914).
6. Ure—Dictionary of Arts, Manufactures and Mines (4 vols., 1867-1878).
7. Dammer—Chemische Technologie der Neuzeit (3 vols., 1910-1911).
8. Blücher—Auskunftsbuch für die chemische Industrie (8th Ed., 1913).
9. Sadtler—Industrial Organic Chemistry (4th Ed., 1912).

(e) 1. Weyl—Die Methoden der organischen Chemie (2 vols., 1911).
2. Lassar-Cohn—Arbeitsmethoden (4th Ed., 1907).

If the chemist desires to manufacture a product by some scientific process involving purity of material

rather than a consideration of yield, the methods referred to in the literature under (*b*) will probably best answer his purpose.

On the other hand if he wishes to ascertain the best method for producing a product commercially, that is, under conditions where the yield is probably more important than scientific purity, more detailed information is likely to be found in the literature quoted under (*d*) and (*e*).

The two volumes quoted under (*e*) are very valuable from the point of view of giving the research and technical chemist important information as to the various devices and schemes incidental to oxidation, reduction, hydrogenation, chlorination, etc., which have been found useful in overcoming the experimental difficulties relating to the synthesis of a wide variety of organic derivatives. Very frequently by referring to the index for the particular derivative in question (or failing this, the next lowest or related member of the series) the desired information can at once be obtained.

In this connection it is felt that where important processes are published in scientific journals, difficult for the average man to read or translate, the American Chemical Society should give even fuller abstracts so that it would be possible to repeat the work without having to consult the original. These remarks are made with special reference to the valuable scientific data published by the Russian Chemical Society.

Scheme 3. It frequently happens that the chemist is called upon to make a thorough search of the literature either for the purpose of obtaining a complete knowledge of the subject or for patent or other purposes of litigation, and in this case a more careful and elaborate study is necessary.

In the first place much of the earliest information, modes of preparation, and properties of organic derivatives are not to be found in Beilstein, so that at the outset a thorough search should be made through volumes such as:

(*f*) 1. Erlenmeyer—Handwörterbuch der Chemie.
2. Fehling—Handwörterbuch der Chemie (8 vols., 1871-1913).
3. Kolbe—Ausführliches Lehr- und Handbuch der organischen Chemie (3 vols., 1880).
4. Muspratt—Chemistry as Applied to Arts and Manufactures (2 vols., 1860).
5. Muspratt—Theoretische praktische u. analytische Chemie (10 vols., 1886 —).

Having gone carefully through these treatises, he is then ready to study the original and supplementary volumes of Beilstein, as a result of which the literature relating to the particular derivative in question, as well as to its closely related analogues, should have been carefully abstracted.

The latter procedure is of importance, since it often happens that valuable information, while not disclosed in the literature relating to a given product, is frequently quoted in a description of a closely related derivative. Thus a process for reducing nitroxylene might not be found, let us say, under xylidine, but might be found by studying the preparation and properties of the corresponding toluidine.

In general the next procedure would be to go carefully through the yearly indexes of list (*b*), which, though somewhat laborious, enables a thorough search to be made. If as a result of this review a still more thorough and complete one is deemed necessary, the following journals should then be carefully abstracted:

(*g*) 1. Dingler—Polytechnisches Journal (1820 —).
2. Wagner-Fischer—Jahresbericht (1855 —).
3. Kopp-Fittica—Jahresbericht über die Fortschritte der Chemie (1847 —).
4. Biedermann—Technisches Chemisches Jahrbuch.

(*h*) 1. Meyer—Jahrbuch der Chemie (1891 —).
2. Chemisches Centralblatt (1830 —).
3. Journal of American Chemical Society, Abstracts (1907 to date).
4. Journal of Chemical Society, London, Transactions and Abstracts (1849 —).
5. Comptes Rendus (1835 —).
6. Bulletin de la société chimique (1861 —).
7. Liebig—Annalen der Chemie (1832 —).
8. Berichte der deutschen chemischen Gesellschaft (1868 —).
9. Journal für praktische Chemie (1828 —).
10. Monatshefte für Chemie (1880 —).
11. Annales de chemie et de physique (1792 —).

Those listed under (*g*) are particularly valuable as reference works to the older literature, especially in patent cases and chemical litigation, while those given under (*h*) contain a fuller account of recent investigations. Advantage should always be taken of the fact that in many cases the decennial indexes may be consulted, thus saving considerable time. Furthermore, information is often obtained in a somewhat roundabout fashion, as for instance with regard to certain acetyl derivatives, by reviewing the properties of acetyl chloride or acetic anhydride on the one hand, and those of the amino or hydroxy derivative on the other.

The chemist will naturally be guided by such questions as the nationality and location of the men who have worked in this particular field as to the probable source of references covering the particular subject, so that very frequently much time may be saved by consulting such journals immediately without going through the whole of those specified above.

If the subject relates to dyestuffs or their intermediates, search should be made through the following journals and text-books:

(*j*) 1. Friedländer—Fortschritte der Theerfarbenfabrikation (1877 —).
2. Zeitschrift für Farben- und Textil-Chemie (1902 —).
3. Bulletin de la Société industrielle de Mulhouse (1831 —).
4. Bulletin de la Société d'encouragement pour l'industrie nationale.
5. Knecht, Rawson and Lowenthal—Manual of Dyeing.
6. Bucherer—Lehrbuch der Farbenchemie (1914).

If the search relates to a patented process, then a review should be carried out of

7. Winther—Patente.
8. Friedländer—Fortschritte der Theerfarbenfabrikation (1877 —).

In general, it may be said that when it is necessary to make a thorough investigation of the patent literature, it is, as a rule, advisable to confide this to some well known patent attorney, not only versed in patent law, but also possessing more than a passing acquaintance with chemistry, since the methods employed for locating foreign and other patent references call for specialized training.

The classified compendia issued by the British Patent Office will be found very useful in connection with research and especially patent investigations. As the British office data are classified according to subject they provide a valuable aid in reviewing the patent situation relating to any specific product.

It frequently happens that the chemist is called upon to ascertain whether some process has been tried out

previously on a technical, as distinct from a scientific scale, and in this case he should consult special monographs, and text-books on the subject, extending the search to all monographs, university theses, government and other special treatises dealing with the subject.

Certain technical journals dealing especially with applied chemistry should also be reviewed, for example:

(k) 1. Journal of Industrial and Engineering Chemistry (1909 —).
2. Chemical and Metallurgical Engineering (1902 —).
[Electrochemical Industry, I-II, 1902-1904; Electrochemical & Metallurgical Industry, III-VII, 1905-1909; Iron & Steel Mag. combined with last named, IV, 1906; Metallurgical & Chemical Engineering, VIII-XVIII, 1910-1918[1]; Chemical & Metallurgical Engineering, XIX- —, 1918[2]- —.]
3. Journal of the Society of Chemical Industry 1882 —).
4. Zeitschrift für angewandte Chemie (1887 —).
5. Revue générale de Chemie pure et appliquée (1899 —).
6. Chemiker Zeitung (1877 —).
7. Die Chemische Industrie (1878 —).
8. Revue de chimie industrielle (1890 —).

When the search relates to a specific subject such as explosives, rubber, pharmacology, gas, water, hygiene, etc., the special journals and text-books relating to them should be reviewed.

Search of Literature on Biochemistry

In view of the marked developments in the domain of biochemistry, it becomes of increasing importance for the organic chemist to keep in touch with this work. One of the best text-books on the relation between physiological action and constitution is Fränkel's Die Arzneimittel-Synthese.

For special methods reference should be made to:

Oppenheimer—Die Fermente und ihre Wirkungen (4th Ed., 2 vols., 1913).
Oppenheimer—Handbuch der Biochemie (4 vols. and supplt., 1908-1913).
Abderhalden—Handbuch der biochemischen Arbeitsmethoden (8 vols., 1910-1915).
Abderhalden—Lehrbuch der physiologischen Chemie (2 vols., 1914-1915).
Abderhalden—Physiologisches Praktikum (1912).
Hoppe-Seyler—Handbuch der physiologisch-und-pathologisch-chemischen Analyse (5th Ed., 1883).

For detailed information Abderhalden's Biochemisches Handlexikon (1911-1915) should be consulted.

In addition to these there is an excellent series of English monographs on biochemistry published by Longmans, Green & Co., and embracing fats, enzymes, proteins, etc.

List for a More Complete Search

If it is desired to make a more complete search of the literature, the following journals should be consulted:

1. Chemical Abstracts (1907 —).
2. Chemisches Centralblatt (1830 —).
3. Hoppe-Seyler—Zeitschrift für physiologische Chemie (1877 —).
4. Maly—Jahresbericht über die Fortschritte der Tierchemie (1871 —).
5. Centralblatt für Biochemie.
6. Centralblatt der exp. Medizin.
7. Koch — Jahresbericht über Gährungs-Organismen (1890 —).
8. Hofmeister—Beiträge über chemische Physiologie und Pathologie.
9. Biochemische Zeitschrift (1906 —).

Chemical Abstracts now makes a very complete review of work in this field. The earlier work is to be found by consulting the volumes indicated under lists *(g)* and *(h)*.

Inorganic and Mineral Chemistry

Unlike the literature of organic chemistry, where we have in Beilstein a "first aid" for the majority of inquiries, that of inorganic and mineral chemistry is scattered throughout the journals, books, monographs, etc.

In the first place, for reference to the general literature, the chemist should consult in the order named:

(p) 1. Gmelin-Kraut — Handbuch der anorganischen Chemie (5 vols., 1907-1914).
2. Hofman — Dictionary of the Inorganic Compounds (16 vols., 1910-1915).
3. Abegg — Handbuch der anorganischen Chemie (4 vols., 1905-1913).
4. Moissan—Traite de Chimie Minerale (5 vols., 1904-1906).
5. Dammer—Handbuch der anorganischen Chemie (5 vols., 1898).
6. Roscoe and Schorlemmer—Treatise on Chemistry (2 vols., 1911-1913).
7. Remsen—Inorganic Chemistry (5th Ed., 1907).
8. Molinari—General Industrial Chemistry (trans. Pope, 2 vols., 1912-1913).
9. Mellor—Modern Inorganic Chemistry (1912).

while other volumes of interest are:

10. Thorpe—Dictionary of Chemistry (5 vols., 1912-1913).
11. Watts—Dictionary of Chemistry (4 vols., 1911-1914).
12. Wurtz—Dictionaire de Chimie pure et appliquée (7 vols., 1892-1908).
13. Stähler—Handbuch der Arbeitsmethoden in der anorganischen Chemie (1913).

In addition the following journals should be reviewed:

(q) 1. Chemical Abstracts (1907 —).
2. Journal Chemical Society, Transactions and Abtracts (1849 —).
3. Chemisches Centralblatt (1830 —).

In general a good plan to follow is first of all to review thoroughly these three journals, list *(q)*, and then to proceed, according to the nature of the subject under review, to those journals which specialize in this field.

Mining and Metallurgical Chemistry

The chemist looking for specialized information will have to seek the same in a variety of text-books and publications, for example:

(a) Production of Metals.
(r) 1. Hofman—General Metallurgy (1913).
2. Roberts-Austen—An Introduction to the Study of Metallurgy (6th Ed., 1910).
3. Roberts-Austen—Metallurgy of the Common Metals.
4. Fulton—Principles of Metallurgy (1910).
5. Schnabel—Handbook of Metallurgy, Trans. H. Louis, 2 vols. (1905-1907).
6. Schnabel—Lehrbuch der allgemeinen Hüttenkunde, 2nd Ed., (1903).
7. Mineral Industry (1892 —).

and a variety of special treatises on individual metals such as

Peters—Copper Smelting.
Hofman—Metallurgy of Copper.
Clennell—The Cyanide Handbook.
Hofman—Metallurgy of Lead.
Ingalls—Metallurgy of Zinc and Cadmium.
Stoughton—Metallurgy of Iron and Steel.
Rose—Gold.

(b) Properties of Metals and Alloys.
(s) 1. Guertler—Metallographie (1912-1913).
2. Giua—Chemical Combination Among Metals (1918).
3. Howe—Metallurgy of Steel.

4. Howe—The Metallography of Steel and Cast Iron (1916).
5. Howe—Iron, Steel and Other Alloys (1906).
6. Law—Alloys and Their Industrial Application (1909).
7. Thurston—Treatise on Brasses, Bronzes, and Other Alloys and Their Constituent Metals.
8. Desch—Metallography (2nd Ed., 1913).
9. Ruer-Matthewson—The Elements of Metallography.
10. Sauveur—Metallography of Iron and Steel.

The following journals are devoted essentially to the subjects of mining and metallurgical chemistry:

(c) Mining Chemistry.
(t) 1. Engineering and Mining Journal (1869 —).
2. American Institute of Mining and Metallurgical Engineers—Bulletin and Transactions (1871 —).
3. Mining and Scientific Press (1848 —).

(d) Metallurgical Chemistry.
(u) 4. Chemical and Metallurgical Engineering (1902 —).
5. Journal of Institute of Metals (1909 —).
6. Internationale Zeitschrift für Metallographie (1911 —).
7. Iron Age (1834 —).
8. Journal Iron and Steel Institute (1869 —).
9. Brass World and Platers' Guide (1905 —).
10. La Metallurgie (1868 —).
11. Stahl und Eisen (1881 —).
12. Berg- und Hüttenmännische Zeitschrift — formerly Glückauf (1865 —).

(e) Applied Electrochemistry.
(v) 1. Transactions of American Electrochemical Society (1902 —).
2. Transactions of the Faraday Society (1905 —).
3. Electrical World (1883 —).
4. Zeitschrift für Electrochemie (1894 —).
5. Chemical & Metallurgical Engineering (1902 —).

The one journal devoted essentially to inorganic chemistry is Zeitschrift für anorganische Chemie (1892 —), while information of value is often to be found in Zeitschrift für angewandte Chemie (1887 —).

This is not intended to serve in any sense as a complete guide to the subject, but only as a general outline which will, it is believed, serve as a useful help and general guide. The ability to search the literature rapidly and efficiently is in part a question of experience especially as regards the various "short cuts" which can only be effected as a wider grasp of the field is acquired.

Special Literature for Specific Information

There is, in connection with each particular group, a certain definite territory consisting of special monographs, dissertations, journals, encyclopedias, etc., and the chemist will naturally direct his attention to them for specific information.

The abstract journal of the American Chemical Society is now covering the entire field in very complete fashion.

Certain of the journals have changed their names at various times—a fact to be borne in mind in reviewing the earlier literature. Furthermore the periodical indexes vary considerably as to the periods abstracted, and with regard to this point the chemist should consult the Catalogue of Scientific and Technical Periodicals (1665-1895), 2nd Ed. (1897), by Bolton, published by the Smithsonian Institution.

General Indexes

For information regarding titles and dates of publication of books, monographs, etc., on chemistry and allied subjects the following general indexes should be consulted:

1. Roorbach, O. R.—Bibliotheca Americana (1820-1861).
2. Kelly, J.—American Catalog of Books published in U. S. from Jan., 1861, to Jan., 1871.
3. Publishers Weekly — American Catalog of Books (1876-1910).
4. United States Catalog—Wilson & Co. (1900 —).

The last named is a five-yearly compilation of the "Cumulative Book Index"—Annual Catalog published by Wilson & Co.

In order that a technical chemist may keep up to date it is advisable that he should read regularly at least four or five journals, for example:

1. Journal of the American Chemical Society.
2. Chemical Abstracts.
3. Journal of Industrial and Engineering Chemistry.
4. Chemical and Metallurgical Engineering.
5. Journal of the Society of Chemical Industry.

The first two will give the chemist a fairly complete knowledge of the scientific chemical work being carried out in this and other countries, while the third and fourth will provide him with information on recent work and developments being carried out along technical lines. The fifth is valuable as a reference journal for information relating to patented processes, both here and abroad, and which are reviewed at greater length than in *Chemical Abstracts*.

The author wishes to acknowledge his appreciation of the kindness of the following gentlemen in favoring him with their criticism, suggestions and advice:

Dr. Colin Fink, Director Research Laboratories, Chile Exploration Copper Company, New York City; Dr. Roger Brunel, Professor of Chemistry, Bryn Mawr College, Bryn Mawr, Pa.; Mr. W. A. Hamor, Assistant Director Mellon Institute of Industrial Research, Pittsburgh, Pa.

360 Garden Ave.,
Mount Vernon, N. Y.

Manganese Ore

The United States Tariff Commission has recently completed the assembling of information on the manganese ore mining industry and has prepared an analysis of the competitive position of the United States in the manganese industry of the world. Among interesting facts recorded are the following:

Domestic production of high-grade (i.e., 35 per cent or more manganese) ore used largely for making ferromanganese increased from 4,063 tons in 1913 to about 294,000 tons in 1918. Production of low-grade (less than 35 per cent manganese) ore, used partly for making spiegel and partly smelted direct in iron furnaces, increased from 85,588 tons in 1913 to over 1,079,000 tons in 1918. The number of shippers of high-grade ore in 1918 had increased from 75 in 1917 to about 210.

Manganese mining on a large scale in the United States, however, is an artificial industry. The domestic ore is low grade, obtainable in small lots only, and variable in character. Aside from the higher cost of domestic ore as compared with the foreign product, any large dependence on domestic supplies involves the rapid depletion of our limited reserves.

The foreign resources are in some instances practically inexhaustible, are high grade and are more easily mined than the domestic deposits. The average grade of imported ore is 45 to 55 per cent manganese, compared with domestic "high grade" running 35 to 45 per cent.

Use of Army Gas Masks in Atmospheres Containing Sulphur Dioxide*

Adequate Protection Obtained From Army Gas Masks in the SO_2 Industries — Physiological Effect of Sulphur Dioxide — Canisters: Duration, Special Fillings and Sizes — Limitation of Gas Masks

By A. C. FIELDNER and S. H. KATZ

THE use of toxic gases in warfare has led to the development of an entirely new type of respiratory appliance, namely, the gas mask, which promises to fill a long-felt want in the chemical and metallurgical industries. Heretofore, workmen around plants using processes in which acid fumes are given off made shift to protect themselves, in more or less inadequate manner, by wearing moistened handkerchiefs, or respirators containing wet sponges, over the mouth and nose. The close of the war now makes available the army type gas mask, which is admirably adapted to filtering out many chemical fumes and acid vapors from inspired air, provided the concentration of gas is low (less than 1 or 2 per cent).

The possibility of using army masks around smelters and sulphide roasters for protecting the workmen from sulphur dioxide fumes was suggested, almost a year ago, by Mr. George S. Rice, chief mining engineer of the Bureau of Mines, and at his request several patterns of army masks were tested in various concentrations of sulphur dioxide to determine the degree of protection afforded. Owing to the pressure of military work and the inability of obtaining masks for industrial use, this investigation was not completed until after the signing of the armistice. The work is now completed, and the results are given in this publication.

Physiological Effect of Sulphur Dioxide

Sulphur dioxide is an irritating, irrespirable gas, relatively non-toxic as compared to carbon monoxide or oxides of nitrogen. There is very little danger from sulphur dioxide poisoning, as the fumes are so irritating that the victim is compelled to seek air at once. In extreme cases[1] of very high concentrations, when the victim cannot retire from the fumes, death may result from respiratory spasms and asphyxia. Ordinarily, however, workmen exposed for some time to a mild degree of sulphur dioxide poisoning complain of headache, anorexia, spasmodic cough, sneezing, hernoptysis, bronchitis, constriction of chest, gastro-intestinal disorders, conjunctivitis, smarting of eyes, lachrymation and anemia. For these symptoms workmen soon acquire toleration. The inhalation of large quantities of sulphur dioxide produces ulceration of the mucous membrane.

The Selby Smelter Commission[2] made a thorough investigation of the effect of various concentrations of sulphur dioxide on the senses of a number of persons. The average results of these tests are tabulated below:

Three to 5 parts per million (by vol.)—Plainly or faintly detectable by smell or taste.

Eight to 12 parts per million (by vol.)—Slight throat irritation and tendency to cough.

Twenty parts per million—Very distinct throat irritation, coughing, constriction of chest, lachrymation and smarting of eyes.

Fifty parts per million—More pronounced irritation of eyes, throat and chest, but possible to breathe several minutes.

One hundred and fifty parts per million (by vol.)—Extremely disagreeable but could be endured for several minutes.

Five hundred parts per million—So acutely pungent as to cause a sensation of suffocation, even with the first breath.

With no concentrations of less than 50 parts per million was there produced any feeling of nausea, and the tendency to nausea with the highest concentrations was only slight.

The authors repeated some of these experiments with substantially the same results; 370 parts per million (0.037 per cent) could be endured for only one-half minute.

Tests of Army Gas Masks

Early French Type:—The early French type of mask, shown in Fig. 2, consists of 40 thicknesses of cheesecloth, fashioned to fit over the entire face, from neck over chin to the hair above the eyes from ear to ear. Suitable rubber web bands held the mask closely to the face. Cellophane eyepieces were built into the mask at the eyes. The 10 outside layers of cheesecloth were impregnated with an unsaturated oil; the next 10 layers held an alkaline material; the next 10, hexamethylene tetramine; and the 10 next the face, nickel sulphate. The tests were made in a large airtight gas chamber, in which the sulphur dioxide atmosphere was produced by burning sulphur. The air was well stirred by two electric fans, running continuously throughout the tests. The concentration of sulphur was determined by titration with iodine. After the required concentration was reached, two observers, wearing carefully adjusted masks, entered the room. The results are given in Table I.

From the experiments in Table I it may be concluded that an atmosphere containing 0.16 per cent of sulphur dioxide may be safely entered and work performed by a person wearing a mask such as used in the experiments. Even though a mask were worn, it would be dangerous to attempt work in an atmosphere containing 0.20 per cent of sulphur dioxide, unless means of immediate exit were at hand and an observer watching from a place of safety to effect a rescue in case of necessity.

Prolonged exposure to sulphur dioxide, even in moderate concentrations, is undoubtedly injurious. Five

hours after the close of the above experiments, the observer who had been most exposed felt a soreness through the lungs and throat and the voice was slightly husky. The discharge from the nose was increased, and was slightly pink from blood. The next day he felt normal.

TABLE I—EFFECTS PRODUCED BY ATMOSPHERES CONTAINING VARIOUS PROPORTIONS OF SULPHUR DIOXIDE ON PERSONS WEARING FRENCH PATTERNED MASKS, FIG 2.

Test No.	Time	SO_2 by Iodine Per Cent	Effect on Wearer of Apparatus in Atmosphere
..	2:15	0.57	
1	2:31:00 to 2:31:45	....	Sulphur dioxide penetrated masks. The eyes could feel it, but were not disturbed much. The biting was severe in the air passages of the nose and throat. It could also be felt in the bronchial tubes and lungs. Observers could remain in this atmosphere only 45 seconds.
..	2:46	0.43	
2	2:58:00 to 3:03:00	....	The observers could just bear the sulphur dioxide that came through the masks. The biting in the air passages extended all the way to the lungs. Coughing was caused. The eyes were not bothered. The breathing was deep and difficult. In case of necessity, one could probably travel ½ mile in this condition. It was thought best not to remain in this atmosphere longer than 5 minutes. After coming into the fresh air, all the sulphur dioxide disappeared from the mask after three inhalations.
3	3:24:00 to 3:27:00	0.24	At first, one of the masks leaked at the sides, so that the eyes were bothered. After fixing this, the atmosphere was much better. The biting in the air passages was not so severe, but coughing was caused. It is probable that one could stand this atmosphere one hour, in case of necessity.
4	4:00	0.16	No difficulty was experienced in this atmosphere. The sulphur dioxide was noticeable and the throat was slightly irritated, but work could be done with hardly more trouble than that due to the mask itself.

Discomfort Caused by the Mask

The French type mask is an unpleasant apparatus to wear at best, although it imposes no marked hardship on the wearer. The face is heated, and the atmosphere breathed necessarily contains much exhaled air, and is hot and close. To determine the composition of the atmosphere within a mask while worn by a person at rest, two samples of gas were taken from a point ½ in. above the nostrils, the first, during periods of exhalation, the second, during periods of inhalation. The results are given in Table II.

TABLE II. COMPOSITION OF ATMOSPHERE WITHIN MASK WHILE WORN IN PURE AIR

No.	CO_2	O_2	N_2	
1	2.90	17.41	79.69	Sample taken during exhalation.
2	1.37	19.15	79.48	Sample taken during inhalation.

These tests show the bad effect of the large "dead space" in this type of mask. Even while at rest the wearer has to inhale 1.37 per cent of carbon dioxide, which contributes to the oppressive feeling produced by this mask. Aside from the question of rebreathing a certain proportion of exhaled air, this type of mask furnished so little protection against sulphur dioxide that it is of no practical value for use in the industries.

Mouthpiece Type U. S. Army Mask

The standard U. S. Army gas mask of the mouthpiece type is shown in Figs. 4, 7, 8 and 9. It consists essentially of a facepiece of rubberized fabric, impermeable to gas, connected to a canister containing the absorbents by a short length of flexible rubberized tubing. The wearer breathes through a rubber mouthpiece, the nose being closed by a spring clip, mounted on the inside of the mask. Leakage through the facepiece will only affect the eyes of the wearer, as the gas cannot enter the lungs. The inhaled air enters the bottom of the canister through a disk valve that closes on exhalation, the expired air passes out through a rubber flutter valve, projecting downward from the metal elbow tube just outside the facepiece.

The Type "F" standard army canister shown in section in Fig. 8 is 5½ in. high and contains 42 cu. in. of a mixture of cocoanut charcoal and "purple" soda lime and two cotton wadding filter pads, placed at one-third and two-thirds distance from the bottom, respectively. One of the authors, wearing this outfit, entered the gas chamber containing a concentration of 0.46 per cent sulphur and remained one hour, without detecting any gas whatever, except on one occasion, when the mask was disarranged, and then sulphur dioxide penetrated to and irritated the eyes. On adjusting the mask and clearing the facepiece, the gas disappeared, and no discomfort whatever was experienced thereafter from that source. During a part of the time, work was done on a bicycle dynamotor.

More sulphur was then burned, until a fog was produced in which objects could not be distinguished at distances beyond 4 ft. Analyses showed that the concentration was 1.17 per cent sulphur dioxide. No discomfort of any kind could be felt by the wearer, other than that due to the mask itself.

Life of Canisters in High Concentrations

Tests were made to determine the life of the standard Type "F" army canister in an atmosphere containing 5 per cent sulphur dioxide. The gas was put up in the chamber from a cylinder of liquid sulphur dioxide, attached to the chamber. Analyses of the chamber gas were made by drawing two liters of gas through a standard iodine solution and titrating back with standard sodium thiosulphate solution. Twenty canisters were tested, in lots of 10 each. The men did not enter the chamber, but were seated on the outside, wearing the facepieces, which were connected to iron pipes that passed through the walls of the chamber. The canisters were attached to the other end of these pipes on the inside of the chamber. As soon as a man detected gas coming through his canister, as shown by throat irritation, the time was taken, and the canister was considered exhausted.

Tested under these conditions, the 20 canisters served to remove all sulphur dioxide for periods of time varying from 18 to 41 min. The average service time was 29 min. The large variation in service time for the individual canisters was due, in part, to differences in the canister fillings, but mostly to differences in the breathing rates of the men. Individuals breathe different amounts of air. A small man may breathe only 5 liters per minute when at rest, while a large individual may require 10 or 12 liters. The average rate of a number of men, when at rest, is in the neighborhood of 8 liters per minute. Moderate exercise increases the rate to approximately 30 liters, and vigorous exercise causes a breathing rate of 60 to 70 liters. Hence, the efficient life of a gas mask canister is proportionately less when the wearer is engaged on continuous work.

In making these tests with high percentages (5.07 per cent) of sulphur dioxide, the canisters became quite warm after 15 min. use. A temperature of 80 deg. C.

was noted in some of the canisters. This elevated temperature made breathing rather uncomfortable toward the end of the test; however, all the men were able to continue breathing through the canisters until the gas finally penetrated the absorbent.

Practical Tests by Anaconda Copper Mining Co.

Several army masks of the mouthpiece type, Figs. 4, 7, 8 and 9 fitted with standard Type "F" canisters, containing soda lime and charcoal mixture with two cotton wadding filter pads, were tested under practical conditions by Mr. James Kane Murphy, assistant superintendent of the Washoe Reduction Works of the Anaconda Copper Mining Co., at Anaconda, Mont. The following paragraphs are quoted from his report:

"On Oct. 23, 24 and 25, we had considerable repair work to do on one of our Cottrell treaters; this treater takes one-quarter of the gas from roaster No. 2. During the repair work on this treater, it was shut off as tight as possible, but there was such a leakage of SO_2 gas that it was impossible for a man to enter the treater to do any work. The iron workers repairing this treater were able, two at a time, to put on these masks, and do their repair work in the treater. The men stayed in about 20 min. at one time; by that time, the heat and dust caused them to come out, but the masks were very satisfactory and work could be done with them by proceeding slowly.

"One test on these masks was performed in the No. 2 roaster ventilating tunnels when flotation calcine was drawn into cars ahead of the man with the gas mask on. It is absolutely impossible for a man without a mask even to attempt to stay in this place. Most of the dust coming from the cars, which were being loaded ahead of the man with the gas mask, will pass through 200 mesh, but none of the men wearing a mask in this place had any trouble with dust.

"A third mask was tested in a very high concentration of gas. The mask was carefully adjusted about the face and the person making the test was in an atmosphere containing about 5 per cent SO_2. Mr. E. A. Bernard, superintendent of calcining, personally put the mask on in this atmosphere, besides two other men. All decided that the gas came through the canister. This test was made on gas from the top hearth of an Anaconda type roaster furnace. The hearths on this furnace are similar to a Wedge roasting furnace. A steady wind was blowing against the east side of the furnace, so all doors on the top floor were opened, thus forcing a good part of the furnace gases out of the west doors. The testers stood as close as possible to the doors through which the gas came. This gas contains some SO_3, considerable moisture, dust, and some As_2O_3, besides the SO_2.

"If possible, we would like to have two more canisters for further testing of these masks, as they have proved to be very valuable in certain places, from the industrial point of view."

This reports that the simple army gas mask is exceedingly valuable around sulphide roasters and in fact any industry in which sulphur dioxide is given off. The third test, in which gas penetrated the canister, illustrates the limitation of this type of protective appliance. It must not be used in too high a concentration of gas. In this case, the percentage of SO_2 was probably higher than 5 per cent, as tests at the American University Experiment Station of the Chemical Warfare Service have shown that the standard army canister will remove 5 per cent of sulphur dioxide for at least 15 minutes.

Special Canister Filling for Sulphur Dioxide

The standard army canister contains 40 per cent soda lime and 60 per cent charcoal. The charcoal is of less value in absorbing sulphur dioxide than soda lime. Hence, for use in sulphur dioxide and dust an all soda-lime canister with cotton wadding filter pads will last from 50 to 100 per cent longer than the standard canisters used in the Anaconda tests. This is shown in the comparative canister tests with different fillings against ½ per cent SO_2.

TABLE III—SERVICE TIMES OF CANISTERS WITH STANDARD AND SPECIAL FILLINGS

SO_2 Concentration, 0.5% or 13.0 Mg per Liter; Relative Humidity, 50%; Average Temperature, 26° C.

Canister Filling	Service Time in Minutes	
	First Trace of Penetration	0.005 Per Cent SO_2 in Effluent
*Standard, 50 per cent charcoal, 40 per cent soda lime	32	36
Special, 100 per cent charcoal	7	57
Special, 100 per cent soda lime	54	..

* Average of five canisters tested.

The life or service time of the canister is the time in minutes during which all traces of SO_2 are absorbed by the canister. The breakdown of the canister is shown by the change in color of a sensitive potassium iodide-starch solution through which the effluent air from the canister is bubbling during the test.

Advantages of Larger Canister for Industrial Use

The standard army canister described in the foregoing tests contains 42 cu.in. of absorbent, weighs 1⅜ lb. and has a resistance to flow of 3½ to 4 in. water column at 85 liters per minute flow. This high resistance obliges men to work rather slowly while wearing the mask. A second disadvantage to which Mr. Murphy has called special attention is the short service time of the absorbent.

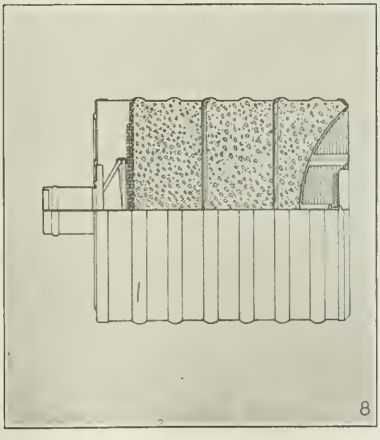
Both of these defects can easily be remedied by increasing the cross-sectional area of the canister without increasing the height in proportion.

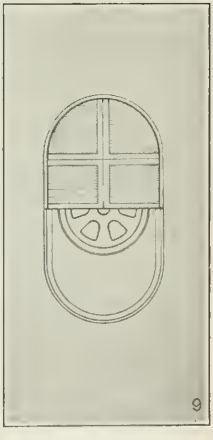
Recommended Type of Gas Mask

Although the mouthpiece type of mask was found fairly satisfactory in practical use, it is believed that the later type of Tissot mask, Figs. 5 and 6, in combination with a 100 cu.in. soda-lime canister will prove the best outfit for exclusive use in sulphur dioxide and acid gases. The elimination of mouthpiece and noseclip increases very materially the comfort, and enables the wearer to keep it on for hours at a time. The large eyepieces, held rigidly in proper position by the well-fitting substantial facepiece, afford a large angle of vision, thereby greatly increasing the efficiency of the workman wearing the mask. He should be able to do substantially the same amount of work as without the mask in a normal atmosphere.

Other Industrial Uses of Sulphur-Dioxide Respirators

Aside from the many metallurgical operations in which sulphur dioxide is given off, a respirator or gas mask designed for this purpose should be useful in sulphite pulp and paper mills; in sulphuric acid plants and





TYPES OF GAS MASKS USED IN WAR

1, Black veil with absorbent cotton saturated with sodium thiosulphate, carbonate and glycerine, effective against active gases such as chlorine. 2. Early French mask. 3. P. helmet saturated with $NaOC_6H_5$—effective against phosgene. 4. British type mask, mouthpiece and wiping fold. 5 and 6. Tissot masks, air inlet at eye, no noseclip or mouthpiece. 7, 8 and 9. Sectional drawings of British type U. S. A. mask.

in fact for protection against any acid gas such as chlorine, phosgene, carbon dioxide, hydrocyanic acid, oxides of nitrogen and hydrochloric acid.

Limitations of Gas Masks

In closing this paper, the authors feel it necessary to issue a most emphatic warning against the indiscriminate use of gas masks for any and all purposes. The soldiers in the army have been taught that their gas mask will protect them absolutely against any gas the enemy may put up. These men, on returning to civil pursuits, carry this idea with them. They will not realize that the extremely poisonous gases used in warfare are chemically active, and, therefore, combine readily with the absorbents of the gas mask. Furthermore, outdoor gas concentrations seldom exceed a few hundredths of 1 per cent. Some of the gases which are successfully absorbed by the mask at these battlefield concentrations will immediately penetrate it when present in quantities of 1 or 2 per cent. In fact, the army gas mask is useless against many of the most common industrial gases, as for example, carbon monoxide, ammonia, natural gas, producer and blast-furnace gas, mine gases, coal and water gas, and probably any gas when occurring in concentrations exceeding five per cent.

In such cases the self-contained oxygen breathing apparatus must be used, as the gas mask does not supply any oxygen whatever.

In view of these serious limitations, the gas mask should be used only with the advice of an expert who has a thorough understanding of the limitations of this apparatus.

Flotation Experiments on Hardwood Tar Oils

By L. F. Hawley[1] and O. C. Ralston[2]

THIS PAPER describes a continuation of the work started by Palmer, Allen and Ralston* on the testing of various flotation oils prepared from wood distillation products, especially the more neglected hardwood products. The tests reported in the first paper indicated the very desirable characteristics of various crude wood distillation products as flotation oil. In continuing the tests, the object sought was to determine, if possible, the relation between composition and flotation properties, or the constituent or constituents responsible for the good quality. Although neither of these points was satisfactorily settled, considerable information of interest was obtained.

Samples 106 to 109 were all from the same wood distillation plant, and except for 107 were taken from regular plant products without special preparation. As was explained in the previous publication, the crude settled tar is commonly distilled with steam for the recovery of the acetic acid and wood alcohol which it contains; this produces two oily products—the "wood oil" distillate, which was previously found to be a very good flotation oil, and the residual heavy tar, which had never been tested. Sample 106 is this heavy tar and 108 is the wood oil for comparison. Sample 107 is the heavy oil obtained by distilling a tar like 106 until a temperature of 265 deg. C. is reached. Sample 109 is a commercial sample of dissolved tar, the residue obtained after distilling the crude pyroligneous acid. Sample 110 is another heavy tar like 106, but obtained from a different commercial plant.

[1]Chemist, Forest Products Laboratory.
[2]Formerly Metallurgist, Bureau of Mines.
*Trans., Am. Inst. Min. Eng., 1916, p. 1387.

Results of Comparison

A comparison of this series shows that the three crude tar products produced in the regular course of operation of most hardwood distillation plants, viz., "wood oil," "heavy tar" and dissolved tar, are all better flotation oils that the distilled heavy oil which can be obtained by further distilling the "heavy tar." The regular crude tar-products are all very good and very much alike.

Samples 113 and 114 were from the same plant as 110. They represent the oils which settle out in the crude alcohol storage tank and in the alcohol refining still respectively. No. 113 was a heavy oil with gravity 1.021, and No. 114 a light oil with gravity 0.931. Neither of these oils was as good as the tars and wood oils, but they gave results much the same as the distilled oil No. 107, which they resemble somewhat in composition. Sample 115 was a dissolved tar similar to 109 except that it was made from resinous wood (southern yellow pine lightwood) instead of hardwood. It is seen to be slightly inferior to the hardwood dissolved tar. This material is not of much interest commercially, since only very small quantities are produced.

Tests Made on Pitch

As already stated, the tests on samples 106 to 109 showed that the oil distilled from heavy tar was inferior to the heavy tar itself. This suggested that the pitch which is the other constituent of the heavy tar (heavy tar = pitch + heavy oil) might be the constituent largely responsible for flotation properties. A series of tests was carried out with samples of pitch dissolved in low-boiling redistilled wood oil (No. 144), acetone (No. 150) and carbon tetrachloride (No. 151), together with samples of the pure solvents for comparison. All of these tests showed that pitch dissolved in solvents of low flotation value added considerably to the flotation value of the solvent, but in no case gave an oil comparable with the tar from which the pitch was prepared.

The natural combination of pitch and volatile oils found in hardwood tar is therefore a better flotation oil than the volatile oils alone, or than the pitch dissolved in other volatile oils of lower flotation value.

Tests to Determine How Much Pitch Is Necessary to Give Maximum Flotation Value to a Hardwood Tar

Another series of samples, Nos. 141-144, was prepared for the purpose of determining how much pitch was necessary to give the maximum flotation value to a hardwood tar. The series consisted of end members of straight settled tar (about 40 per cent pitch) and distilled oil (no pitch), and intermediate members of one part tar to one part distillate (about 20 per cent pitch) and one part tar to two parts distillate (about 13 per cent pitch).

It is difficult to explain these results on a basis of pitch content, since the samples with 40 per cent pitch and the 13 per cent pitch seem to be about the same, and both better than the 20 per cent and zero pitch sam-

ples. It is very apparent, however, that the crude settled tar without any distillation treatment is a much better flotation oil than the distillate obtained from it up to a temperature of 260 deg. C., and as good an oil as can be obtained by mixing the distilled oil with the original tar. This conclusion corresponds well with that in regard to the relation between the heavy tar (tar from which light oils had been removed) and the oil which can be obtained from it by distillation (heavy oils only).

Removal of Alkali-Soluble Material Seems to Improve Oil for Flotation Purposes

Samples Nos. 146 and 147 were prepared and tested to settle a question which arose in connection with the operation of a plant producing distilled tar oil for a flotation oil. It was desired to extract part of the alkali-soluble material from a part of the distilled oil for use in manufacture of medicinal beechwood creosote, but it was not known what the effect of such partial extraction might be on the value of the residual oil for flotation purposes. Sample 146 was a straight distilled oil with boiling points 180-260 deg. C., while No. 147 was the same except that 40 per cent of the alkali-soluble material of the fraction 180-260 had been removed. The removal of this alkali-soluble material seems to have improved the value of the oil for flotation purposes, and this result indicates that the raw material for medicinal creosote can be removed from hardwood tar flotation oil without diminishing the value of the latter.

Commercial Tests Made

In order that the laboratory tests might be further checked, two of the promising oils were obtained in larger quantity and large samples sent to a number of prominent metallurgists in charge of representative plants with the request that they give them commercial full-scale tests in their mills, or semi-commercial tests in single units. The Anaconda Copper Co. tested the oils for both their copper and their zinc ores. The Bunker Hill and Sullivan tested the oils for their silver-lead ore, and a number of other operators did likewise. The oils did not meet with universal success in the treatment of all ores, but were found to be very satisfactory for some of them, and in a number of cases seemingly the full equivalent of the more expensive pine oils. The two oils tested were the commercial (hard-) wood oil (similar to No. 108) and the crude settled tar (like No. 141), both of which are produced in nearly all ordinary wood distillation plants, and whose recovery does not involve much special machinery.

Reports on Commercial Plant Tests

The following extracts from three reports on commercial plant tests indicate the results obtained more specifically:

A. "I am enclosing a report . . . on experiments with Nos. 1 and 2 hardwood oils. . . . It would seem that they are as effective on our ores[3] as steam distilled pine oil."

No. 1 is the same as No. 141 in Table I. No. 2 is the same as No. 108 in Table I.

B. "Both oils acted much the same on copper ore, but in the case of tests on zinc ore the tar did not give as good results as the oil. . . . These oils are worthy of consideration for use as flotation reagents. They would not give good results if used alone, but fair results should be obtained when used in conjunction with kerosene acid sludge."

C. "We have tested the sample of hardwood oil[4] which you recently supplied with the following results:

Date	Hours Run	Assay Concentrate Pb	Assay Concentrate Ag	Assay Tailings Pb	Assay Tailings Ag	Extraction Pb	Extraction Ag
14	20	44.9	24.5	1.21	0.60	84.0	83.6
15	24	49.2	26.2	1.28	0.60	82.5	83.1
16	24	48.2	25.8	2.21	1.00	69.1	71.5
17	24	52.5	26.5	1.52	0.70	78.9	80.2
18	24	51.4	25.2	1.40	0.70	80.7	80.3
19	24	45.9	23.1	0.98	0.40	86.8	89.1
20	12	47.2	24.8	0.70	trace	90.2	94.5
Average.....		48.4	25.3	1.38	0.63	81.1	85.0

Treatment in Regular Mill Operation

"This was in regular mill operation and no effort was made to get especially good results. We had considerable trouble feeding the oil, as our feeding devices are all of the drip type. This, of course, would be easy to remedy if we used this type of oil. The oil consumed over the period averaged 0.2 lb. per dry ton of feed. The results compare very favorably with those obtained from the use of pine oil and creosote."

TABLE I—RESULTS OF FLOTATION TESTS *

Sample No.	Description of Oil Used	Pb Per Cent in Concentrate	Pb Per Cent Extraction	Zn Per Cent in Concentrate	Zn Per Cent Extraction
106	Heavy tar	21.6	88.1	24.7	88.4
107	Oil, from 106 up to 265 deg. C.	24.8	85.5	18.3	66.6
108	Commercial "wood oil"	25.6	84.1	22.8	89.3
109	Dissolved tar	26.6	85.5	22.8	89.1
110	Heavy tar	19.0	92.3	18.9	87.4
113	Light oil from alcohol still	22.6	85.0	22.6	63.7
114	Heavy oil from alcohol still	20.9	73.8	20.2	67.0
115	Dissolved tar from pine wood	16.9	81.0	19.4	90.2
141	Crude settled tar	21.9	75.4	32.8	75.3
142	1 part 141 and 2 parts 144	24.5	78.8	32.3	61.5
143	1 part 141 and 1 part 144	22.8	67.0	32.8	54.5
144	Distillate from 141	26.6	59.8	30.8	33.5
146	Distillate 180-260 deg. C.	22.1	69.5	23.1	57.0
147	146 partly extracted with alkali	17.0	75.0	20.7	74.5
149	Pitch disolved in redistilled low-boiling wood oil	22.5	33.8	29.8	28.0
149B	Redistilled wood oil	24.3	31.2	37.4	23.7
150	Pitch dissolved in acetone	29.1	28.7	31.0	17.8
150B	Acetone	29.5	12.8	13.5	15.3
151	Pitch dissolved in carbon tetrachloride	29.5	59.5	32.5	19.0
151B	Carbon tetrachloride	31.4	32.8	12.2	0.0

*All the figures given in this table were obtained by tests in alkaline circuit. All the samples were tested also in acid and neutral circuit, but in most cases the results obtained with alkali were very much better, and the above figures are considered to give the best comparison of the different oils. As mentioned in our first paper, the tests were performed in a laboratory Janney flotation testing machine on a mixed zinc-lead sulphide ore.

Conclusions

We have found that some of the crude hardwood distillation products, as now prepared in many plants, are adapted to satisfactory flotation of a number of ores. An attempt to determine which constituents of the oils were of most value in flotation gave negative results, and it seems that the crude products are as a rule better than any of the fractions or refined products made from them. In other words, a *mixture* of different oils is more likely to do good flotation work than any one product alone. In spite of the fact that there is considerable prejudice against all resinous wood distillates which contain pitch, the statement being made that they spoil the "selection" of the oil and produce dirty flotation concentrate, we have not found hardwood pitch undesirable in most of the mixtures tested.

[3]The ore is a galena carrying silver.

Determination of Uranium, Zirconium, Chromium, Vanadium and Aluminium in Steel—II

By Charles Morris Johnson

TO DETERMINE the amount of aluminium and zirconium in steel dissolve 4 g. of sample in 50 cc. of 1:3 H_2SO_4 diluted with 50 cc. of water. After action is over, filter off the insoluble residue, which is mainly carbides. Wash the carbides 25 times with dilute H_2SO_4 wash. Call this filtrate and washings *A*. The insoluble carbides will contain some Al and Zr. Ash the same in a platinum crucible at a low red heat. Cool; add 6 cc. HF plus 6 cc. of 1:3 H_2SO_4; evaporate to thick fumes; cool; add a little water, heat until all sulphates are in solution and add latter to *A*. Dilute *A* to about 250 cc. volume with water and add 1:1 ammonia with constant stirring until the first appearance of a black precipitate forms. Add a few drops in excess. At this stage all the zirconium and aluminium have been precipitated with a very small percentage of the iron. Filter off at once and redissolve precipitate in 50 cc. of hot 1:1 HCl. Wash the paper with dilute HCl wash till it looks perfectly white. Concentrate the filtrate and washings to about 50 cc. volume and peroxidize with sodium peroxide till the solution is alkaline. This peroxidization is carried out in the following manner: add from a small porcelain spoon about 1 g. at a time of Na_2O_2. Rinse off spoon into beaker with each addition of the peroxide and stir the solution each time, and so on until the solution is alkaline. By this process the volume reaches about 300 cc. by the time it is alkaline. Then add 5 g. of Na_2CO_3; bring it just to a boil and filter off the iron and zirconium. Wash precipitate with water about 25 times. The filtrate contains the aluminium. Redissolve the iron and zirconium in 50 cc. of hot 1:1 HCl and peroxidize again as before to remove the last traces of aluminium.

Add to the filtrate 1:1 HCl with constant stirring until turmeric paper does not change even to a faint brown when dipped in the solution, but red litmus paper gives an alkaline reaction. Keep cover on while adding the acid. Let aluminium settle for a few hours and after filtering it off, wash it about 40 times with ammonium nitrate wash. Redissolve the aluminium with hot 1:1 HCl, wash it with dilute HCl water. (Wash the papers also with water and burn off with the main precipitate, as some aluminium is liable to remain in the papers.)

To the filtrate and washings add 1:1 ammonia till slightly ammoniacal. Aluminium is precipitated. Now bring it to a boil, filter it off and wash it free of chloride. Burn it off in a weighed platinum crucible to a constant weight. Remove the silicon by evaporation with HF and a few drops of 1:3 H_2SO_4; again weigh as Al_2O_3. Multiply by 0.53033 to calculate to metallic aluminium.

Iron and Zirconium

The iron and zirconium on the filter are dissolved in 30 cc. of hot 1:3 H_2SO_4 diluted with 50 cc. of water. Wash the paper about 40 times with dilute sulphuric wash. Add to the filtrate 20 cc. of a saturated solution of Na_2HPO_4 (di-sodium phosphate); stir well. Add 1:1 ammonia slowly till a precipitate just starts to form. Zirconium phosphate comes down at this stage with very little iron, as the solution is still acid and most of the iron is in solution. The more zirconium with the sample the less ammonia it is necessary to add before a precipitate starts to form. After a few hours, preferably over night, filter off the zirconium phosphate plus some iron phosphate, plus some silicon. Wash the phosphate with water 40 times. Burn it off in a weighed platinum crucible. Add about 10 drops of conc. sulphuric acid and 10 cc. HF. Evaporate just to SO_3 fumes. Transfer the insoluble residue into a beaker. The iron phosphate will be in solution as iron sulphate, while the zirconium phosphate is insoluble. Warm the solution for a while to redissolve the iron sulphate that may be separated out. Filter off the insoluble residue, wash it about 50 times with water and burn it off in the same platinum crucible. (Some of the zirconium may stick to the crucible and cannot be transferred to the filter.) Burn it to a constant weight and weigh as zirconium phosphate, using the original weight of the crucible gotten just before the zirconium phosphate plus a little iron phosphate was burned in it. Multiply by 0.3838 to calculate to zirconium.

Standards were prepared by adding a known weight of metallic test aluminium and ZrO_2 (zirconium alba) to a plain steel: treated the same way as the samples. The recoveries are accurate. See table below.

TEST MIXTURES OF Fe, Al, and Zr

(1) Fuse ZrO_2 with potassium bisulphate, dissolve the melt in dilute sulphuric acid to get it in solution.
(2) Dissolve metallic aluminuim in 1:1 HCl; fume it with sulphuric acid. Dissolve in water to get it in solution.
(3) Pour (1) and (2) into the sulphuric acid solution of the drillings of the plain steel.

Recoveries	
Added	Found
0.015 g. aluminium	0.0164 g. aluminium
0.030 g. aluminium	0.0310 g. aluminium
0.050 g. aluminium	0.0495 g. aluminium
0.025 g. aluminium	0.0265 g. aluminium
0.0110 g. zirconium	0.0108 g. zirconium
0.0220 g. zirconium	0.0214 g. zirconium
0.0368 g. zirconium	0.0365 g. zirconium
0.0184 g. zirconium	0.0185 g. zirconium

Sample of so-called "zirconium steel" submitted to the author for analysis.
Sample A—Al, 0.41 per cent; Zr, 0.13 per cent; Si, 0.77 per cent.
Sample B—Al, 0.56 per cent; Zr, 0.17 per cent; Si, 0.75 per cent.

Aluminium in Plain Steel

Dissolve on a low flame 5 or 10 g. of steel in 50 cc. 1:3 H_2SO_4 diluted with 50 cc. of water. After action is over, filter off the insoluble residue, which is mainly carbon and carbides, wash it 25 times with dilute H_2SO_4 wash. Call this filtrate and washings *A*. The insoluble residue may contain Al, so it must be ashed in a platinum crucible at a low heat; cooled; 6 cc. of HF + 6 cc. of 1:3 sulphuric acid added; evaporated to thick fumes of SO_3; cooled; a little water added; heated to dissolve the sulphates, and the clear solution is added to *A*. Then dilute *A* to 250 cc. volume with water, and add slowly 1:1 ammonia with constant stirring, until the reddish precipitate changes to a blackish. All the aluminium is precipitated with but 3 or 4 per cent of the iron. Filter aluminium plus a little iron off at once; redissolve it in 50 cc. hot 1:1 HCl, pouring the acid back and forth until all the iron and aluminium is in solution. Wash the filter paper about 40 times with dilute HCl water. Peroxidize the filtrate with sodium peroxide until the solution changes red litmus paper to a blue. Add about 5 g. of sodium carbonate; bring it to a boil and filter off the iron. Wash the precipitate about 30 times with water.

If the pulp mixed with the precipitate is washed thoroughly no more aluminium will be left with the iron,

otherwise it is necessary to redissolve the iron in hot 1:1 HCl and make another peroxidation. To the filtrates add 1:1 HCl with constant stirring until turmeric paper does not change even to faintest brown when dipped into the solution, but red litmus paper turns slightly blue when dipped into it. Aluminium is precipitated at this stage. After a few hours, especially when aluminium per cent is low, filter off the precipitate and wash it about 40 times with ammonium nitrate, to remove the salts as far as possible. To free the aluminium from all sodium salts the aluminium is redissolved in 50 cc. hot 1:1 HCl. Wash filter 40 times with dilute HCl wash. (Wash the filter paper free of chloride with water and save it to burn with the main final precipitate, as aluminium is liable to remain in the filter.)

Precipitate the aluminium by adding 1:1 ammonia to the filtrate until faintly ammoniacal. Bring it to a boil and filter off the aluminium hydroxide. Wash it free of chloride with ammonium nitrate. Burn off in a weighed platinum crucible and blast it to a constant weight. Weigh it as Al_2O_3 plus SiO_2. Remove the silica by evaporation with a few drops of 1:3 H_2SO_4 and 10 cc. of HF. The remainder is Al_2O_3. Multiply by 0.53033 to calculate to aluminium.

ALUMINIUM RECOVERIES FROM STEEL

Weight of Steel Taken, G.	Aluminium Added, G.	Aluminium Found, G.
15	0.010	0.0102
10	0.020	0.0199
5	0.050	0.0508
5	0.030	0.0300
5	0.100	0.1005

Same weights of steel without any aluminium added were put through all of the foregoing operations and the blanks found were deducted from the above five samples.

Note: Dissolve the metallic aluminium in 1:1 HCl, fume it with 1:3 H_2SO_4; dissolve in water; add the aluminium sulphate solution to H_2SO_4 solution of the drillings, when making up standards, as metallic aluminium is only slightly soluble in 1:3 sulphuric acid,

Chromium and Vanadium

For determination of small amounts of chromium and vanadium, dissolve 5 to 10 g. of steel in 50 cc. 1:3 H_2SO_4, dilute with 50 cc. of water, using a 600 cc. beaker. After action is over, filter off the insoluble residue, wash it about 15 times with dilute sulphuric acid.

The insoluble residue is then washed off into the original beaker and held for further treatment to be described later. It will contain much or little of the Cr and V, depending on the total percentage of carbides present. The filter paper may still contain a little V and Cr in its pores. Ash it in a porcelain crucible; dissolve it in a few drops of conc. HCl with heat; fume with 5 cc. 1:1 H_2SO_4 to remove HCl. Add it to *A*.

Dilute the filtrate from the insoluble carbides at once to about 200 cc., and add 1:1 ammonia slowly with constant stirring till a black precipitate forms. At this stage, add drop by drop about 2 cc. of ammonia in excess to assure a complete precipitation of all the chromium and vanadium with very little iron.

Filter at once and redissolve in 50 cc. 1:3 H_2SO_4. Wash paper 25 times with dilute sulphuric acid wash. Pour filtrate and washings into the original beaker containing the insoluble residue (vol. at this point should not be more than 100 cc.). Heat beaker for a while and add 40 cc. of 1:20 HNO_3 to oxidize all carbides (*A*).

Continue to heat until any tungsten carbide present is yellow. By this time vanadium and chromium will be in solution, or if no tungsten is present, heat until all red fumes are gone and the residue is white and floating. Boil a few minutes and then add permanganate from a pipette a little at a time until a brown precipitate of manganese oxide forms that does not dissolve after 20 min. boiling. The boiling with permanganate brings the chromium and vanadium to their highest stage of oxidation.

Filter off the excess of manganese oxide together with some silicon and tungsten, if any is present. Use a heavy suction bottle and a porous crucible (zirconia crucible is preferred).

Wash the residue in the crucible about 15 times with water only. Transfer to clean beaker, volume about 300 cc. Finish as usual for chromium and vanadium with ferricyanide as an internal indicator. See the writer's method, "Rapid Methods for the Chemical Analysis of Special Steels, etc.," second edition, pages 7, 8, 9, 10, 11, 12 and 35-42.

The advantage of the method of course is to remove the bulk of iron, thus enabling the operator to take larger weights of sample. In this way a steel containing 0.01 to 0.02 per cent Cr or V, or both, can be analized with just as much accuracy as one containing 1 or 2 per cent Cr and 0.25 per cent V, or higher.

TABLE SHOWING RESULTS OBTAINED BY METHOD ON KNOWN STEELS

Steel Taken, Grams	Chromium Added, Per Cent	Results Found, Per Cent	Vanadium Added, Per Cent	Results Found, Per Cent	Blank, cc.
5	3.070	3.000	0.043	0.056	1.6
10	0.274	0.278	0.040	0.030	1.5
9	0.545	0.550	0.024	0.020	1.5
10	None	None	0.115	0.112	0.6
10	None	None	0.076	0.076	0.6
Cr-V-W steel 2 g	3.630	3.61	0.830	0.820	...
Cr-V steel 5 g	1.060	1.08	0.254	0.244	...

Steel 2 g	None	None	1.913	1.879	0.3
Cr-V-W steel 2 g	2.750	2.72	3.190	3.230	...

Much credit is due to Mr. Max Engleman for the painstaking way in which the analyses were carried through to get the analytical proof given in the foregoing tables of recoveries for uranium, zirconium, aluminium, chromium and vanadium.

Copper, Nickel, Titanium and Tantalum

In all probability, the same scheme of precipitating the element away from the bulk of the ferrous iron by ammonia will answer equally well for the determination of large and small percentages of titanium and tantalum. Perhaps also for small amounts of copper and nickel. The author will make this a subject for later publication.

Crucible Steel Co. of America,
Pittsburgh, Pa.

Civil Service Examination

Oil Chemist (Male).—Salary $1200 to $1400. Duties will include the physical and chemical examination of hydrocarbon oils, fatty oils, oil residues, distillates, partial oxidation products and gases. File applications before June 24.

Temperature Observations on Heating, Quenching and Drawing of a Large Steel Forging

Determination of the Rate of Heating and Cooling of Large Masses of Steel—Arrangement of Thermocouples—Furnace and Forging Temperature Curves—Inverse Rate and Temperature-Seconds Curves

By O. A. KNIGHT* and F. F. HANSEN†

THE following experiment was conducted by the authors at the heat-treating plant of the Watertown Arsenal. An experiment closely approximating this one was carried out in the summer and fall of 1914 at the plant of the Midvale Steel Co. and is given in a report by Mr. M. E. Leeds in the *Proceedings* of the American Society for Testing Materials, Vol. XV, Part II, 1915, page 5. The results recorded in the present paper are, however, not in agreement with those reported by Mr. Leeds as regards the relation of temperature of forging to temperature of furnace.

The object of this investigation was to obtain accurate data on the rate of heating and cooling of large masses of steel. In addition to this it was desired to determine the relation existing between the temperature of the furnace and the temperature of the mass of steel on heating to, and holding at, the maximum temperature employed. The rate of cooling when the forging was oil quenched was also determined and the inverse rate cooling curve plotted.

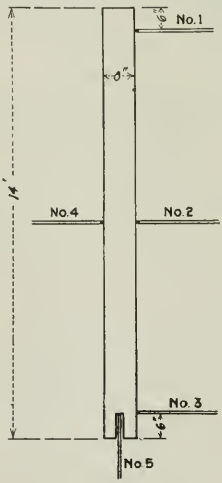
The inverse rate cooling curve, shown in this report, illustrates clearly that even with large masses of steel the critical transformation point is well defined. The heating curves show that the forging never attained the temperature of the furnace, but that on the contrary even though the temperature of the furnace was held constant for over an hour the temperature of the forging remained likewise constant, but was several degrees lower.

A study of the heating curves indicates that for any given temperature of furnace the maximum temperature to which the interior of the mass of steel will rise is soon established. The curves indicate that the higher the temperature the more nearly does the temperature of the steel coincide with that of the furnace. It is also shown that a large piece such as used in this experiment does not lose an appreciable amount of heat during a short interval of time in the air which must occur during the transfer of the piece from the furnace to the quenching bath.

The rate of cooling of a large piece when quenched in oil is far from being as rapid as is generally supposed. Thirteen minutes was required to cool the forging in question from 800 deg. to 300 deg. C. and 23 minutes to cool from 800 deg. to 200 deg. C.

The observations in this experiment were made on a forging 14 ft. in length by 8 in. in diameter. The forging was heated in a vertical oil-fired furnace, being handled and held in proper position by an overhead crane. Five base metal thermocouples were used in making the temperature measurements. All were carefully calibrated against a platinum standard before being used. One was placed near the top, two near the middle and one near the bottom of the forging with the hot junction of the couple in each case approximately 2 in. from the forging. These couples were protected by being properly insulated and enclosed in iron pipe. The fifth couple employed was inserted in the center of the lower end of the forging to a depth of 6 inches. The arrangement of the couples is shown in the accompanying sketch.

The long couple inserted in the lower end and used in determining the temperature of the forging was carefully insulated and after the hot junction was inserted to the proper depth it was carefully padded with asbestos felt and covered with sodium silicate (water glass) to exclude all furnace gases or oil which might otherwise influence the results. All of the couples were of the base metal type made from iron and constantin wire. The four used in determining the furnace temperature, i.e., placed near the surface of the forging, were connected to a Leeds & Northrup six-point recording potentiometer. The one inserted in the forging was connected to a portable potentiometer of the same make. With this arrangement for determining temperatures the data herein recorded may be taken to be accurate at least to a limit of 10 deg. C., since both the instruments and couples were carefully calibrated immediately before use.

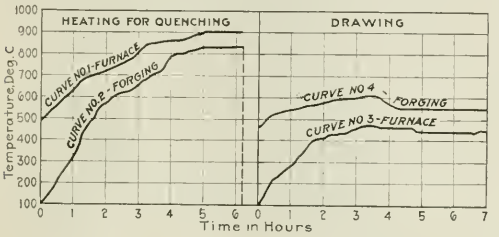


ARRANGEMENT OF COUPLES

The forging was gradually heated to 835 deg. C. and held approximately one hour at that temperature before quenching. The total time of heating was a little over six hours. After holding the forging at the temperature of 835 deg. C. for the desired time it was removed from the furnace and quenched in cottonseed oil. The total time expiring from the time the forging was withdrawn from the furnace to the time when it was quenched was 10 minutes. During this time in the air the piece cooled 8 deg. C. as measured by the couple inserted in the end.

*Asst. Metallurgist, Watertown Arsenal.
†Asst. Supt. Heat-treating Dept., Bethlehem Steel Co.

A study of the curves submitted with this report will bring out many points of interest. First, it will be noted at the beginning of operations, when the temperature of the furnace, as indicated by the average of the four couples near the surface of the forging, all of whose readings closely agreed, was 480 deg. C., that of the forging was only 100 deg. C. Curves No. 1 and No. 2 of the furnace and forging respectively are plotted

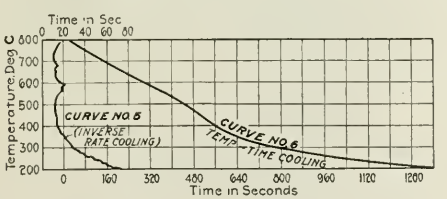


time as abscissa and temperature as ordinate. The temperature readings were taken every 10 minutes.

It will be noted that the temperature of the furnace was at no time attained by the forging, and the lower the temperature the greater the difference in temperature of furnace and forging. It will be further observed that holding the furnace temperature constant at 900 deg. C. for slightly over an hour imparted a uniform temperature of 835 deg. C. to the forging.

This is not at all in agreement with the data recorded by Mr. Leeds in his report previously referred to. The greatest difference he recorded between the temperature of the furnace and the center of the 12-in. specimen is shown in curve C, Fig. 5, of his report and is approximately 40 deg. F. at the end of a total heating of 7 hours.

Curves No. 3 and No. 4 show a similar relation between the temperature of the furnace and the temperature of the forging during the drawing operation. In the report by Mr. Leeds at the temperature of 1000 deg. F. (538 deg. C.) the temperature of forging



differs from that of the furnace by only a few degrees F. From curves No. 3 and No. 4 of the present report it is seen that while the temperature of the furnace is maintained constant at about 550 deg. C., the temperature of the forging is practically 100 deg. C. lower; thus a considerable difference exists in the two records taken. The curves submitted in the present report are plotted exactly from the data obtained without smoothing out any irregularities whatever.

Inverse rate and temperature-time curves plotted from the data obtained on cooling the forging in oil are also shown. It is to be noted that the rate of cooling is by no means as fast as commonly supposed to result from oil quenching. The transformation at the critical point on heating was so distinct that it could easily be detected while observing the electromotive force indicated by the couple. The temperature actually remained constant a short time at this point, which was 702 deg. C. The critical point on cooling is also quite plain in the inverse rate cooling curve. It occurred at 590 deg. C. as shown.

It is the hope of the authors of this brief paper to present at some future date more detailed data upon this subject, with the time of holding at the maximum temperature materially lengthened.

Metallic Coatings for Rust-Proofing Iron and Steel—III. Bibliography

By Henry S. Rawdon[1], M. A. Grossman[2] and A. N. Finn[3]

THE bibliography of the general subject of corrosion is extremely voluminous; probably more has been written on this subject than on any other phase of physical metallurgy. Many of the articles merely reiterate statements which have previously been published. Below is given a list of the most helpful contributions to the discussion of different phases of the subject as related to the rust-proofing of iron and steel by means of metallic coatings. The references to the literature throughout the text have been made by referring to the proper number in the first column:

Synopsis of Recent Chemical and Metallurgical Literature

Chemically Reactive Alloys.—E. A. ASHCROFT, in a paper recently read before the Faraday Society, described the properties of the binary system magnesium-lead. An alloy containing 15 per cent Mg when exposed to humid atmosphere will oxidize completely in a few hours to a jet-black powder, a mixture of hydrates and lead suboxide. This reaction can be used to remove the last traces of oxygen in a gas mixture or for the manufacture of small amounts of atmospheric nitrogen. Alloys with 35 per cent Mg rapidly decompose water at 150 deg. C. with the formation of metallic oxides and hydrogen, which reaction is very useful in aëronautics, requiring only a steam boiler and a readily transported alloy. The alloys are easily made by melting the primary metals under cover, or more preferably, by the electrolysis of fused anhydrous $MgCl_2$ over a cathode of molten lead.

Calcium-lead alloys act somewhat similarly, but not so rapidly. Zinc-magnesium in similar proportions, on the other hand, appears to be less readily oxidized than either component alone.

Corrosion of Condenser Tubes.—The fourth report of the Corrosion Committee of the Institute of Metals was presented in summary at the April, 1919, meeting, by G. D. BENGOUGH and O. F. HUDSON. Corrosion of zinc in distilled and sea water is regarded by the authors as being a process of chemical oxidation rather than electrochemical displacement, wherein H_2CO_3 locally dissolves the protective scale of oxide or basic carbonate existing on normal metal, baring a true metallic surface where a peculiar oxide—probably containing zinc peroxide—forms, which is slightly soluble, but is later precipitated as the ordinary hydroxide and carbonate, forming a protective coat.

Corrosion of pure copper is also chemical. A lower oxide (Cu_4O or Cu_2O) is formed on immersion which is protective but is slowly peroxidized into cupric hydroxide or basic carbonate. This in turn flakes off due to the formation of underlying bulky products: porous and amorphous oxides, slightly soluble. Pronounced local action does not occur.

When coupling electrodes of different metals the corrosion was often at variance to electrode potential lists, and the authors think that the effects of electrolytic corrosion have been over-emphasized, since sufficiently good contact is difficult to get. For instance, a metal may be oxidized and go into solution in spite of the fact that it is continuously cathodic.

Severe pitting of aluminium and some light alloys at the water line is shown to be due to the presence of strongly acid salt. Brass (70: 30) corrodes by solution of some zinc and a little copper in H_2CO_3, the remainder of both adhering as an oxide scale, becoming further oxidized locally and covered with thick porous deposits of the products of attack. Attack is accompanied by redeposition of copper, and is uniform in nature rather than a local dezincification. Pitting is due to accumulation of the products of corrosion, especially in sea-water.

A table (Table I) is presented of condenser tube troubles and remedies. In order that a tube may have a minimum life of 20 years, only clear water leaving no sediments should enter, this water to be neutral and free from gases in suspension or abnormal amounts in solution, not more than 35 deg. C. in temperature at the hottest region. Condenser water should travel about 5 or 6 ft. per second and the steam should be properly distributed. In practice quick failures are due to the fact that the normal slow roughening by chemical oxidation is locally accellerated by factors independent of the tube.

TABLE I—CAUSES OF CONDENSER TUBE AND FERRULE CORROSION. (WATER SIDE ONLY CONSIDERED)

Cause	How Produced	Nature of Action	How to Be Remedied
A. Foreign bodies carried in and accumulation of products.	A1. By ferric hydrate flakes from water ends. A2. By ashes, clinkers, etc. A3. By sludge of sorts in water supply.	Complete corrosion of the oxide disintegration type, causing local action.	A1. Paint the pipe line and water ends. Increase water speed. A1, A2, and A3. If worth while trap the water supply or pass it through a screen. In some cases increase water speed.
B. Acid or other bad or variable water supply.	B1. Some river supplies, *e.g.* Tyne. B2. Some canal supplies, *e.g.* ship canal. B3. Some well supplies. B4. Some estuarine supplies. B5. Some cooling tower arrangements.	Complete corrosion and rapid general thinning. Sometimes slight uniform dezincification.	Keep water supply slightly alkaline. Use special tubes adapted to the special conditions.
C. Temperature in condenser too high.	C1. Hot inlet water, *e.g.* tropical. C2. Slow water speed. C3. Partial blocking of tubes.	C1. Dezincification. C2. Dezincification. C3. See A3.	C1 and C2. Use special tubes. C2. Increase speed. C3. See A3.
D. Undue aëration.	D1. Errors in pump and pipe line arrangements. D2. Eddies near inlet causing water-line effect.	D1. Complete corrosion of oxide disintegration type. D2. Complete corrosion of pitted areas.	D1. Remedy air leaks, etc. D2. Special ferrules. Possibly increasing speed of water with modified design of water end.
E. Unsuitable composition of tube.	E1. Zinc or impurities in too great amount. E2. Surface of tube not sufficiently copper rich.	E1. Varies. E2. Dezincification.	E1. In manufacturing. E2. Probably by attention to details of annealing and pickling during manufacture.
F. Defective packing of tubes.	F1. Leaks caused by perishing of the packing material, especially in acid water. F2. Collapsing of tube.	F1. Varies. F2. Varies.	F1. Use good tape packing. Red lead is sometimes useful to prevent leakage. F2. Do not crush tube when inserting it.
G. Physically bad surface of tube; *e.g.* bad spills and laminations.	G1. Foreign bodies caught and trapped which would otherwise be swept away.	G1. Complete corrosion and oxide dezincification.	G1. During manufacture.
H. Thermo-electric action in condenser.	H. By steam impinging directly on tubes, or being improperly distributed.	H. Dezincification.	H1. Only occurs in condensers of old design when steam is not properly distributed.
I. Too slow water speed.	I. Gases given off inside tube and not immediately swept away.	I. Complete corrosion near inlet end.	I. Increase speed of water. Do not use main condenser for auxiliary machinery import.

Relation of Hardness to Tensile Tests.—Results of 114 tests on "smokeless-barrel steel" used in light Browning rapid-fire guns (C, 0.50 to 0.60 per cent; Mn, 1.15 to 1.30; Si, 0.18 to 0.25; P, 0.08 max.; S, 0.06 max.; ultimate 110,000; yield 75,000; reduction 40 per cent, elongation 20 per cent in 2 in.) are graphically tabulated by PROF. W. K. SHEPARD of Sheffield Scientific School in *American Machinist* for Apr. 17, 1919, p. 739. Inspection of the results shows that all specimens attaining the yield point had an ultimate strength of 115,000, while a reduction of 45 per cent would have agreed better with the 20 per cent elongation specification. Scleroscope tests fail to show any indication of low elongation, while the Brinell number between 255 and 269 shows a proper yield point and ductility. While the author does not advocate the replacement of tensile with hardness tests, he points out that inferior material can be easily located with a Brinell machine.

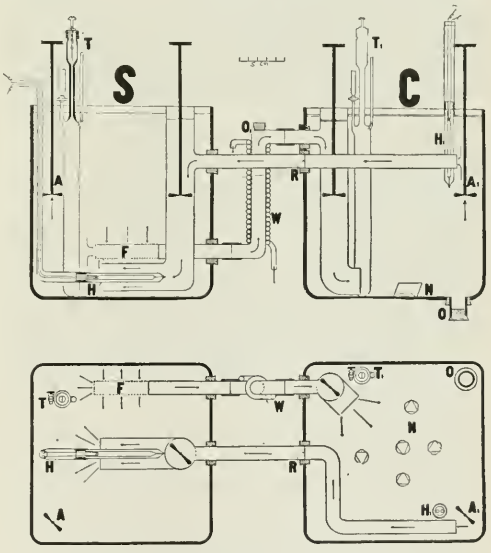
Tungsten in England.—JULIUS L. F. VOGEL, the metallurgist who founded the British tungsten industry, read a paper at the British Science Guild Exhibition on Aug. 30, 1918 (republished in the *Mining Magazine* for Jan., 1919), in which he reviewed the past and present situation of tungsten in England. He noted that Samuel Osborn & Co. of Sheffield made Mushet steel containing 6 to 8 per cent W for many years following its first use in 1857. The process consisted of reducing pure ore in a crucible of blister steel with an excess of carbon. F. W. Taylor's American researches caused an enormous advance in the use of high-speed steel, limited only by the gradual replacement of old machines insufficiently strong to take heavy, rapid cuts. Taylor and White's patents, by the way, were not upheld in England, and the larger production of high-tungsten alloys demanded a very pure alloying element, free from impurities omnipresent in wolfram (hubnerite, ferberite, etc.) such as Sn, Ca, As, S and P. At first a ferrotungsten of from 40 to 60 per cent was made in a crucible by carbon reduction, but the insistent demand for tungsten powder containing 95 per cent W and upward was met exclusively by the Germans, who were able to make 98 per cent metal with less than 0.5 per cent C. Hence grew the German monopoly of the European trade, despite several small-scale attempts in England to make tungsten powder.

On the declaration of war, England was left with a stock of but four months' normal consumption, and immediate conferences decided upon the stimulation of ore-production and local manufacture of high-grade tungsten powder. At the request of the Indian government a number of substantial Indian merchants took up and explored concessions in the recently opened Burmese districts. These men equipped mines and furnished transportation, resulting in largely increased production, but naturally at high cost. In many cases large sums were spent from which no return is likely.

English firms which collectively used some 80 per cent of the British consumption also immediately formed the High Speed Steel Alloys, Ltd., and by July, 1915, their factory at Widnes was delivering 98.5 per cent metal under the direction of the author. Their plant is substantially built, and is really but an enlarged laboratory. Fine ground ore is mixed with soda and fused, the cake crushed and boiled with water. Tungstate of soda goes into solution, while the insoluble basic oxides are filtered out. Pure tungstic acid (WO_3) is precipitated by HCl, filtered, dried, and reduced to metallic powder in special furnaces. Finally, the furnace product is washed and dried before packing.

Other companies have also entered this field, such as the Thermo-Electric Co., Blackwells, Continuous Reduction Co., British Thermit Co., Newcastle Alloys Co., Tyneside Alloys, and Albright & Wilson. Three of these use chemical processes similar to that at Widnes, two make ferrotungsten in an electric furnace, and three by aluminothermic methods. English makers of tool steels prefer the tungsten powder for its greater purity, although with pure ores, properly operated thermal processes will make a ferrotungsten which can be successfully employed in making high-speed steel.

Growth of Crystals.—The Feb. 19, 1919, issue of the *Journal* of the Washington Academy of Sciences contains an illustrated description of an apparatus used by J. C. HOSTETTER of the Geophysical Laboratory to form perfect crystals under controlled conditions for the study of strength, linear force of growing crystals, effects of non-uniform pressure on solubility, and effects of foreign substances in solution. While the apparatus has been used to study aqueous solutions, obvious modifications would permit the growth of substances of small solubility or from melts. The apparatus is shown in plan and elevation in the illustration, and consists essentially of two thermostats boxed together, the saturator *S* and the crystallizer *C*. By means of the thermostat *T* operating through relays the candle lamp *H*, *S* is maintained at a slightly higher temperature than *C* and is about ⅓ filled with large or bagged crystals. Saturated solution is drawn through gauze filter *F* into *C*, being directed against crystals *N*, placed on plane glass, and turned over daily. Volunteer crystals may be removed through *O*.



Perfect crystals require constancy in growth, which demands constant degree of supersaturation, constant temperature, uniform circulation, and a constant number of nuclei. The nuclei should be introduced at the start; they are small, well-formed crystals collected from a warm saturated solution allowed to cool overnight.

Recent Chemical and Metallurgical Patents

Buffer for Schoenherr Furnace.—JENS L. LA COUR, of Christiania, Norway, patents a buffer for nitrogen furnaces with long stable arcs under high gas pressure designed to minimize the effects of variations of gas pressure and velocity. It consists of a boiler (Fig. 1) mounted directly at the top of the tube-furnace *a*. Hot burned gases rising through *d* are partly cooled in the corrugated tube *c*, thence passing through the smaller tubes are drawn off the bottom of the casing. The steam pressure generated in this buffer-cooler is approximately equal to the gas pressure in the tube furnace, so that the metallic walls are under balanced forces. Such buffers may be placed in series, the first producing but a small decrease in temperature at the top of the flame tube in case the stability of the furnace action demands it. In any case, the buffer tube *c* being in line with the furnace *a* facilitates necessary variations in the end of the arc at *d* and equalizes pressure differences in the reaction chamber *a*. (1,296,194; assigned to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, of Christiania, Norway, March 4, 1919.)

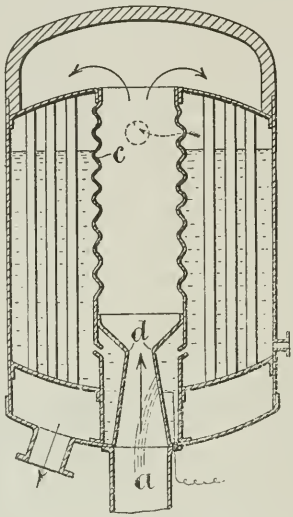


FIG. 1. BUFFER FOR NITROGEN FURNACE

Sulphonation of Aromatic Hydrocarbons

Aromatic Sulphonic Acids[1]—The counter-current principle has been applied to sulphonation by AMBLER and GIBBS. Sulphuric acid (sp.gr. 1.84), at a temperature above the boiling point of the hydrocarbon, flows down through a tower containing baffle plates, while vapors of the hydrocarbon are introduced at a point below the center of the tower. The process is continuous and, owing to the rapid removal of the sulphonated product, undesirable secondary transformations are practically eliminated. With toluene, monosulphonic acids are formed at 150 deg. C., while at 240-250 deg. C. the product is mainly toluenedisulphonic acid. (1,300,227 and 1,300,228; Apr. 8, 1919; dedicated to the public.)

Benzene Sulphonic Acids.—Benzene is passed into a still containing hot sulphuric acid (150-180 deg. C.) through a perforated ring below the surface of the acid. Unconverted vapors are condensed and returned to a storage tank. After a time, the speed of the reaction is greatly diminished, due to the dilution of the acid. When this point is reached (the ratio of free sulphuric acid to water in the mixture being 78 : 22) the system is evacuated by a suitable pump and the elimination of water vapor is facilitated by the stream of benzene vapor. By repeating these operations, a product containing over 90 per cent sulphonic acid and not more than 5 per cent free sulphuric acid may be obtained. This may be converted directly into the sodium salt without the necessity of first preparing the calcium salt. (1,301,360; ANDREW BENDER of Bogota, N. J., Apr. 22, 1919.)

Benzene Disulphonic Acid.—Another method for the production of sulphonic acids relatively free from excess sulphuric acid is described by CHARLES R. DOWNS of Cliffside, N. J. He has found that the mixture obtained by sulphonating hydrocarbons in the presence of excess sulphuric acid may be fractionally distilled under reduced pressure. With an absolute pressure of from one-half to one inch of mercury, water and free sulphuric acid may be removed from benzene disulphonic acid below 260 deg. C. without appreciable decomposition of the latter. Furthermore, during the distillation any monosulphonic acid present is converted into disulphonic acid, so that a very pure product is obtained. For the production of resorcinol this may be neutralized directly with soda ash, etc., and the solution added to the fusion pot without evaporating. (1,301,785; Apr. 22, 1919; assigned to The Barrett Co.)

Purification of Carbazol.—Commercial carbazol usually contains from 10 to 15 per cent of impurities (mainly anthracene), which yield sulphonic acids when treated with sulphuric acid even in the cold, whereas carbazol merely dissolves, provided the temperature is kept below 35 deg. C. The addition of water to the resulting solution precipitates carbazol which is 96 per cent pure and is almost entirely free from anthracene. By a single sublimation it gives substantially pure carbazol. (1,301,796; Apr. 22. 1919; JOHN M. WEISS of New York, assignor to The Barrett Co.)

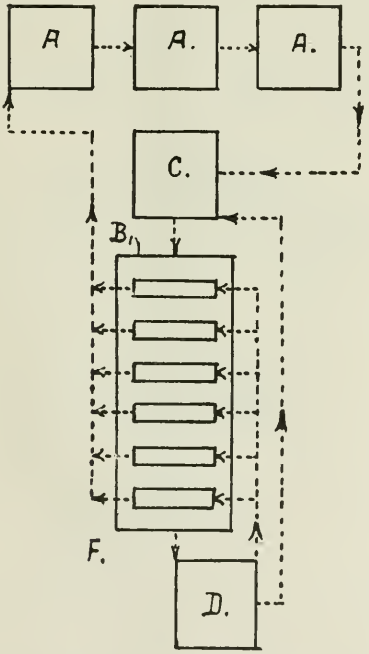
Iron for Precipitating Copper.—WOOLSEY MCA. JOHNSON of Hartford, Conn., suggests a method for preparing an efficient precipitation agent for the copper-bearing solutions in leaching processes. He transfers super-heated copper blast-furnace slag from an electrically heated settler into a long trough-like electric furnace. The reduction of iron oxide from such a slag is ordinarily slow, due to the fact that the surfaces in contact with the reducing agent are not sufficiently extensive to maintain a vigorous reaction. He, therefore, mixes the slag with pulverized coal by means of a number of jets of producer gas. The slag is thus progressively deoxidized as it passes along the long furnace, whose atmosphere at the same time is maintained sufficiently low in CO_2 that the electrode losses per ton of product will be moderate. As the slag flows toward the exit of this trough furnace and becomes lower in iron oxide, it comes in contact with a counter current of reduced iron having a lower and lower content of carbon and silicon. Thus metal quite low in these two elements may be tapped from the head end of the trough furnace, when it can be granulated or cast into such shapes as are desirable for use as a precipitating agent. The reduced iron oxide in the slag is replaced by hot quicklime, together with some fluorspar. (1,300,410; Apr. 15, 1919.)

[1] CHEM. & MET. ENG., Mar. 15, 1919, p. 282.

English Patents

Concentrating Ores.—In an agitation froth process for the preferential separation of one metalliferous mineral from another in a mixture containing them, for example a mixed sulphide ore, the agents employed are a soluble soap and sodium silicate in such proportions that a froth rich in one of the minerals is first obtained. After the froth has been separated the liquor may be diluted and re-agitated or aërated for the production of froth rich in another mineral. The ore is preferably treated in a freshly ground condition. (English Patent No. 121,303. E. EDSER, S. TUCKER and MINERALS SEPARATION, LTD., London, Eng., Feb. 5, 1919.)

Obtaining Metals Electrolytically With Circulating Electrolytes.—Granular Cu-Ni, Cu-Zn, or like alloys, obtained for instance by roasting and reducing matte, are treated with sulphuric acid, or other acid solution, until the acid is neutralized, and the solution is further treated with the same material to cement out the copper and produce a solution of nickel, zinc or the like for electrolysis. Mattes containing the two metals may be substituted for the alloy in the neutralizing



process. Air is introduced with the acid. From towers *A*, in which this treatment takes place, as shown in the illustration, the solution is run to a tank *C*, and thence to the cathode compartments of one or more electrolytic vats *B*. The solution is then conveyed to a tank *D*, whence most of it is returned to the supply tank *C*. The rest of this solution from the tank *D* is passed through the anode compartment *F*, the acid thus obtained being returned to the towers *A*. When two or more electrolytic vats are employed, the cathode compartments and the anode compartments may respectively be connected in series as regards liquid flow. Cathodes of iron and anodes of magnetite or hard lead may be used. The current density is 10 to 15 amp. per sq.ft. (English Patent No. 121,591. G. HAYLUND, Christiania, Norway. Not yet accepted. Feb. 12, 1919.)

Production of Ammonium Perchlorate and Sodium Bicarbonate.—Ammonium perchlorate is produced by reacting upon ammonium nitrate with sodium perchlorate in the presence of water. The precipitated ammonium perchlorate is separated and the solution of sodium nitrate is treated with ammonium bicarbonate or ammonia and carbon dioxide to cause the precipitation of sodium bicarbonate. The solution of ammonium nitrate after the removal of the bicarbonate is then used for reaction with a further quantity of sodium perchlorate. (English Patent No. 121,727—1918. D. AANENSEN, Christiania, Norway. Not yet accepted. Feb. 19, 1919.)

Acid-Proof Alloys.—Acid-proof alloys of iron and silicon containing not less than 13 to 15 per cent or more than 20 to 21 per cent silicon are made in a substantially pure state, preferably in an electric furnace. Pig iron may be melted with ferrosilicon and the impurities allowed to crystallize out of the molten mass, and a small amount of a flux, such as iron sulphide, may be added. Or iron or steel scrap may be melted with ferrosilicon, iron oxide being added when necessary to remove the carbon. The alloys may be used for making vessels for chemical manufactures and as anodes in electrolytic processes. (English Patent No. 121,730—1918. C. ROSSI, Legnano, Italy. Not yet accepted. Feb. 19, 1919.)

Reduction of Tungsten.—PETER ORANCE of New York City notes the difficulties inherent to properly mixing extraneous substances with tungsten oxides previous to their reduction, either by mechanical stirring of powders, by mixing into a paste, or by distillation of the body-material of a container. He proposes to obviate these by placing the tungsten oxide in a small closed shell capable of rotation, and during rocking of the vessel to blow into the mass heated air containing the addition agent, produced by volatilization from electrodes made of that material, by atomizing a solution, or by injecting a powdered material into the air blast. In this manner an intimate and uniform mixture may be had, which is then ready for molding into ingots prior to reduction, swaging and drawing, after the usual methods. (1,297,000; March 11, 1919.)

Improved Saggers.—F. J. TONE, of Niagara Falls, N. Y., has found that saggers or vats used to contain fine porcelains during firing are denser, stronger, more lasting and have a higher heat conductivity if containing a relatively high per cent of carborundum in addition to the usual clay grog plus plastic clay mixture. However, certain constituents of the clay or furnace gases alter the surface of the carborundum grains, which in turn produce a discoloration of the porcelain-ware contained in the sagger. The inventor finds that the action is confined to the surface of the grains, being limited to a thickness of from 0.0001 to 0.00001 cm., and therefore may be controlled by using relatively coarse carborundum (16 mesh) in moderate quantity—approximately 40 per cent of the mix. (1,296,715; asigned to Carborundum Co., March 11, 1919.)

Centrifugal Agitator and Distributor

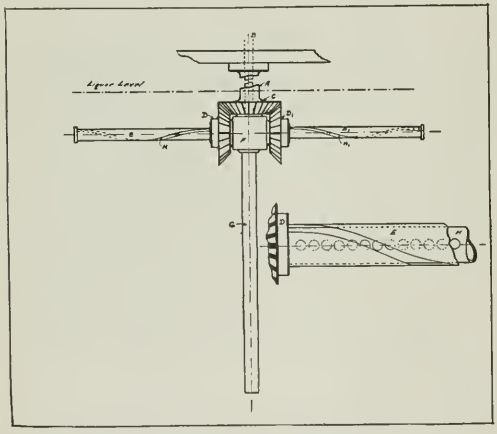
By Henry E. Jacoby

ONE of the simplest problems with which the manufacturing chemist has to contend, and at the same time one which often causes trouble and gives unsatisfactory results, is that of mechanical agitation. One reason for this is that so many operating men devise some crude homemade affair, putting a belt to it, and consider that all has been done that can be done in the way of getting satisfactory mechanical agitation.

The accompanying diagram shows the salient features of a device designed and patented by C. C. Thomas. One is immediately struck with not only the novelty of the mechanism, but also the basic principle which is applied. In general the device not only produces a mechanical stirring of the liquid or liquids in the containing vessel, the same as with the ordinary form of agitator, but at the same time produces a thorough vertical distribution of the material drawn to the vertex of the revolving liquid by means of a hollow vertical shaft.

The agitator is essentially a hollow tee which is supported by a suitable bridging or the cover of the tank, the upper part *A* being a hollow sleeve through which the vertical agitator shaft *B* passes. To the lower end of the sleeve *A* is attached a rigid bevel gear *C*, which meshes with the revolving gears *D* and D_1, the functions of which are to revolve the horizontal sleeve spiral distributors *E* and E_1 described below.

Part *F*, the head of the tee, is rigidly fixed to the solid agitator shaft *B* and revolves therewith. Attached to



MECHANICAL AGITATING DEVICE

the lower outlet of the tee is the vertical suction pipe *G*, and into each of the horizontal outlets are screwed the two horizontal arms *H* and H_1. These two horizontal arms *H* and H_1 are made up of wrought iron pipe perforated with a row of small holes for the liquid discharge. Sleeves *E* and E_1, which are rigidly attached to bevel gears *D* and D_1, are provided with a helical slot as shown in the diagram. The operation of the agitator is simple: The entire device being submerged in the liquid, the two horizontal arms *H* and H_1 are filled with the solution being agitated. As the device is revolved, no matter how slowly, there is sufficient centrifugal force developed in the arms to produce a flow of the solution in the arms toward the periphery. The solution so discharged is immediately replaced by liquid through the vertical suction pipe. The result is that even at very low speeds there is a circulation at once set up by liquid being forced from near the bottom of the containing vessel up and out through the revolving arms.

The function of the sleeves *E* and E_1 will not be apparent. As the agitator revolves, the bevel gears *D* and D_1, meshing with the rigid gear *C*, rotate. The result is that the helical slot in the sleeve will uncover successive discharge holes in the horizontal arms so that the point of the liquor discharge is continually traveling outward. The liquid is discharged at various points in a horizontal plane, and at continually varying distances from the center.

The results obtained by this device are really remarkable; not only is the distribution of the liquid beneficial, but the power required is remarkably small. It can readily be adapted to any existing tank, and will work successfully, not only on liquids of different densities, but will actually manipulate solid particles that are not too large to pass through the row of discharge apertures in the horizontal arms.

The apparatus has been tried out on a small scale for laboratory purposes, and has also been introduced into several manufacturing establishments, where it is giving excellent service. Its simplicity, as well as the excellent results obtained, should recommend it to all who have been on the lookout for an improved method of mechanical agitation.

Airtight Ashpit Door

CONSULTING engineers and architects are often required to draw detailed specifications for ashpit doors, because they have been unable to find a satisfactory standard piece of equipment. Contractors engaged in setting boilers are also often required to construct a steel door on the job because they had been unable to purchase a good door especially designed for the purpose.

The American Steam Conveyor Corporation, Chicago and New York, specializing in all forms of ash disposal, is manufacturing a door which has been produced as the result of careful tests and study, covering all points essential to successful operation and durability. It has been the experience of ash-disposal engineers that an ashpit door should be of ample size to allow easy removal of the ashes from the pit, but should not be unnecessarily large. If too large, it is impossible to keep the door from warping and thus leaking air, and it is also too heavy to be handled easily. A 24 x 36-in. door is ample for the largest pit, and this is the size recommended for ordinary use. Three other sizes of doors are also built of the same general design. These are in size, 18 x 18 in., 22 x 26 in. and 24 x 24 in.

The frame of the door is of cast iron of ample strength for all conditions, with the hinge and locking lugs cast on. The frame is of an angle design and sets well back into the setting. It is easily fastened into the pit wall by four bolts, one in each corner. The bearing surface is carefully machined. The hinge lugs are of ample strength to meet the hard usage to which these doors are subjected in operation.

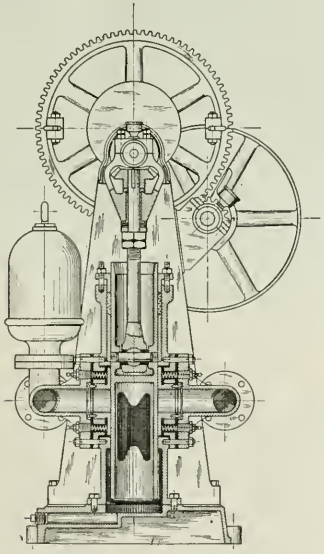
The door itself is of cast iron and is provided with a heavy ventilated cast-iron lining to prevent contact with the hot ashes and consequent warping. The bearing surface is carefully machined to make an airtight joint with the frame.

The hinges are of the floating type and two are provided. The hinge bars are pivoted to the frame and carry the door at the center where it is pivoted to the bars. This gives a perfectly distributed pressure over the door and keeps a tight joint at all points with no possibility of a clinker in the corner of the frame opening breaking or bending the door by a wedge action. It also allows the door to be swung entirely out of the operator's way.

Valveless Pump

THERE is no part of a pump exposed to greater wear than the rubber or other composition used in the valves on the water end. These valves, operating with every stroke of the pump, are not only subject to the continual pound as they open and close, but also have to stand the corrosive action of the fluid pumped. Different valves are required for different service—difference in pressure, difference in temperature of liquid, difference in nature of material pumped.

It is not easy to detect leaky pump valves, on account of their being closed, and a valve, after being in use a short time, may wear and suddenly break, putting a



SECTIONAL VIEW OF PUMP

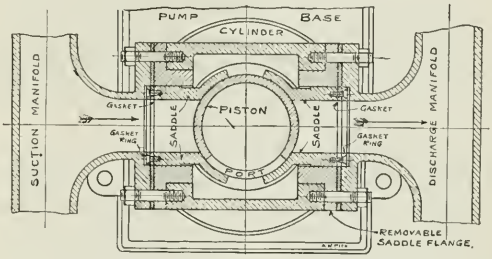
pump temporarily out of commission at a time when a shutdown for repairs means a considerable loss of time and money.

It might be said that the reputation of a pump depends more upon the quality and design of the valves than on any other part of the pump, because pump valves of a poor quality would seem to indicate poor material and workmanship in the pump itself.

Frequent failures of pump valves are often due to the fact that practically one class of pump valves are manufactured and sold for use in all kinds of service. Success under these conditions is practically impossible.

Further, all valves require for successful operation a special tension of valve springs, composition of rubber disc or metal seats. If these are not considered in the first place, the pump goes wrong, and the best pump is condemned as a failure. Tension of the spring is seldom adjusted evenly on all the valves, and those with the least tension are often to be the only ones that lift, thus defeating the object of multiple valves and greatly lessening the efficiency of the pump.

According to the best authorities, the friction of an ordinary check valve is equivalent to the frictional resistance of from 25 to 125 ft. of clear, straight iron pipe,



SECTIONAL PLAN THROUGH LINE OF SUCTION AND DISCHARGE, SHOWING SADDLES WITH PISTON AT END OF STROKE

varying according to the design, area of opening and tension of springs.

The renewal of valve parts is a continuous item of expense, and cannot be eliminated, unless you do away with valves. Ninety per cent of pump troubles are valve troubles. Ninety per cent of cost of upkeep of a pump is valve renewal cost.

Rotating Piston Pump

A new type of pump having a rotating hollow piston with a port simplifies the valve problem. The Dourte valveless pump, manufactured by the Mine & Smelter Supply Co. of Denver, has an exceptionally free passage for liquid into the cylinder when the suction is opened and a correspondingly free opening into the discharge, making it one of the best conveyors for liquids containing solids such as gravel, sand, sewage, pulp, coky pitches, etc.

The rotary movement of the piston is produced by a pair of miter gears one of which is keyed to the crank pin and the other to the end of the connecting rod. These gears are of equal size and number of teeth, therefore each complete revolution of the crank gives a corresponding revolution and stroke of the piston. With the crank at the extreme top or bottom, the piston is so placed that its port is not engaged with either suction or discharge opening, consequently all entries to the cylinder are closed.

On the upstroke the port in the piston is in connection with the suction opening, the discharge opening being closed or blanked by the wall of the piston. On the downstroke the situation is reversed, the port being in connection with the discharge opening while the suction opening is closed.

Referring to the illustrations, it will be noted that the piston is at the downstroke and the port neutral, being engaged with neither the suction nor discharge openings. As the piston rotates and advances upward spirally, the port engages with the suction or discharge openings, as the case may be.

The pump can be operated with equal efficiency in either direction, as reversing the direction of rotation

automatically reverses the flow of material through the pump. This feature is invaluable where it becomes necessary to clear the suction pipe, or where it is desirable to reverse the direction of flow, as in mixing tanks; thus the necessity of having a complicated arrangement of by-passes or a duplicate piping system is entirely eliminated.

The piston is a hollow casting open at both ends and is divided by a cross web near the center. The upper portion of the piston holds the connecting rod end by a universal joint, and the hollow receptacle here is of sufficient depth to contain the lubricant in which all the working parts are submerged, insuring perfect lubrication. The lower part of the piston contains a single port which alternately engages the suction and discharge openings on the side of the cylinder.

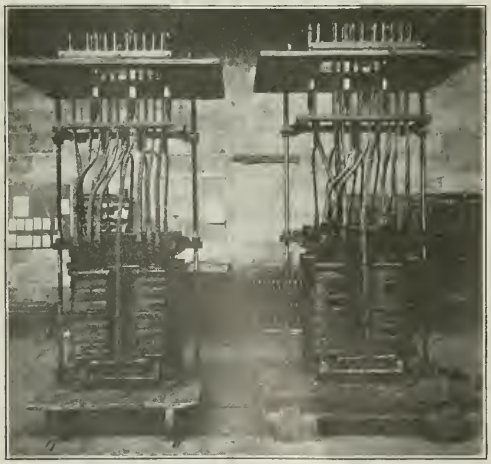
Transformers for Electric Furnaces

THE electric furnace owes its growing acceptance as a desirable medium both for heat-treating steel and melting non-ferrous metals chiefly to the more exacting control that it offers over furnace conditions. To supply an important link in the control equipment of its Baily electric furnaces, the Electric Furnace Co. of Alliance, Ohio, is building special transformers of the type illustrated.

These core type transformers are 400 k.v.a. capacity, and the high tension side, fitted with the usual voltage taps, is wound for 22,000 volts. The low tension side is fitted with ten special voltage taps to meet the particular voltage requirements of the furnace. Each transformer is single phase, and for small furnaces, requiring 100 kw. or less, one transformer is sufficient. Three-phase current is taken care of by two transformers fitted with a Scott connection. By means of the special low tension voltage taps, any desired current input may be delivered to the furnace through the selective oil break switches that are a part of each installation. With furnace current under control, any furnace temperature may be steadily maintained.

The transformers illustrated have just been shipped to the Braeburn Steel Co., Braeburn, Pa., as an accessory of a large 800-kw. continuous recuperative electric furnace that will be used to anneal alloy steel bars and wire. This special alloy requires a slow heating, lengthy soaking at maximum temperature, and cooling at a slow rate for the first 200 to 300 degrees.

This installation is of special interest, for although the usual annealing box covers are not used, scaling is entirely eliminated by this new method of electric annealing.

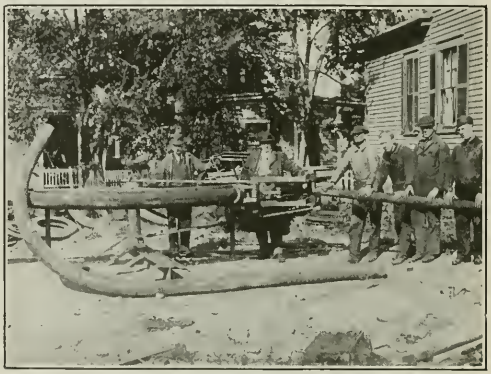


TRANSFORMER FOR ELECTRIC FURNACE

Pipe Bending Machine

SEVERAL models of portable pipe bending machines designed to handle from ⅜-1 in., ⅜-2 in., 1¼-4 in., and 3-8 in. pipe are manufactured by the American Pipe Bending Machine Co. of Boston. The machines are all of rigid construction, simply designed, and all parts interchangeable. An important feature is that they are all portable and may be knocked down and set up in a few moments.

A brief description of the machine will show its simplicity. The different machines have a central head suitably supported either for bench work, as with the Model S, or to be arranged with pipe legs in the larger models, A and B. On this head is mounted the interchangeable former-segments, and swiveled on the head is an arm on which is an adjustably mounted pin. On this pin is journaled a lever, on one end of which is swiveled a shoe of the proper size to fit the pipe to be formed. On the other end of the lever a pipe may be slipped to give sufficient leverage to bend the pipe, and the swinging arm is moved step by step as the pipe is bent, until the final bend is completed.



HERCULES PIPE BENDING MACHINE

The large model, or Hercules machine, is operated on a similar principle with improvements to give greatly increased power.

British Import Restrictions

The importation of the following commodities is prohibited except under special license:

Potassium salts, as follows: Bicarbonate, carbonate, chlorate, perchlorate, chloride (muriate), chromate and bichromate, cyanide, ferrocyanide (yellow prussiate), hydrate (caustic), nitrate, permanganate, sulphate, including potassium alums and potash manurial salts and mixtures containing any of these substances. Also saccharine and mixtures containing saccharine and other substances of like nature and use.

Pershing Commends Chemical Warfare Service

AMERICAN EXPEDITIONARY FORCES
Office of the Commander-in-Chief
March 2, 1919.

Col. Edward N. Johnston,
Chief of Chemical Warfare Service,
American E. F., Tours.

My dear Colonel Johnston:—Now that active operations have ceased and many of the personnel of the Chemical Warfare Service are returning to the United States, I desire to express to you and through you to all of your officers and enlisted men my appreciation of the valuable assistance they have rendered to the American Expeditionary Forces.

Upon our entry into the war we were faced with the problem of a new service in the organization of which the experience of our Allies was so new and so limited that there were few precedents to follow. The best brains and experience among our students and teachers of chemistry were called into service, and by rapid establishment of gas schools and the aid of specially trained personnel, all combat troops were instructed in the necessary defensive measures against poisonous gas. The first gas regiment was trained and equipped, and rendered good service in the two American offensives of St. Mihiel and the Meuse-Argonne.

Due to the energetic co-operation of all ranks, much was accomplished in a very short time, for which it gives me great pleasure to extend to you all the thanks of your comrades of the American Expeditionary Forces Will you convey this especially to Brigadier-General Fries, whose enthusiasm and energy were such great factors in the successful organization and development of the service.

Sincerely yours,
JOHN J. PERSHING.

Water-Resistant Glues

WATER-RESISTANT glues are of two general types, those made from blood albumen and those made from casein. All blood albumen glues are made directly from the raw ingredients at the time the glue is to be used. The manufacturers using these glues make them by their own secret formulas, and there are no published formulas available. Casein glues are made from casein, which is obtained from milk. They can be obtained in the prepared state ready for mixing with water, or they can be made directly from the ingredients at the time the glue is to be used.

The following prepared casein glues are now on the market: Certus glue, Certus Cold Glue Co., 88 Isabelle St., Detroit, Mich.; Napco glue, the Napco Corporation, Indianapolis, Ind.; Casco glue, Casein Mfg. Co., 15 Park Row, New York City, N. Y.; Perkins waterproof glue, Perkins Glue Co., Lansdale, Pa.

Directions for mixing the prepared glues can be obtained from the respective manufacturers or from the Forest Products Laboratory, Madison, Wis.

The water-resistant qualities of casein and blood glues are well demonstrated by the acceptance test imposed on plywood manufactured with these glues for use in aëroplanes. Samples of the plywood are boiled in water for 8 hours or soaked in cold water for 10 days. An acceptable product will show no separation of the plies under such treatment.

The shearing strength of casein and blood glues in plywood for aëroplane use is required to be at least 150 lb. per sq.in. Most of the plywood tested at the Forest Products Laboratory showed values considerably higher than this minimum requirement. In general, veneer panels glued with blood glue show higher average strength under the varying conditions than those glued with casein glues. It seems possible, however, that casein glues will in time be developed which will be the equal of blood albumen glues in this respect.

Both casein and blood glues are materially weaker wet than dry. Casein glues tested wet commonly have 20 to 40 per cent of their dry plywood shear strength, and blood glues 50 to 75 per cent. When plywood using these glues is redried after being soaked, however, the original strength of the glue is very largely recovered.

Blood glues are not at present commonly used for gluing anything thicker than veneer. Casein glues are used for gluing all thicknesses. Casein glue test joints, using blocks of maple with the grain running in the same direction, commonly have a shearing strength of 2000 to 2500 lb. per sq.in.

Blood albumen glue joints must be made with a "hot press" (having hollow plates heated with steam); a few minutes pressure is sufficient. Casein glue requires only an ordinary press, such as is used, with or without retaining clamps, for animal and vegetable glues.

The spreading equipment used for vegetable glues is suitable for both casein and blood albumen glues.

A mixer similar to the cake dough mixer used by bakers, consisting of a can in which a paddle revolves at high speed, is suitable for mixing casein glues. Blood albumen glues are mixed in different ways according to the requirements of their secret formulas.

Book Reviews

ELECTRO-ANALYSIS. By *Edgar F. Smith.* Sixth edition, revised, enlarged, 47 illustrations, xiii +344 pages, octavo. Philadelphia: P. Blakiston's Son & Co.

Analytical chemists and electrochemists in general owe Dr. Smith sincere appreciation of this careful revision of his indispensable book. Originally valuable because of containing the author's first-hand account of his contributions to this subject, the successive editions have grown, by careful condensation of the literature of the art, until it is a nearly complete handbook. Not only is the analytical chemist helped along, but the electroplater, the metal refiner, the electrometallurgist extracting metals from solutions, the electrochemist seeking new ways of coloring metals or of producing metallic compounds electrolytically, and yet other workers in electrolysis, can all find aid and comfort and generous assistance in studying its pages. The separation of the alkali metals in an improved "double cup" apparatus is an important item of novelty in this edition.

J. W. RICHARDS.

* * *

THE HYDROGENATION OF OILS, CATALYSIS, GENERATION OF HYDROGEN AND OXYGEN. By *Carleton Ellis, S.B.* Second Edition, thoroughly revised and enlarged, 767 pages, 240 illustrations. New York: D. Van Nostrand & Co.

The chemical and legal professions, at least those among them interested in the above subject, owe Carleton Ellis a debt of gratitude for his painstaking work in bringing together so many facts pertaining to the art of hydrogenation. He has succeeded remarkably well in giving the his-

tory of the subject from its beginning down to date, with descriptions of the very many processes described in patent and other literature, with full references, which makes the book exceedingly valuable to those interested in the patent side of the subject, while the very full accounts of the important litigations which have taken place add greatly to the interest from a legal standpoint.

The chapters on catalyzers are full of interest and present very fully in a compact form most all that has been written on the subject. The chapters on the uses of hydrogenated oils contain much valuable information, giving among other things a considerable insight into the lard-compound industry. A very useful chapter is the one on analytical constants, which presents in a compact form most everything which we have seen published. Those engaged in work on petroleum oils will find the chapter devoted to that subject very useful. The portion of the book describing the manufacture of hydrogen, covering 165 pages, would make a complete reference book by itself. The book taken as a whole is one which chemists and others connected with fat industries can hardly afford to be without.

DAVID WESSON.

* * *

COMMERCIAL OILS, Vegetable and Animal, With Special Reference to Oriental Oils. By *I. F. Laucks*. New York: John Wiley & Sons. 138 pages, inc. index.

This book, as stated in the preface, "is intended primarily for the non-technical man in the oil trade. The writer has attempted to give in it the technical data and information required in everyday dealings in the oil trade without mixing in a great mass of more or less scientific matter." The book contains trade rules and specifications wherever they may apply to the oils mentioned, besides giving conservative analytical constants. It is of particular value at this time, as it gives in a very compact form much information regarding various Oriental oils which are being imported at Pacific Coast points. There are tables showing properties of less common oils, together with comparison tables of hydrometers and thermometers. Last, but not least, is a very comprehensive index. DAVID WESSON.

Personal

DR. R. F. BACON, director of the Mellon Institute, is chairman of the committee of the American Institute of Chemical Engineers which is co-operating with the Government in the disposition of chemical plants and surplus stocks of chemicals and apparatus.

MR. H. FOSTER BAIN, who has served as assistant director of the Bureau of Mines through the war period, has resigned to resume exploration in the Far East. He sails from Vancouver June 12.

DR. JOHN S. BATES, who for several years has been superintendent of the Dominion Government Forest Products Laboratories in Montreal, Can., has resigned to take a position with Price Bros. & Co., of Quebec.

COL. G. A. BURRELL, Pittsburgh, Pa., has been given the degree of Doctor of Science by Wesleyan University, Middletown, Conn. Last year his alma mater, Ohio State University, gave him the honorary degree of Chemical Engineer.

MR. J. J. CADOT, recently returned from military duty in France, has accepted a position with the Hardinge Conical Mill Co., at the Denver, Colo., office.

MR. E. H. CLAUSSEN, recently discharged from military service, is with the Mine & Smelter Supply Co., at 42 Broadway, N. Y.

MR. THOMAS E. FISHER has resigned from the Wharton Steel Co. and become connected with the Traylor Engineering & Manufacturing Co. of Allentown, Pa.

GEN. GEORGE W. GOETHALS, best known as the builder of the Panama Canal, was presented with the John Fritz medal at the Engineering Societies Building, New York, on May 22.

MR. ELLWOOD HENDRICK, consulting editor of CHEMICAL & METALLURGICAL ENGINEERING, delivered the last lecture of a course before the Chemistry Club of the College of the City of New York on May 23, on "Some Chemists I Have Known." A large audience was present and listened to Mr. Hendrick's reminiscences and comments on Victor Meyer, Theodore W. Richards, Charles F. Chandler, Leo H. Baekeland and Irving Langmuir.

MR. R. W. HOVEY of the Forest Products Laboratories of Canada has resigned to accept a position with the Abitibi Power & Paper Co., at Iroquois Falls, Ont.

COL. DOUGLAS I. MCKAY has been elected president of the Pulverized Fuel Equipment Corp., New York, to succeed MR. JOHN E. MUHLFELD, who retires to return to consulting engineering practice.

MR. JOHN W. MALLER, until recently with W. R. Grace & Co., New York, has been appointed manager of the South American branch of the Ingersoll-Rand Co., with offices at Calle Merced 620, Lima, Peru.

MR. STUART B. MARSHALL, consulting engineer and metallurgist, has established his headquarters at Chevy Chase, Washington, D. C. He also retains his Roanoke, Va., address.

MR. CHARLES E. SHOLES has resigned from the Grasselli Chemical Co. to become vice-president and sales manager of the Edison Storage Battery Co. of Orange, N. J.

CAPT. EDWARD STEIDLE has recently returned from Europe to resume his work with the Carnegie Institute of Technology, Pittsburgh, Pa. He will devote his time to the development of a mining department which will be in close contact with the industry.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, May 24. — Prices have tended to advance sharply with the prospects of an active market in sight.

Aluminium:—The open market is nominal at 33c. Sheets 18 gage and heavier, 42c. Powder, $0.70-$1.40 lb.

Antimony:—Antimony has advanced sharply with silver. Spot, 7⅞c. to 8⅛c. lb.

Copper:—An advance in price is now taking place with spot at 16½c. and futures higher.

Copper sheets, hot-rolled	lb.	$0.22½ —	.....
Copper sheets, cold rolled	lb.	.23½ —	.....
Copper bottoms	lb.	.23½ —	.....
Copper rods	lb.	.19½ —	.....
Copper wire	lb.	.17½ —	$0.18
High brass wire and sheets	lb.	.18½ —	.....
High brass rods	lb.	.17½ —	.....
Low brass wire and sheets	lb.	.18½ —	.....
Low brass rods	lb.	.21½ —	.....
Brazed brass tubing	lb.	.29½ —	.....
Brazed bronze tubing	lb.	.33½ —	.....
Seamless copper tubing	lb.	.28 —	.....
Seamless bronze tubing	lb.	.29½ —	.....
Seamless brass tubing	lb.	.30 —	.....
Bronze (gold) powder	lb.	1.00 —	.....

Lead:—Lead is rising. New York asks 5¼c. and East St. Louis 5c. lb. Sheet lead, 8c.

Tin:—Tin remains at 72½c.

Zinc:—Spelter has become firmer, advanced to 6.6c. to 6.75c. in New York and offers no low priced futures. East St. Louis quotes 6¼c. Zinc dust, 10c. Sheets, 12c.

OTHER METALS

Bismuth	lb.	$3.20 —	$3.65
Cadmium	lb.	1.40 —	.....
Cobalt	lb.	2.50 —	3.50
Magnesium	lb.	1.75 —	2.10
Mercury	75 lb.	92.00 —	.....
Nickel	lb.	.40 —	.45
Tungsten	lb.	Nominal	
Iridium	oz.	175.00 —	.....
Palladium	oz.	115.00 —	120.00
Platinum	oz.	105.00 —	.....
Silver	oz.	1.06½ —	.....

The Iron and Steel Market

Developments in the iron and steel trade are being watched with much more interest than their intrinsic importance would merit, because knowledge of trends is desired. Since the signing of the armistice and the termination of war work not one single thing has occurred

in the iron and steel market that would furnish of itself an accurate guide to the future. For instance, last December certain price reductions occurred, but that did not prove that other declines were to occur, at either regular or irregular intervals, and the same observations apply to the reductions that occurred in March. Each decline in the market occurred with a particular stage setting, but that was not significant.

The latest development in the steel situation is the increase in buying that began about the middle of May. In point of volume the increase is not of much importance. At some periods in steel market history such an improvement would be accepted as indicating a definite trend. The conclusion would be reached that business was improving, and further improvement would be awaited with confidence. In this case, however, the character of the buying is what must be scrutinized, rather than the quantity, and its relation to the old orders with which some producing interests were well fortified at the war's ending, and which have been gradually playing out, must be considered.

Character of the Buying

As to the character of buying, it is observed that it is the same as formerly obtained. The orders come from the same classes of buyers, jobbers and ordinary manufacturing consumers. There is little buying for strictly new construction purposes. The increased buying does not represent greater "confidence" in the market, for the buyers are making purchases, as formerly, only for immediate delivery, and even at that they frequently seek price guarantees, which as a rule they do not secure. The buyers are not stocking up. In some instances they may be enlarging their stocks, but not for the purpose of having larger stocks for the future; rather for the purpose of carrying on a larger volume of business at present. It may be that some increase in buying has been produced directly by the exhaustion of stocks carried at the end of the war. The country was not bare of steel then by any means.

The conclusion is that the common everyday needs of the people, in iron and steel, have increased in the past few weeks, and that new construction, on any large scale, has not commenced. As to the influence of the playing out of old orders, not enough time has elapsed to show what this increase in new buying means. The constantly decreasing steel production since the beginning of the year has been due to the gradual exhaustion of old orders. Month by month, for instance, the Steel Corporation's unfilled obligations have decreased, the losses being much greater than the new bookings, as shown by the fact that the loss each month has been much more than half the estimated shipments. The monthly report of steel ingot production has indicated steel mill operations, in proportion to rated capacity, as follows: January, 87 per cent; February, 85 per cent; March, 77 per cent; April, 65 per cent, and the indication has been that May would show about 55 per cent. Whether there is enough increase in new buying, in connection with this recent improvement, to counteract the influence of old orders being completed, is still to be disclosed.

New Construction

The construction firms and fabricating interests report that in the past few months they have figured upon large quantities of construction work, but practically no jobs of any magnitude have been authorized. The projects are not abandoned, simply deferred, and there is no definite information as to why the deferments have been made. The investors themselves would probably be unable to assign definite and clear-cut reasons, and they certainly could not make a precise statement as to the set of conditions under which, if developed, they would be willing to go ahead. The Bridge Builders' and Structural Society has reported lettings of fabricated steel jobs, in proportion to fabricating capacity, as follows: January, 12 per cent; February, 12½ per cent; March, 17½; April, 24½ per cent. Nothing more favorable can be said of these figures than that they show a trend in the right direction. The jobs let have all been small.

To engage the full capacity of the steel industry new construction in large volume is essential. More than half the steel normally passes into investment employment, and certainly no other alignment can be expected now, when steel making capacity is 40 per cent greater than in 1914.

Railroad Requirements

It is traditional in the steel trade that there cannot be a full demand for steel unless the railroads are active buyers. The proportion of the total steel produced that passes to the railroads has been overestimated for years, perhaps partly because of the survival of old concepts based on conditions in the 1880's, when there was so much new construction of railroads. As a rough generalization it may be suggested that for normal upkeep of railroads between 10 and 15 per cent of the total steel that can be made is required, while anything like an extensive program of railroad expansion and development would double the tonnage. Under the most favorable conditions the railroads might take 25 to 30 per cent of the total steel that could be produced. In the past it has been only when the railroads were taking large tonnages that the steel industry was really busy.

For the remainder of this year the railroads will require very little steel. Analysis of the 1918 rail production statistics indicated that the steam roads had about 1,400,000 tons for replacement purposes, and at the beginning of this year it is understood that there was about 1,200,000 tons due them on old orders. On May 23 the Railroad Administration placed orders for 200,000 tons of rails, this being the mouse that came forth when the labors of the Industrial Board were abandoned. The tonnages for last year and this are ample for necessary replacement purposes. The railroads could lay many hundreds of thousands of tons of rails in addition, slightly improving the permanent way, but that would be a luxury not to be thought of in present circumstances. As to other steel requirements, a careful canvass of the situation has recently been made, disclosing that by some redistribution of material the railroads can get along to the end of the year with little additional steel beyond what is in stock at one point or another, or on order, for car and locomotive repair and ordinary upkeep in other directions.

Prices

The steel producers show little disposition to depart from the prices that became effective March 21. They are educated to adhere to existing prices, whatever they may be, unless they can effect advances, for they have no means of making clear-cut reductions and adhering to the new prices with the same fidelity as they showed with the previous prices. As long as there is no definite prospect that a break in the market would result in filling the mills and thus paving the way for an advancing market again, the mills are likely to make every effort to maintain the present schedules. Whenever they become convinced that the time is ripe for the starting of a general buying movement they will probably let down the bars, since it is traditional that such buying movement can thrive only on an advancing market. If when the time comes the market will not advance from the existing level, it will be necessary to provide it with a level from which it will advance.

The Chemical Market

New York, May 28.

Most of the job lots which were dumped on the market as soon as the armistice was signed, together with the quantities of salvage goods offered by the Government, have been absorbed. Soon the manufacturers' influence should be felt in a strengthened market. Furthermore, with the Government inclined toward protection, manufacturers are encouraged to bend every effort to meet the foreign competition which will follow the signing of the peace terms.

Inquiries, both domestic and for export, appear to show some improvement. Instead of being mere requests for prices, the inquiries are beginning to have substance.

Although the quoted price on caustic soda has under-

gone no change a perceptible strengthening of the market is seen. This is attributed to the increased domestic consumption and the demand for export, which have exhausted the war stocks. Japan has been the heaviest buyer.

There is a good demand for acetic acid, much of it being sold for export. However, the large stocks held by producers do not seem to have been affected and this commodity remains weak.

Unrest has been generated in the potash market by the arrival last week of 4000 bags of raw potash salts from Alsace-Lorraine and by the anticipation of further shipments from there, together with probable shipments from Germany within a few months. However, it is believed in most quarters that the Government will take a hand in regulating Germany's shipments. One house reports a large shipment of caustic potash and potassium carbonate to Denmark.

Sodium bichromate is weak due to the reduction in cost of the raw material from which it is made. Sodium sulphide is active, South American demand being the reason. The manufacturers are still maintaining the price of 4⅜c. a lb. for it, but second hands are shading this to the export trade.

With the textile mills settling down to work again, there is a strong demand for oxalic acid. Largely to stimulate trade, formaldehyde has dropped to 20-21c. Increased commercial demand, together with the depletion of war stocks, has stiffened glycerine. The sale of a carload of dynamite glycerine at 20½c. caused a general advance to 21c. Oxide of tin remains lower in price owing to the low price levels of some of its substitutes.

Of particular interest is the proposed formation of a $15,000,000 export company to represent the leading chemical manufacturers of the country.

WAXES:—There is a good demand for waxes, particularly carnauba. Last week 4400 bags of carnauba were placed on the market, making a record stock. Yet in the face of this the price of carnauba rose. Paraffine waxes declined because of lessened demand and the fact that manufacturers, having large quantities on hand, desire to stimulate business. Japan wax is selling at a high mark owing to scarcity of spot stock and the high price of tallow, with which it is sympathetic.

COAL-TAR PRODUCTS:—No increased activity among any of the crudes is noted; intermediates, however, are beginning to pick up. From all quarters comes the report that both domestic and export inquiries are improving. The export phase is hampered by the inability to procure shipping space.

OILS:—Vegetable oils show great activity with rapidly advancing prices. The main factor is the heavy export demand caused by the dearth of fats in Europe. Demand for all the vegetable oils has depleted stocks, resulting in a speculative market. The top price has not been reached.

In spite of a decline in linseed oil, due to smallness of demand, it is predicted that the short supply of seed will soon cause prices to soar.

SHELLAC:—Stocks of shellac are the lowest they have ever been, while prices are the highest ever attained in the history of the trade. There are practically no spot stocks of any grade. Of TN, the shellac on which the price of all the other grades is based, none is to be had at any price. The same is true of the other grades, with the exception of orange, fine, super-fine and A.C. garnet. The supply of these is limited and will soon be exhausted. Consumers are willing to buy any grade and at any price.

In normal times the price of TN holds close to 38c. a lb., the highest being $0.638 in 1875, the lowest $0.088 in 1888. The present price is nominal, but the situation will improve as soon as an expected consignment from Calcutta arrives.

The present situation is due not to the scarcity in the supply of shellac in India, but rather to the policy followed by the consumers. They reasoned that with the embargoes imposed by the war and the dangers to shipping removed the market was certain to decline. The market did decline and the buying was for immediate needs only. At the same time, while buying continued on this basis, dealers did not care to assume the risk of carrying surplus stocks. Then the market began to rise due to scarcity of spot stocks with the result that consumers rushed into the market and dealers had not enough stock on hand to supply the sudden demand.

Chicago, May 24.

Trade conditions in chemical lines continue to register the improvement indicated the first part of this month. With second hand stocks becoming materially reduced and nearly all prices either showing a slight advance or remaining firm, the tendency of buyers is toward longer term buying. The stabilizing market has caused buyers to seem more satisfied with dealers' offerings, and reflects generally a much more satisfactory condition than obtained during the preceding four months.

Jobbers state that gross sales are larger for May than in the corresponding month last year, yet still under those of last fall. With collections good a decidedly optimistic tone is noted.

Heavy chemicals are having a very slow recovery, caustic soda and bleach still being weak, but soda ash in fair demand with the price firm. Few changes in acids are noted, demand more nearly approximating supply than in the recent past. Carbolic is finding a fairly ready sale at 9 cents.

No price differences have developed in coal-tar products, benzol standing at 25c. No particularly large contracts have been noted, sales of small lots being the feature of the market, the movement being sufficient to prevent any accumulation of overstock.

The previously noted good market in vegetable oils is still in effect, with every indication of long continued similar conditions. The recent destruction of the Douglas Starch Works at Cedar Rapids, Iowa, by an explosion which was fatal to a large number of men, involved the loss of quantities of corn oil, and is having an immediate effect of further stiffening prices in this entire line.

Naval stores and flotation oils continue in excellent demand. No appreciable price changes are noted.

St. Louis, Mo., May 26.

A decided improvement in most branches of the heavy chemical market at St. Louis is reported by producers and traders to have manifested itself within the last week or two. Sulphuric acid, especially, the key item of the heavy chemical market, was more sought for than at any time since the signing of the armistice, it is reported.

Both inquiries and actual sales are more frequent and of heavier volume now than for many weeks. The revival in trading in the acids has given a firmer tone to the chemical market generally. The business of the last week, well informed men say, represents no mere temporary spurt of buying, but an actual resumption of activities in certain industries that have been very quiet or at a standstill since the cessation of hostilities.

Sulphuric Acid: — Of 60 degrees, a large supply is on hand. Comparatively heavy sales are reported for the last fortnight at around $12.50 a ton; 66-deg. acid is quoted at $18 a ton.

Muriatic Acid:—A fair business is being done in this line, producers say, and inquiries are increasing; $22 a ton for 18-deg. is quoted.

Nitric Acid:—This branch of the market remains stationary; very little trading is in progress and the price remains unchanged at 9½c. per pound for 38-deg.

Zinc Chloride:—A very good demand for this chemical is apparent here. It seems that the Railroad Administration is giving the creosoting people a good deal of work and this is being reflected in an increased demand for zinc chloride. The prevailing quotation is 4½c. per pound.

Sodium Sulphate:—Salt cake is quoted at $20 a ton and is in better demand than for some time in the past.

Sodium Bisulphate:—Niter cake is quoted at $3 a ton, with no demand at present, as the glass-manufacturing season does not open until Aug. 15. It is expected, from the character of present inquiries for this item, that business will be resumed about July 1.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET MAY 28, 1919

Acetic anhydride	lb.	.54 —	.60
Acetone	lb.	.15 —	.15½
Acid, acetic, 28 per cent	cwt.	2.50 —	3.00
Acetic, 56 per cent	cwt.	5.50 —	6.00
Acetic, glacial, 99½ per cent, carboys	cwt.	12.00 —	14.00
Boric, crystals	lb.	.13½ —	.14½
Boric, powder	lb.	.13½ —	.14½
Hydrochloric, tech. 20 deg.	cwt.	1.50 —	3.00
Hydrofluoric, 52 deg.	lb.	.08 —	.09
Lactic, 44 per cent, tech.	lb.	.14 —	.17
Lactic, 22 per cent, tech.	lb.	.05 —	.06
Molybdic, C. P.	lb.	6.50 —	7.40
Nitric, 40 deg	lb.	.07 —	.08
Nitric, 42 deg	lb.	.07 —	.08
Oxalic, crystals	lb.	.23 —	.28
Phosphoric, Ortho, 50 per cent. solution	lb.	.07½ —	.10
Picric	lb.	.75 —	.85
Pyrogallic, resublimed	lb.	2.50 —	2.55
Sulphuric, 60 deg., tank cars	ton	11.00 —	13.00
Sulphuric, 60 deg., drums	ton	17.00 —	.....
Sulphuric, 60 deg., carboys	ton	20.00 —	.....
Sulphuric, 66 deg., tank cars	ton	16.00 —	18.00
Sulphuric, 66 deg., drums	ton	21.00 —	.....
Sulphuric, 66 deg., carboys	ton	25.00 —	.....
Sulphuric, fuming, 20 per cent. (oleum) tank cars	ton	20.00 —	22.00
Sulphuric, fuming, 20 per cent. (oleum) drums	ton	25.00 —	.....
Sulphuric, fuming, 20 per cent. (oleum) carboys	ton	30.00 —	.....
Tannic, U. S. P.	lb.	1.30 —	1.40
Tannic, (tech.)	lb.	.42 —	.60
Tartaric, crystals	lb.	.82 —	.85
Tungstic, per lb. of WO_3	lb.	1.25 —	1.50
Alcohol, Ethyl	gal.	4.00 —	4.85
Alcohol, Methyl	gal.	1.25 —	1.30
Alum, ammonia lump	lb.	.04 —	.05½
Alum, potash lump	lb.	.08½ —	.10
Alum, chrome lump	lb.	.15 —	.....

Zinc oxide, dry American	lb.	.09½ —	.11½
Zinc sulphate	lb.	.03½ —	.04

Coal Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha nsphthol, crude	lb.	1.00 —	1.10
Alpha nsphthol, refined	lb.	1.40 —	1.50
Alpha nsphthylamine	lb.	.40 —	.50
Aniline oil, drums extra	lb.	.22 —	.24
Aniline salts	lb.	.28 —	.33
Anthracene, 80% in drume (100 lb.)	lb.	.90 —	1.00
Benzaldehyde (f.f.c.)	lb.	1.00 —	1.15
Benzidine, base	lb.	1.00 —	1.15
Benzidine, sulphate	lb.	.90 —	1.10
Benzoic acid, U. S. P.	lb.	1.00 —	1.10
Benzoate of soda, U. S. P.	lb.	.95 —	1.10
Benzol, pure, water-white, in drums (100 lb.)	gal.	.22 —	.27
Benzol, 90%, in drums (100 lb.)	gal.	.22 —	.27
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate	lb.	4 00 —	4 50
Beta naphthol, sublimed	lb.	.75 —	.80
Beta naphthol, tech	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2 25 —	2 35
Cresol, U. S. P., in drums (100 lb.)	lb.	.18 —	.....
Ortho-cresol, in drums (100 lb.)	lb.	.23 —	.25
Cresylic acid, 97-99%, straw color, in drums	gal.	1.00 —	1.02
Cresylic acid, 95-97%, dark, in drums	gal.	.90 —	.92
Cresylic acid, 50%, first quality, drums	gal.	.60 —	.....
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.75 —	2 25
Dimethylanilins	lb.	.50 —	.57
Dinitrobenzol	lb.	.25 —	.35
Dinitrochlorbenzol	lb.	.25 —	.28
Dinitronaphthaline	lb.	.45 —	.55
Dinitrotoluol	lb.	.38 —	.45
Dinitrophenol	lb.	.30 —	.32
Dip oil, 25% tar acids, car lots, in drums	gal.	.38 —	.46
Diphenylamine	lb	.70 —	.75
H-acid	lb.	1.90 —	2.25
Metaphenylenediamine	lb.	1.20 —	1.80
Monochlorbenzol	lb.	.13 —	.14
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline, crushed in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.07 —	.08
Naphthaline, balls	lb.	.10½ —	.11½
Naphthionic acid, crude	lb.	1.00 —	1.25
Nitrobenzol	lb.	.13 —	.15
Nitronaphthaline	lb.	.40 —	.45
Nitro-toluol	lb.	.17 —	.20
Ortho-amidophenol	lb.	6.00 —	.....
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	1.25 —	.....
Ortho-toluidine	lb.	.40 —	.45
Ortho-nitro-toluol	lb.	.35 —	.50
Paramsidophenol, base	lb.	2.75 —	3.50
Para-amidophenol, H. Cl.	lb.	3.00 —	3.25
Para-dichlor-benzol	lb.	.06 —	.10
Parasitraniline	lb.	1.10 —	1.25
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenedismine	lb.	3.00 —	3.25
Para toluidine	lb.	1.50 —	1.75
Phthalic anhydride	lb.	1.75 —	2.15
Phenol, U. S. P. drums (dest.), (240 lb.)	lb.	.08 —	09
Pyridin	gal.	$2.50 —	.....
Resorcin, technical	lb	3.50 —	3.75
Resorcin, pure	lb.	6.50 —	7.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.20 —	.30
Salicylic acid, U. S. P.	lb.	.25 —	.35
Salol	lb	.75 —	.85
Solvent naphths, water white, in drums, 100 gal.	gal.	.20 —	.25
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.18 —	.20
Sulphanilic acid, crude	lb.	.25 —	.30
Tolidine	lb.	2.15 —	2.50
Toluidine, mixed	lb.	.45 —	.80
Toluol, in tank cars	gal.	.22 —	.24
Toluol, in drums	gal.	.23 —	.30
Xylidine, drums, 100 gal	lb.	.40 —	.45
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal	gal.	.30 —	.40
Xylol, commercial, in tank cars	gal.	.30 —	.....

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	.39 —	.40
Beeswax, refined, yellow	lb.	.44 —	.47
Beeswax, white pure	lb.	.62 —	.65
Carnauba, No. 1	lb.	.80 —	.83
Carnauba, No. 2, regular	lb.	.65 —	.72
Carnauba, No. 2, North Country	lb.	.50 —	.55
Carnauba, No. 3, North Country	lb.	.42 —	.44
Ceresin, yellow	lb.	.16 —	.18
Ceresin, white	lb.	.18 —	.20
Japan	lb.	.14 —	.18
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.07 —	.08
Paraffine waxes, crude scale, 117-119 m.p.	lb.	.07 —	.08
Paraffine waxes, crude scale, 124-126 m.p.	lb.	.07½ —	.08
Paraffine waxes, refined, 118-120 m.p.	lb.	.09 —	.09½
Paraffine waxes, refined, 123-125 m.p.	lb.	.09½ —	.10
Paraffine waxes, refined, 128-130 m.p.	lb.	.09½ —	.10½
Paraffine waxes, refined, 130-132 m.p.	lb.	.10½ —	.11
Paraffine waxes, refined, 133-135 m.p.	lb.	.11½ —	.12
Paraffine waxes, refined, 135-137 m.p.	lb.	.12½ —	.13
Stearic acid, single pressed	lb.	.18 —	.19
Stearic acid, double pressed	lb.	.19½ —	.21
Stearic acid, triple pressed	lb.	.22 —	.24
Spermaceti	lb.	.30 —	.32

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lbs.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.		$0.68
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.		.45
Pine tar oil, ref., sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.		.33
Pine tar oil, double ref., sp. gr. 0.965-0.990	gal.		.58
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.		.38
Turpentine, crude, sp. gr., 0.900-0.970	gal.		.61
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.		.24
Hardwood oil, f.o.b. Mich., sp. gr., 1.06-1.08	gal.		.24
Pinewood creosote, ref.	gal.		.48

Naval Stores

The following prices are F.o.b., New York, for carload lots.

Rosin B-D, bbl	280 lb.	$12.00 —	$12.55
Rosin E-I	280 lb.	12.70 —	12.75
Rosin K-N	280 lb.	14.05 —	14.25
Rosin W. G.-W. W	280 lb.	15.05 —	15.60
Wood rosin, bbl	280 lb.	12.25 —	.....
Spirits of Turpentine	gal.	.81½ —	.78½
Wood Turpentine, steam dist	gal.	.75 —	.....
Wood Turpentine, dest. dist	gal.	.69½ —	.....
Pine tar pitch, bbls	200 lb.	8.00 —	8.25
Tar, kiln burned, bbl. (500 lbs.)	bbl.	12.50 —	13.50
Retort tar, bbl	280 lb.	13.50 —	14.50
Rosin oil, first run	gal.	.68 —	.78
Rosin oil, second run	gal.	.70 —	.80
Rosin oil, third run	gal.	.82 —	.83
Rosin oil, fourth run	gal.	.85 —	.95

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½
70-72 deg., steel bbls. (85 lb.)	gal.	.31½
68-70 deg., steel bbls. (85 lb.)	gal.	.30½
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls	lb.	$0.21 —	$0.23
Castor oil, AA, in bbls	lb.	.23 —	.24½
China wood oil, in bbls	lb.	.18 —	.21
Cocoanut oil, Ceylon grade, in bbls	lb.	.15½ —	.16
Cocoanut oil, Cochin grade, in bbls	lb.	.17 —	.18
Corn oil, crude, in bbls	lb.	.19½ —	.20
Cottonseed oil, crude (f.o.b. mill)	lb.	.17½ —	.17½
Cottonseed oil, summer yellow	lb.	.23 —	.25
Cottonseed oil, winter yellow	lb.	.24½ —	.25
Linseed oil, raw, car lots	gal.	1.56 —	1.58
Linseed oil, raw, tank cars	gal.	1.52 —	1.56
Linseed oil, boiled, car lots	gal.	1.58 —	1.60
Olive oil, commercial	gal.	2.10 —	2.25
Palm, Lagos	lb.	.15½ —	.18
Palm, bright red	lb.	.15 —	.16
Palm, Niger	lb.	.14 —	.15
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.19½ —	.22
Peanut oil, refined, in bbls	lb.	.22 —	.24
Rapeseed oil, refined, in bbls	gal.	1.50 —	1.55
Rapeseed oil, blown, in bbls	gal.	1.58 —	1.60
Soya bean oil (Manchurian), in bbls., N. Y.	lb.	.16½ —	.17
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.15 —	.16

FISH

Winter pressed Menhaden	gal.	$0.89
Yellow bleached Menhaden	gal.	.91
White bleached Menhaden	gal.	.93
Blown Menhaden	gal.	.99

Miscellaneous Materials

All Prices F.o.b., N. Y.

Barytes, domestic, white, floated	ton	$25.00 —	$36.00
Barytes, off color	ton	22.00 —	27.00
Blanc fixe, dry	lb.	.03½ —	.04½
Blanc fixe, pulp	ton	30.00 —	45.00
Casein	lb.	.16 —	.18
Chalk, English, extra light	lb.	.05 —	.07
Chalk, English, light	lb.	.04½ —	.06
Chalk, English, dense	lb.	.04 —	.05
China clay (Kaolin), imported, lump	ton	35.00 —	.....
China clay (Kaolin), imported, powdered	ton	60.00 —	.....
China clay (Kaolin), domestic, lump	ton	10.00 —	20.00
China clay (Kaolin), domestic, powdered	ton	25.00 —	40.00
Feldspar	ton	11.00 —	15.00
Fluorspar, acid grade, lump, f.o.b. mines	net ton	30.00 —	35.00
Fluorspar, acid grade, ground, f.o.b. mines	net ton	35.00 —	40.00
Fuller's earth, domestic, powdered	ton	30.00 —	40.00
Fuller's earth, imported, powdered	ton	..... —	.....
Pumice stone, imported	lb.	.03 —	.06
Pumice stone, domestic	lb.	.02½ —	.....
Shellac, TN	lb.	.60 —	.....
Shellac, D.C.	lb.	..... —	.....
Shellac, V. S. O.	lb.	..... —	.....
Shellac, Diamond I	lb.	..... —	.....
Shellac, orange, fine	lb.	.73 —	.....
Shellac, orange, superfine	lb.	.75 —	.....
Shellac, A.C. garnet	lb.	.63 —	.....
Shellac, bleached, bone dry	lb.	..... —	.....
Shellac, bleached, fresh ground	lb.	..... —	.....
Soapstone	ton	15.00 —	25.00
Talc, domestic	ton	16.00 —	60.00
Talc, imported	ton	55.00 —	60.00

Refractories

Following prices are f. o. b. works:

Chrome brick	net ton 90–100 at Chester, Penn.
Chrome cement	net ton 45–50 at Chester, Penn.
Clay brick, 1st quality fireclay	net ton 35–45 at Clearfield, Penn.
Clay brick, 2nd quality	net ton 30–35 at Clearfield, Penn.
Magnesite, dead burned	net ton 50–55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton 80–90 at Chester, Penn.
Silica brick	net ton 41–45 at Mt. Union, Penn.

Ferro-alloys

All prices f. o. b. works.

Ferro-carbon-titanium, 15–18%, f. o. b. Niagara Falls, N. Y.	net ton	$220.00 —	.....
Ferro-chrome, per lb. of Cr. contained, 6-8% carbon	lb.	.32 —	.40
Ferro-chrome, per lb. of Cr. contained, 2–4% carbon	lb.	.70 —	.....
Ferro-manganese, 70-80% Mn	gross ton	110.00 —	125.00
Spiegeleisen, 16-20% Mn	gross ton	40.00 —	50.00
Ferro-molybdenum, per lb. of Mo	lb.	2.50 —	3.00
Ferro-silicon, 50%	gross ton	90.00 —	115.00
Ferro-silicon, 75%	gross ton	150.00 —	175 00
Ferro-silicon, 10-15%	gross ton	45.00 —	60.00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	1.30 —	1.60
Ferro-uranium, 35-50%, of U	lb.	7.00 —	.....
Ferro-vanadium, 30-40%, per lb. of contained V	lb.	6.00 —	7.00

Resales and overstocks make above prices approximate.

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.70	
Chrome ore, 48% and over	unit	1.00 —	$1.25
Coke, foundry, f.o.b. mines	net ton	4.50 —	5.00
Coke, furnace, f.o.b. mines	net ton	4.00 —	5.00
Petroleum coke, f.o.b. Atlantic seaboard	net ton	16.00 —	16.50
Fluorspar, gravel, f.o.b. mines	net ton	18.50 —	20.00
Manganese ore, 45% Mn and over	unit	.50 —	.85
Manganese ore, chemical (MnO_2)	gross ton	60.00 —	70.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75 —	.85
Tungsten, Scheelite, 60% WO_3 and over per unit of WO_3	unit	9.00 —	10.00
Tungsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50 —	8.00
Uranium oxide, 96%	lb.	..... —	.....
Vanadium pentoxide, 99%	lb.	6.00 —	.....
Pyrites, foreign, lump	unit	.17 —	.....
Pyrites, foreign, fine	unit	.17 —	.....
Pyrites, domestic, fine	unit	.14 —	.....
Ilmenite, 50% TiO_2	net ton	30.00 —	.....
Rutile, 95% TiO_2	net ton	200.00 —	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	3.00 —	3.25

Resales and overstocks make above prices approximate.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without bags	bbl.	$2.30
Lump lime, common, including container	300 bbl.	2.65
Common brick, at dock	M.	15.00
Hollow building tile, { At factory, Perth Amboy, N. J., } 8x12x12	M.	194.40
	M.	291.60
Yellow pine, 3x4 to 8x8, 20-24 ft. long	M.	39.00
Yellow pine, 3x4 to 8x8, 20-24 ft. long at Chicago	M.	38.50
Yellow pine, 3x4 to 8x8, 20-24 ft. long at St. Louis	M.	35.00
Roofings, tar felt (14 lb. per 100 sq.ft.)	ton	50.00
Roofings, tar pitch (in 400-lb. bbl.)	ton	19.00
Roofings, asphalt pitch	ton	30.00
Roofings, asphalt felt	ton	65.00
Roofings, slate-surfaced shingles, per roll of 108 sq.ft.		2.10
Roofings, slate-finished shingles, 100 sq.ft.		5.50
Linseed oil, raw in barrels	gal.	$1.63
Linseed oil, 5 gal. cans	gal.	1.76
Red lead, dry, 100 lb. keg	lb.	.13
Red lead, in oil, 100 lb. keg	lb.	.14½
Red lead, dry, 5 lb. cans	lb.	.15
Red lead, in oil, 5 lb. cans	lb.	.16½
White lead, dry and in oil, 100 lb. keg	lb.	.13
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	.12½
White lead, dry and in oil, 5 lb. cans	lb.	.15

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in.	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.66
Rivets, structural, ½-in. and larger	100 lb.	4.20
Rivets, conehead for boilers, ½-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.35
Sheets, No. 10 blue annealed	100 lb.	3.55
Sheets, No. 28 galvanized	100 lb.	5.70

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

ALBANY—The Southern Cotton Oil Co., First National Bank Bldg., Montgomery, plans to increase the capacity of its mixing plant to 10,000 tons and build a gin with 72-bale capacity near the oil mill here. Estimated cost, $50,000.

Arizona

PHOENIX—The city has had plans prepared by H. Phillips, consulting engineer, International Life Bldg., St. Louis, Mo., for a gravity water supply from the Verde River, to include filtration system, 42-in. pipe line and 25,000,000-gal. concrete reservoir. Estimated cost, $1,350,000.

TUCSON—Hereford & Hubbard plan to install a 100-ton concentration float mill on the Bannet property.

California

BISHOP—A. D. Schiveley, city clerk, will receive bids until June 2 for the construction of a sanitary sewerage system and sewage treatment tank. Olmsted & Gillelen, 1112 Hollingsworth Bldg., Los Angeles, engineers.

EMERYVILLE—The Sherwin Williams Co., 454 2nd St., San Francisco, will soon award the contract for the construction of a 2-story paint and varnish factory on the old race track, here.

HUNTINGTON BEACH—The city plans an election soon to vote on $40,000 bonds for rebuilding its gas plant. Olmsted & Gillelen, Hollingsworth Bldg., Los Angeles, engineers.

Connecticut

HARTFORD—The city has awarded the contract for the construction of a filtration plant, to the Foundation Co., 233 Broadway, New York City, N. Y. Estimated cost, $627,507. Noted Mar. 1.

Illinois

CHICAGO—J. McGillen, clerk sanitary district, Room 700, 910 South Michigan Ave., has awarded the contract for the construction of the Des Plaines River sewage treatment works, Division A, sewage treatment plant, to Leyden-Ortseifer Co., 53 Jackson Blvd., $384,281; Division P, electrical equipment, to the W. A. Jackson Co., 37 West Van Buren St., $22,795; Division W, venturi meters, to the Builders Iron Foundry, 209 South La Salle St., $12,760.

ROCKFORD—A. C. Woods & Co., engineers, plan to build a fabricating plant here.

Indiana

WHITING—The Board of Public Works will receive bids until June 2 for building a water system: (a) mechanical water-filtration plant, gravity type, 4,000,000-gal. per day capacity, including aërating basin, coagulating basin, filters, reservoir, head house; making connections with the city mains and the erection of equipment specified in (b); (b) one 5,000,000-gal. centrifugal pump, two 5,000,000-gal. centrifugal pumps, one 3,000,000-gal. centrifugal pump, two 3,000,000-gal. centrifugal pumps, one wash water pump, and one switchboard and equipment. Work under (a) includes 6,000 cu.yd. excavation and 440,000 lb. reinforcing steel. S. A. Greeley, 39 West Adams St., Chicago, Ill., engineer.

Iowa

ALTA—The city has awarded the contract for the construction of a sewage disposal plant, to Ward & Weighton, 516 Davidson Bldg., Sioux City. Estimated cost, $12,740.

AURELIA—C. H. Currie, engineer, Webster City, will receive bids until June 3 for the construction of a sanitary sewer and a sewage disposal plant. Estimated cost between $30,000 and $40,000.

GARNER—The city will receive bids until June 4 for the construction of a sanitary sewerage system and sewage disposal plant to include (a) disposal plant, tank, sand filters and sludge bed, (b) cutlet main sewer, (c) lateral sewers, J. G. Thorpe, 317 Howes Bldg., town engineer, R. V. Reed, town clerk

POCAHONTAS—The city will soon receive bids for the construction of a sanitary sewer, septic tank and beds in practically all the streets in the city. Estimated cost, $37,000. C. H. Currie, Webster City, engineer.

Maryland

HOMEWOOD (Baltimore, P. O.)—The trustees of Johns Hopkins University have awarded the contract for the construction of a 1-story, 50 x 150-ft. laboratory on Charles St. Ave., to Frainie Bros. & Haigley, 18 Clay St., Baltimore. Estimated cost, $55,000. Noted May 15.

WAGNERS POINT (Baltimore P. O.)—The Mexical Petroleum Co., 1015 Security Bldg., Los Angeles, Cal., plans to build an oil refinery here. Estimated cost, $1,000,000.

Massachusetts

CHICOPEE—The Torrington Manufacturing Co. plans to build an addition to its brass goods plant, here. Estimated cost, $50,000.

Michigan

PONTIAC—C. W. Ham, city clerk, City Hall, will receive bids until June 9 for the construction of sewage treatment works here. C. W. Hubbell, 2348 Penobscot Bldg., Detroit, consulting engineer.

Missouri

DUENWEG—The Log Cabin Mining Co. plans to move the Old Quaker Valley mill from Riverton, Kan., and erect same at Duenweg, and is in the market for a boiler, pump and tables. O. M. Long, manager.

SCOTLAND—The High Grade Zinc Mining Co., Duenweg, Mo., plans to build a new mill here and is in the market for a hoist, rock drills and small compressor. J. W. Baker, manager.

WACO—The Tulsa-Pittsburgh Mining Co., Pittsburgh, Kan., plans to build a mill at No. 2 shaft and is in the market for equipment for same. G. O'Connor, superintendent.

Nebraska

GENEVA—The city received bids for laying sanitary sewers and installing Imhoff tank and sprinkling filters, from S. A. Coneglia, Omaha, $30,225; A. A. Dobson Co., 945 D. St., Lincoln, $30,890; G. Vlasnik, 624 North 32nd St., Lincoln, $31,688.

North Dakota

GRAND FORKS—The State Board of Regents has awarded the contract for installing chemical tables for new chemistry building, at the University of North Dakota, to L. Peterson, 1234 Fullerton Ave., Chicago, Ill.

New Jersey

NEWARK—The Board of Freeholders of Essex County will soon receive bids for enlarging the sewage disposal plant at Overbrook. Estimated cost, $100,000. A. Reimer, county engineer.

TRENTON—The Atlas Tire & Rubber Co. has awarded the contract for the construction of a 1-story, 90 x 360 and 82 x 92-ft. rubber plant on Enterprise Ave., to J. H. Morris Co., 615 Broad St. Bank Bldg. Estimated cost, $250,000.

New York

POUGHKEEPSIE—The State Hospital Commission, Capitol, Albany, will receive bids until June 4 for altering and building additions to the water supply system at the Hudson River State Hospital here. Plans include the installation of additional filters, changing the water mains and building a reservoir. L. F. Pilcher, State Architect.

SYRACUSE—The city is having plans prepared for the construction of a modern rubbish incinerator, to be operated in connection with the new garbage disposal plant, to consist of sorting sheds and furnaces. Estimated cost, $100,000. H. C. Allen, city engineer.

WATERTOWN — The Northern Oil & Fuel Co., 469 Coffeen St., plans extensive additions to its plant; to include the installation of two 50,000-gal. oil and gasoline tanks and completely equipped testing laboratory for handling tests of gasoline, oils and greases. Address G. W. Lane, general manager.

Ohio

SALEM—The city has awarded the contract for the construction of additional filter beds, to the Jones Construction Co., Salem. Estimated cost, $30,800.

Oklahoma

MIAMI—T. L. Green, consulting engineer, would like to receive catalogs and prices on flush tank siphons, intermittent disposal plant siphons, sludge pumps and sewerage and water filtration equipment.

Oregon

SALEM—The Valley Packing Co. has awarded the contract for the construction of a meat packing plant, to F. J. Leonard, Lewis Bldg., Portland. Project includes a 24 x 36-ft. building for rendering tanks, boiler room and fertilizer department. Total estimated cost, $130,000.

Pennsylvania

ALLENTOWN—The city plans to build a sewage disposal plant on a 400-acre farm purchased three years ago, with a capacity sufficient to care for the entire city. It is planned to purify the sewage by a newly discovered process, which makes use of electricity and lime. Work may be done under the supervision of H. T. Bascombe, city engineer. Estimated cost, between $3,000,000 and $4,000,000.

BAKERTON (Elmora P. O.)—The Bakerton Water Co. has awarded the contract for the construction of a water system, to the Ambursen Construction Co., 61 Broadway, New York City, N. Y. Plans include a 30-ft. concrete dam, together with gate house, filters, etc.

BLAIRSVILLE—The Western State Hospital for Insane, Altoona, is having plans prepared by Crooks & Cooley, architects, Jones Law Bldg., Pittsburgh, for the construction of a hospital and group of institutional buildings near here, to include a sewage disposal plant, reservoir, nurses' home and morgue, etc. Total estimated cost, $2,000,000. G. S. Idell, 34 South 16th St., Philadelphia, consulting architect.

BOYERTOWN—The School Board has awarded the contract for the construction of a 2-story high school on 4th St. between Monroe and Madison Sts., to W. J. Elliott, Coatesville. Plans include the installation of an experimental laboratory. Total estimated cost, $115,000.

FRANKLIN—The city has purchased a site on Elk St. and plans to build a sewage disposal plant.

PITTSBURGH—The A. M. Byers Co., 235 Water St., plans to build a 36 x 72-ft. water treating and filtering plant. Estimated cost, $35,000.

South Dakota

EAU CLAIRE (Columbia P. O.)—The Town Council plans an election soon to vote on $40,000 bonds for the construction of a waterworks system, to include filters, pumping station, etc. W. C. McCreight, Union National Bank Bldg., Columbia, clerk.

Tennessee

CHATTANOOGA—The Calvert-Harrison Feature Picture Producing Co. has awarded the contract for the construction of a film factory and studio, to the M. K. Wilson Co., James Bldg. Estimated cost, $50,000.

Texas

CISCO—The city has awarded the contract for the construction of two filtering plants having a daily capacity of 700,000 gal. to the National Water Purifying Co., Dallas. Estimated cost, $25,000.

EAST WACO—The Arrow Refining Co. has purchased a site of 60 acres here and plans to build an oil refinery.

GARLAND—The Gulf Pipe Line Co. has purchased a site of 120 acres here and plans to build an oil refinery.

HOUSTON—The Columbian Refining Co. plans to build a refinery on the ship canal near here. Estimated cost, $500,000.

LAREDO—The Texas Gulf Refining & Pipe Line Co. plans to build an oil refinery on the Texas-Mexico border here. Estimated cost, $250,000.

SHERMAN—The Merchants & Farmers Refining Co. plans to build a refinery here. Estimated cost, $100,000.

Washington

VANCOUVER—The Daily Clay Products Co. is having plans repared for the construction of the first unit of its clay plant. Estimated cost, $50,000. A. H. Haley, Vancouver, architect.

West Virginia

CLARKSBURG — The Lafayette Glass Co. has awarded the contract for rebuilding its plant, to the Memphis Steel Construction Co., Magee Bldg., Pittsburgh, Pa. Estimated cost, $70,000. Noted May 15.

WESTON—The State Board of Control, Charleston, will receive bids until June 14 for the construction of sewage treatment works at the Weston State Hospital, here. Plans include sewage pumping station equipped with two electric motors, two centrifugal pumps and automatic control equipment, also a sewage sedimentation tank, sprinkling filter, sludge bed and chlorinating plant. J. S. Larkin, member.

British Columbia

CASSIDY — The Granby Consolidated Mining & Smelting Co., 718 Granville St., Vancouver, has awarded the contract for the construction of a washing plant here, to the Taylor Engineering Co., 850 Hastings St., W. Vancouver. Estimated cost, $150,000.

Ontario

WELLAND—The Imperial Oil Co., 56 Church St., Toronto, has purchased a site here and plans to build a plant. Estimated cost, $40,000.

Nova Scotia

SYDNEY—The Dominion Tar & Chemical Co. has awarded the contract for the construction of a still house, to the Sydney Foundry & Machine Co., Sydney. Estimated cost, $30,000.

Quebec

GRAND MERE—The Laurentide Co., Ltd., McGibbon St. and 3rd Ave., manufacturer of paper, is receiving bids for the construction of a finishing room. Estimated cost, $30,000. D. Wurtile, c/o owner, engineer.

Coming Meetings and Events

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its Summer meeting at Boston, Mass., June 18-21. A symposium is planned on electric furnaces.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 22nd annual meeting at Atlantic City, N. J., June 24-27. The headquarters will be at the Hotel Traymore.

THE AMERICAN ZINC INSTITUTE will hold its annual meeting at St. Louis, Mo., June 9-10.

THE FRANKLIN INSTITUTE will hold a meeting on May 21 at which the presentation of the Franklin Medal to Major-General James Douglas McLachlan on behalf of his Britannic Majesty's Government for Sir James Dewar will be given, together with the presentation of the Franklin Medal to Major-General George Owen Squier of the United States Army.

THE INTERALLIED CHEMICAL CONFEDERATION will hold its next meeting in London, July 15-18, 1919.

THE NATIONAL FERTILIZER ASSOCIATION will hold its 26th annual convention the week of June 23 at the Hotel Griswold, Eastern Point, New London, Conn.

THE NEW JERSEY CHEMICAL SOCIETY will hold the last meeting before the Summer, Monday evening, June 9, 1919, in Newark, N. J.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its 27th annual meeting at Johns Hopkins University, Baltimore, Md., June 25-28.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its Spring meeting at Erie, Pa., and Buffalo, N. Y., June 11-14 inclusive.

Industrial Notes

THE GELLERT ENGINEERING CO., Philadelphia, Pa., is now erecting electrical precipitators which are being installed at the plant of the American Manganese Manufacturing Co., at Dunbar, Pa., to clean the gases from the blast furnaces. They are expected to be completed by June 1.

THE UNITED STATES & CUBAN ALLIED WORKS ENGINEERING CORP., New York City, announces that Mr. J. A. King has become identified with it as works manager and will be in charge of the corporation's plant, foundry, machine shop and structural works at Havana, the Havana Iron Works, and the marine works, the Havana Dry Dock Co. It is also announced that Mr. Emile J. Bayle has joined the corporation as sales manager.

THE HUFF ELECTROSTATIC SEPARATOR CO., which has been located for the last fourteen years at 60 India Street, Boston, Mass., has recently acquired and fitted up a large plant at Arlington, Mass., a suburb of Boston, to which it has moved its offices, ore-testing and chemical laboratories and works. It maintains a well-equipped laboratory for the purpose of making either preliminary or complete tests showing the results that can be obtained commercially in the separation or concentration of minerals, abrasive materials, and reclaiming valuable content of many waste materials by the Huff Electrostatic process. Mr. H. B. Johnson, an expert in graphite refining, is general manager of the company.

THE ELECTRIC FURNACE CONSTRUCTION CO., Philadelphia, reports the successful starting up of a Greaves-Etchells electric furnace at the plant of the Davidson Tool Manufacturing Corp., Brooklyn. This furnace is used in conjunction with Mr. Davidson's special process for the manufacture of high speed steel castings. Remarkable results have been achieved in the manufacture of high speed steel cutters, drills, boring tools, etc. The company also reports the starting up of a 6-ton furnace at the Navy Department, Mare Island. In England Greaves-Etchells furnaces have been started up for the Tyne Electrical Steel Foundries, Ltd., for the manufacture of steel castings; and a special 6-ton furnace has been installed for W. W. McGregor, of Airdrie, for the manufacture of alundum.

THE MERRILL CO., San Francisco, Cal., is the successor to the Merrill Metallurgical Co., taking over the patents and commercial business of its predecessor. It expects to continue to enlarge its scope as new devices and products become available.

THE BAILEY METER CO. moved its main office and works from Boston to Cleveland, Ohio, on May 1. The Boston office, with Mr. H. D. Fisher, as manager, is retained to handle sales and engineering service work in the New England district. For the present New York and Philadelphia districts will be covered from Boston and all other districts will be covered from Cleveland.

THE OLIVER CONTINUOUS FILTER CO., San Francisco, states that conditions in Mexico are becoming more stable and that metallurgical companies are resuming operations. The American Smelters Securities Co., for example, has recently purchased for the Veta Grande mill at Parral, Chihuahua, six 12-ft. diameter by 16-ft. Oliver filters with complete vacuum equipment. The mill capacity is being increased to 600 tons daily. Sales of similar equipment have been made at the Benguet Consolidated Mines in Benguet, Philippine Islands, and to the Government cyanide plant in the Dutch East Indies.

THE ASSOCIATION OF MEMBERS OF AMERICAN NATIONAL ENGINEERING SOCIETIES IN CUBA was organized in Havana, on Feb. 21, 1919, to foster the interests of the various national engineering societies represented on the island. Membership is restricted to persons who are members of the American Society of Mechanical Engineers, the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Institute of Chemical Engineers, the American Society of Agricultural Engineers, the American Society of Refrigerating Engineers, the Mining and Metallurgical Society of America, the American Institute of Architects, the American Iron and Steel Institute, the American Chemical Society and such other societies as may from time to time be added to the list by the board of directors. It is planned to hold four regular meetings each year for the reading and discussion of papers.

Manufacturers' Catalogs

THE NORTON CO., Worcester, Mass., has issued its 1919 edition of Norton Refractories. This attractive 60-page bulletin is a complete revision of the previous catalog, and contains many additions, including an extensive range of sizes of tubes, muffles and cores, as well as newly developed shapes and a new product known as "electrically sintered magnesia." Prices are given of the various products and also illustrations. A number of tables and charts and a complete bibliography of aiundum and crystolon refractories have been compicted, which makes it useful as a reference book in connection with high temperature electric furnace products.

THE PYROELECTRIC INSTRUMENT Co., Trenton, N. J., has just issued Buli. No. 3, dated Aprii 1919, which gives in four pages illustrations and descriptive matter on the production of carbon free aiioys of high melting point. Circular No. 15 deals with continuousiy deflecting Northrup pyrovolter and pyrometer which contains circuits for checking its indications.

Minerals Separation Wins Doubtful Victory

ON JUNE 2 the Supreme Court handed down its decision in the Butte and Superior infringement suit involving Minerals Separation patent 835,120. This is the same patent which was under consideration in the Hyde case, in which the Supreme Court sustained the validity of the patent and defined its elements to be the use of oil in critical proportions amounting to a fraction of one per cent upon the ore, in combination with greater agitation than that theretofore used, and producing a froth different from any previously produced. But that decision did not, it now seems, define the scope of the claims. The opinion in the Butte and Superior case just handed down defines the scope of the claims as to quantity and character of the oils, and places throughout the most insistent emphasis upon the means described in the patent for carrying out the process of the patent. The process is now stated to be one employing any quantity less than one per cent, on the ore, of an oil or oily substance having preferential affinity for metal over gangue, in which air bubbles are introduced into the pulp by agitation.

As to the operations of the Butte and Superior Company the opinion says:

> The evidence shows, and counsel now admit, that prior to the decision by this court in December, 1916, the respondent used, in its ore concentration operations, various oils in quantities less than one-half of one per cent, on the ore, but that from January 9, 1917, to the time of trial, with the exception of two or three weeks, it used oils of a composition which we shall discuss later on, in quantities in excess of one per cent on the ore. In other respects its methods were substantially those of the patent in suit.

It is interesting to note the last sentence in the above quotation. The opinion adds:

> On this showing, the District Court found the patent infringed by the respondent, when it used oil in quantities greater than, as well as when it used it in quantities less than, one per cent on the ore. . . . The Circuit Court of Appeals held the patent infringed only when the respondent used oil in quantities equal to, or less than, one-half of one per cent on the ore, and it therefore reversed both of the holdings of the District Court, but allowed recovery for the period when less than one-half of one per cent of oil on the ore was used.

It will be seen that there were three periods considered as to the use of oil. The use of less than one-half of one per cent up until the time of the decision in the Hyde case; in excess of one per cent after that time, with slight exception of the periods during which the use of oil was over one-half per cent but less than one per cent.

The Circuit Court of Appeals decided that oil in excess of one-half of one per cent did not infringe; it

> derived its authority to limit the claims to one-half of one per cent on the ore from the construction which it

placed upon the following clause of the opinion of this court in the former case, viz.:

"The patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportions,' 'amounting to a fraction of one per cent on the ore.'"

The reasoning which carried two members of the court to their conclusion was that, as shown by the evidence of the patentees and the argument of their counsel, the amount of oil which is "critical" in the sense of marking the point of transition from the processes of the prior art to the process and discovery of the patent is one-half of one per cent of oil on the ore, and that therefore this court, by using the expression quoted, intended to limit the claims, not to a "fraction of one per cent" but to a "fraction of one-half of one per cent on the ore."

But the Supreme Court reversed the Circuit Court of Appeals, saying:

> The two expressions "critical proportions" and "amounting to a fraction of one per cent on the ore" being used, the former derived from the evidence and the latter from the claims of the patent, obviously, to the extent that they differ—if they differ at all—the language of the claims must rule in determining the rights of the patentees.

Judge BOURQUIN in the District Court had found oil used by the defendant in excess of one per cent an infringement upon the theory that kerosene and fuel oil were of no benefit, when used in a mixture having a quantity of pine oil sufficient in itself to produce the results of the process, and decided that therefore the kerosene and fuel oil should not be figured into the calculation to determine the percentage of oil upon the ore. The opinion asks:

> Does the use of a more efficient, in combination with a less efficient, oil of the patent constitute infringement, where the former is used in an amount within the limits of the claims but the combined amount is in excess of such limit, and when the amount of the more efficient oil used would probably produce better results from the process than are produced with the combination of oils?

Without quoting fully all of that part of the opinion conveying the answer to the above we would state that it is based upon the scope of the claims as well as upon a consideration of the state of the prior art at the time the patent was made, the court saying among other things:

> We held in the former case that the patentees came late into the field of ore concentration investigation and that their discovery rests upon a prior art so fully developed that it was "clear from the record that approach was being made slowly but more and more nearly to the result which was reached by the patentees of the process in suit in March, 1905," and that their final step was not a long one.
>
> Such a patent, in such a field of investigation, must be construed strictly, but candidly and fairly, to give to the patentees the full benefit, but not more, of the disclosure of their discovery which is to become part of the public stock of knowledge upon the expiration of the patent period, and which was the consideration for the grant to them of a patent monopoly.
>
> From this consideration of the terms of the patent as written, it is apparent that it makes no differentiation whatever, either in the claims or in the specification, among the oils having a preferential affinity for metalliferous matter, and that its disclosure, to which the petitioners must be limited, is that when a fraction of one per cent on the ore of any such oil is used in the manner prescribed there will be produced a metal-bearing froth, the result of the process. No notice is given to the public, and it is nowhere "particularly pointed out" in the claims, that some oils or combination of oils, having a preferential affinity for metalliferous matter, are more useful than others in the process, or that some may be used successfully and some not, or that some are "frothing oils," a designation not appearing in the patent, and that some are not. The patentees discovered the described process for producing the result or effect, the metal-bearing froth, but they did not invent that result or froth—their patent is on the process, it is not and cannot be on the result—and the scope of their right is limited to the means they have devised and described as constituting the process.
>
> That the only disclosure as to the kind and amount of oil which the patentees made to the public as necessary to the practicing of their process is that it must be an oil and oily substance, or oily liquid having a "preferential affinity for metalliferous matter," and that it shall be limited in amount "to a fraction of one per cent on the ore."

From the above quotations it is to be seen that the Supreme Court reverses the Circuit Court of Appeals as to its finding with respect to the use of oil between one-half of one per cent and one per cent, but sustains that court as to the non-infringing nature of the defendant's use of oil in excess of one per cent. It reverses the District Court as to Judge BOURQUIN'S opinion regarding the distinction between "frothing oils" and "non-frothing oils" in the most emphatic manner saying:

> To give such a construction to the patent would subordinate the clear description contained in it of what are oils of the process, to an implied and vague description and classification which would leave the whole subject again at large, to become a field for further experimentation, without definition in the patent of what oils or froths would satisfy it.

Referring to the evidence which had led it to the above decision, the Supreme Court says:

> Much of this evidence is especially impressive because the papers from which it is derived were written and the witnesses testified before the question as to petroleum, now made in this case, was raised or discussed.

This apparently imputes a change of front upon the part of Minerals Separation made to meet the exigencies of the case. Such a change of front is also found in Minerals Separation's reducing the violence of agitation as described in the Hyde case in an effort to conform the same patent to the conditions of the pneumatic cell.

A careful reading of this opinion with its numerous phrases emphasizing the necessity of confining the patentees to the "means" of the process as set forth in the patent claims would seem to make it of even greater embarrassment than the Hyde opinion appears to have been when applied to the pneumatic cell. All of the citations to cases made in this opinion as applied to the quantity and character of oil covered by the claims, it seems to us, would apply with equal force to the scope of the claims as to the manner of introducing air bubbles into the mass, which is the question involved in considering the application of patent 835,120 to the pneumatic cell.

The decision is against the Butte and Superior Company in that it brings that company to an accounting for its use of oil in quantity less than one per cent in a process of which the decision says, "In other respects its methods were substantially that of the patent in suit."

Promise of Progress In Rubber Research

THE organization of a Rubber Chemistry Division of the American Chemical Society is to be hailed with favor and all good wishes. The industry has thrived in this country, and it has produced vast wealth, but this has been the result of circumstance rather than because of wisdom and vision within the manufacturing organizations. Some manufacturers have always been progressive, but not all of them, by any means. Most of them employed chemists because they had to, and if

these men could get time off to visit meetings of scientific and technical associations they were usually under instructions to sit still and say nothing, but to bring back whatever they could learn of their competitors' methods and practices.

That is supposed in some quarters to be the very peak of diplomacy and astuteness. When a man of high authority in a manufacturing corporation conceives a thought of that nature his chest swells, and all his little admirers call him a wonder and declare that nobody can beat him! But in the brotherhood of American chemical industries rubber has been scientifically backward, and this is not the fault of the chemists. There has been a lack of men of scientific training on the boards of directors, and. as we have said before and expect to say again, it requires more than business acumen to see the light of science.

It is high time for the rubber industry to take a hitch in its belt and dig into the philosophy of rubber chemistry. The Division provides a start. We shall have now to meet the question whether the authorities will see clearly enough beyond the walls of their works to understand that the way to get ahead is to work together, to permit and encourage chemists to work at research, and to make known their findings. We doubt if there is a single establishment far enough ahead of the game to meet real, intensive research if the manufacturers of some other country should awaken to its value.

In this connection we are always fond of recalling a statement of Dr. JAMES DOUGLAS in one of his "Non-Technical Essays on Technical Subjects," to the effect that those who close the door against the release of information simultaneously raise an equally effective barrier against any knowledge filtering in. The rubber industry of today can learn a profitable lesson from a comparison of present conditions in the iron and steel industry with those of the "good old days" before the spread of technical knowledge.

The Duration Of Prosperity

IF THE steel industry is really the barometer of general trade, it is unfortunate that the barometer cannot be read more closely. For fully a month there have been improved conditions as to steel demand, yet it is uncertain whether the improvement represents merely a delayed spring buying movement or the beginning of a general movement of major proportions.

As to trade in general, it is now rather widely admitted that there is no occasion for men to wait for much lower prices before making purchases or investments. Price deflation has not occurred to any extent and is practically certain not to occur in the present order of things. What occurred after the Civil War is likely, in a general way, to be repeated. There was no price readjustment, to speak of, after the Civil War, but eight years later there came a great panic and then a severe industrial depression of five years' duration.

Many men are now of the opinion that business after the Great War will follow somewhat the same course. This may be a reasonable and correct conclusion, but some men are disposed to apply this conclusion to their conduct in a way that may prove very dangerous. They assume, first, that there will be a gradual deflation in prices and, second, that they will be able to discern the impending depression in time to "get out from under." Now the fact is that the course of iron prices after the Civil War shows conclusively that such a doctrine is very dangerous.

In the first place, there was no clearly marked deflation of prices during the eight years of activity that followed the Civil War, and in the second place men did not foresee the panic and depression that followed and consequently they were quite unable to save themselves.

The prices to be studied, as most indicative of the general trend in the iron industry, are the prices of No. 1 anthracite foundry pig iron at Philadelphia. Then, as now, there was a "pre-war" average of prices, but in view of the exceptionally high prices of 1853 and 1854 a five-year average, 1856 to 1860 inclusive, seems to be the fair one to take. This average was $24.37. There was no Government price control in the Civil War, and the maximum price during the war was $73.75, in August, 1864. In the spring of 1865, at the close of the war, pig iron was $50, or a trifle more than double its pre-war average.

If any one expected materially lower prices to follow the war's ending he was disappointed. There was a slight decline, but in November, 1865, pig iron was $51. Then there was a series of declines and advances, quite suggestive that pig iron was gradually sagging, the low points being successively lower. The lowest decline was to $30, in January, 1871. Then, however, any theory of a gradual and progressive deflation was completely knocked out by facts, for an advance occurred which raised pig iron to $54 in September, 1872, a price higher than obtained when the war closed more than seven years before. One year later, September 19, 1873, occurred the great Jay Cooke panic.

From this sketch of the course of the iron market, presumably as much the barometer of trade then as now, it is readily seen there was no opportunity for one to foresee and prepare for the industrial depression. More than seven years after the war ended and only one year before the panic pig iron was at a higher price than at the close of the war or at any intermediate date.

The only theory that would have saved one from loss would have been to "copper" the market, to conclude that when pig iron had reached such a level as that of September, 1872, it was time to run quickly to cover.

Equally unprofitable would it have been for any one, in 1865 or 1866, to "wait for lower prices," for one might have waited from the war's ending through seven and a half years of great activity, only to find the price higher than ever. The wait for the lowest price of all would have lasted until November, 1878, when pig iron was $16.50. That wait would have lasted more than 13 years, and one whole opportunity would have been passed. It would have paid well to take hold afresh in November, 1878, for the $16.50 pig iron of that month was followed by $41 pig iron fifteen months later.

The experience of what occurred in iron after the Civil War may or may not be suggestive of what is to occur in the next few years, but if the history of those times is to be taken as any guide at all, it should be taken precisely. One should have an exact, not a hazy and more or less inaccurate, conception of what occurred.

Readers' Views and Comments

That Missing Page From the Blue-Back Speller

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to the editorial "That Missing Page From the Blue-Back Speller" in your issue of Dec. 15 last, and to the various comments and discussions on the same, I note that the writers in each case have a particular application in view and do not seem to apply their reasons to general practice. Yet they wish the readers to believe their statements to embody all methods of steel manufacture.

Practice has proved in some plants that the proper pouring temperature of steel is just a few degrees (anywhere from 50 to 100) above the upper freezing point. This means that with a normal size heat of about 50 tons there remains a skull in the ladle after finishing pouring.

But there are certain other practices where a skull is unnecessary, and in fact a pouring which results with skull is frowned upon. The manufacture, in some plants, of bottom-poured ingots for boiler plate is a good example of this latter practice. This steel is the effervescing kind (so named by Henry D. Hibbard), which should always be cast at sufficiently high temperature to permit the escape of considerable amount of gases from the metal during teeming and for several minutes after the molds have been filled. For this practice, then, it is necessary that the metal be so hot as not to permit any resultant skull in the ladle.

With this practice it has been found fitting and proper that the cold additions be made in the ladle instead of in the furnace. When these additions are made in a very fine stream to the metal flowing from the spout the difficulty is eliminated of the steel freezing about the cold solid particles of ferromanganese and the necessity of remelting the combination before the manganese becomes of service. Furthermore, when the ferromanganese is added to the stream of metal from the spout, and when the metal is hot enough to leave no skull in the ladle, there is never any fear of the manganese being unevenly diffused throughout the heat.

By adding ferromanganese to the ladle it is done at a time when the oxidizing influence of the slag and the reducing action of the flame have been removed. The metal is in a passive or neutral state. The stage is, therefore, set for the full and complete reducing action of the manganese. Its whole influence is exerted on the oxides and sulphides in the metal and a clearer, less oxidized metal results. What reduction takes place then is not undone by the slag, such as invariably occurs to a limited extent when additions are made in a basic furnace.

It is felt that the greater loss of manganese, stated by a recent writer, occurring when the ferromanganese is added to the furnace is due not primarily to the activity of the manganese in removing the oxygen, but this loss is due to the oxidizing effect of the slag on the element.

As was stated at the beginning of this article, each discussion on the above topic has been from one specific point of view, but each writer felt he had covered the ground as general practice. I myself have laid before you another specific practice, but I do not wish to generalize it.

My story is not to criticise the practices as brought forward by the several writers, but merely to make plain that the conditions of manufacture are the underlying principles with regard to the addition of cold solid additions in the ladle and that the "Missing Page" must be supplied according to the requirements of the individual practice.

A. L. MEYER.

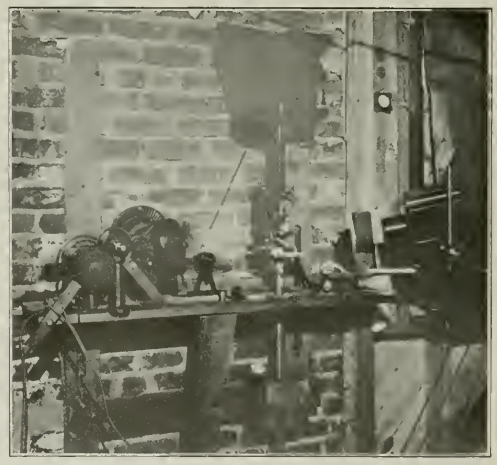
Photography in Research

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have noted with interest the article in your recent issue descriptive of an application of microscope and motion picture camera to the structure of steel under stress. It may be of interest to your readers to know that a similar combination of apparatus has been used by the writer for some five years past in the study of the setting processes of concrete as affected by temperature and other variables; the manner in which cement attaches itself to sand and to stone; the processes incident to attack by fresh and sea water on concrete; disruption by frost; stressing and disruption of concrete



MOTOR-DRIVEN APPARATUS FOR TAKING PHOTOS AT REGULAR INTERVALS

under strain; shrinkage and crazing through evaporations; the effect of temperature; humidity, etc.; on rusting of steel (rust is disclosed as a phenomenon of rare beauty); the oxidizing and deterioration of paints and protective coating; and various other matters of professional interest to me. As a result of these studies, new processes which give promise of wide usefulness are nearing commercial success. A lecture with such films as relating to concrete has been delivered at various places this year and seems materially to have assisted the understanding of auditors as regards these usually obscure and unknown processes.

For the taking of accurate studies, in all of which time enters as a most important factor, the hand-actuated camera shown in your illustration was early discarded. In its place, the motor-driven apparatus shown in the

illustration herewith was constructed from stock gears and a $10 camera of early vintage. By its means, pictures may be taken at any desired intervals from $\frac{1}{10}$ second to 3 hours between exposures, unvaryingly, day and night over protracted periods. Furthermore, as this has been a diversion as well as a serious study, the use of automatic means has permitted attendance on other duties without interruption.

I would further say that the use of oblique illumination of opaque objects and of dark ground illuminator for transparent or semi-transparent subjects extends the range of research far beyond those included within the possibilities of vertical illuminators.

The general scheme is an admirable tool. Let us hope for its early and general extension of use.

New York City. NATHAN C. JOHNSON.

Modification of the Cyanide Method for the Estimation of Nickel in Steels

To the Editor of Chemical & Metallurgical Engineering

SIR:—The method, as outlined below, is the common cyanide method, using ammonium citrate to hold the iron in ammoniacal solution—with several differences. The differences are the method of introduction of the silver nitrate into the solution to be titrated and the elimination of hydrochloric acid in dissolving the steel.

It is a fact not generally known among iron and steel chemists that silver nitrate is soluble in concentrated potassium iodide solution, due to the formation of a double salt. (See Prescott and Johnson, Qualitative Analysis.) This double salt breaks down to silver iodide and potassium nitrate on dilution. This modification takes advantage of these facts by the use of an indicator solution containing silver nitrate and potassium iodide, the only precautions being necessarily the use of this indicator in definite quantity in each determination and the determination of a blank, to be subtracted from each titration.

The method as at present in use in this plant is:

Weigh a 1-g. sample into a 250-cc. beaker, dissolve in 30 cc. nitric acid (1.20 sp.gr.) and evaporate to 8 or 10 cc. Remove from the hot plate and add 50 cc. sulphuric and citric acid solution. Cool, make faintly but distinctly alkaline to litmus paper with ammonia and dilute to 150 to 175 cc. Cool to room temperature, and add exactly 2 cc. special indicator, from a pipette or a burette, and titrate with standard potassium cyanide solution until the solution just clears.

SPECIAL INDICATOR

0.2925 g. Silver nitrate
30.0 g. Potassium iodide
Distilled water to make the volume 100 cc

SULPHURIC AND CITRIC ACID SOLUTION

200 g. Citric acid
600 cc. Distilled water
400 cc. Sulphuric acid (1 to 3)

STANDARD POTASSIUM CYANIDE SOLUTION

4.5 g. Potassium cyanide (or equivalent in sodium cyanide)
1000.0 cc. Distilled water
5.0 g. Potassium hydroxide may be added, but is not necessary.

Standardize by putting 1 g. of a standard steel through the above manipulations. A blank, representing the amount of standard solution necessary to clear 2 cc. of the special indicator, must be deducted from all titrations. This blank is best determined by running a nickel-free steel through the method, but diluting 2 cc. of the special indicator to 150 cc. with water, and titrating, will be sufficiently accurate for routine work.

Western Chemical and Metallurgical Field

Pig Iron, Ferros and Sponge Iron at Heroult

IN VIEW of the fact that the Noble Electric Steel Co. has been a pioneering experimenter in electric pig iron on the Pacific Coast, its friends will be glad to know that its most recent investigations on low-temperature reductions have been very encouraging, and entirely successful in a small-scale unit.

Electric smelting was commenced by this company in 1907 under the direction of H. H. Noble, when the late Dr. Paul L. T. Heroult constructed a 2000-hp. rectangular furnace with arched roof, having three electrodes alternating with four vertical charge chutes. Escaping gases were led upward through these chutes to preheat and reduce the ore, but in operation the heated ore hung in the chutes, and a very hot top melted the roof. Some iron was made in this early furnace, but a single-phase furnace of 160 kw. was built in 1908 under direction of Dorsey A. Lyon, and this was followed the next year by a tall shaft furnace (quite similar to the independently developed Swedish type), whose operation continued intermittently two years. With the latter it was found extremely difficult to control the carbon in the resulting pig iron (soft, high-silicon foundry iron was desired by the available market), since excess carbon could not be burned off, and deficiencies of carbon and segregation of constituents often occurred during settlement of the charge. Long, narrow, closed-top furnaces of 2000 and 3000 kw. capacity similar to Dr. Heroult's were therefore built in 1912, and continuously operated without preheating the ore in the charging chutes. John Crawford described the results from these furnaces in METALLURGICAL & CHEMICAL ENGINEERING, July, 1913, Vol. XI, p. 383. Iron containing 2.9 per cent Si, 0.1 per cent combined carbon and 3.4 per cent graphitic carbon was made with a minimum power consumption of 2200 kw.-hr. per ton (0.40 hp.-yr. at 85 per cent load factor).

Other circumstances than undeveloped technology militated against the success of the Noble Steel Co. Its plant is situated in the northern part of California in mountainous country removed by long rail haul from the source of the company's miscellaneous supplies and its market. Ore and flux are near by, but the timber was rapidly exhausted. As a last straw, the men most interested in the steel company lost control of the Northern California Power Co. in 1914 and their rates for energy immediately doubled, forcing a closure of the plant as far as the commercial production of pig iron was concerned. A very good quality of pig iron was made in one of their open pit furnaces in a campaign during the months of January and February of the present year. This furnace had an open top, and had been used to produce various ferro-alloys. Over 95 per cent of the iron in the ore charged was recovered as metal with a power input of 2400 kw.-hr. per short ton of pig iron.

As an offset to the many disappointments as iron producers, the following brief record of successful alloy practice should be made:

In 1907, Petinot, using the original Heroult furnace, made ferrosilicon, and plans were made for the production of ferrochromium. Owing to the lack of a ready market for the alloys, this work was set aside, and all effort concentrated on the iron problem during the following seven years.

In the fall of 1914, Crawford made ferromanganese in the furnaces described by him in METALLURGICAL & CHEMICAL ENGINEERING, Vol. XI, p. 383, but he was unable to co-ordinate the electrical and metallurgical conditions of the burden in a closed-top furnace, and still produce a standard alloy with the low-grade ore supplied him.

In 1915, Scott, followed by Gosrow, using the smaller Crawford furnace with the top removed, established a good furnace practice on ferromanganese with ore of standard specification. They were forced to discontinue operations, however, when the grade of ore fell off.

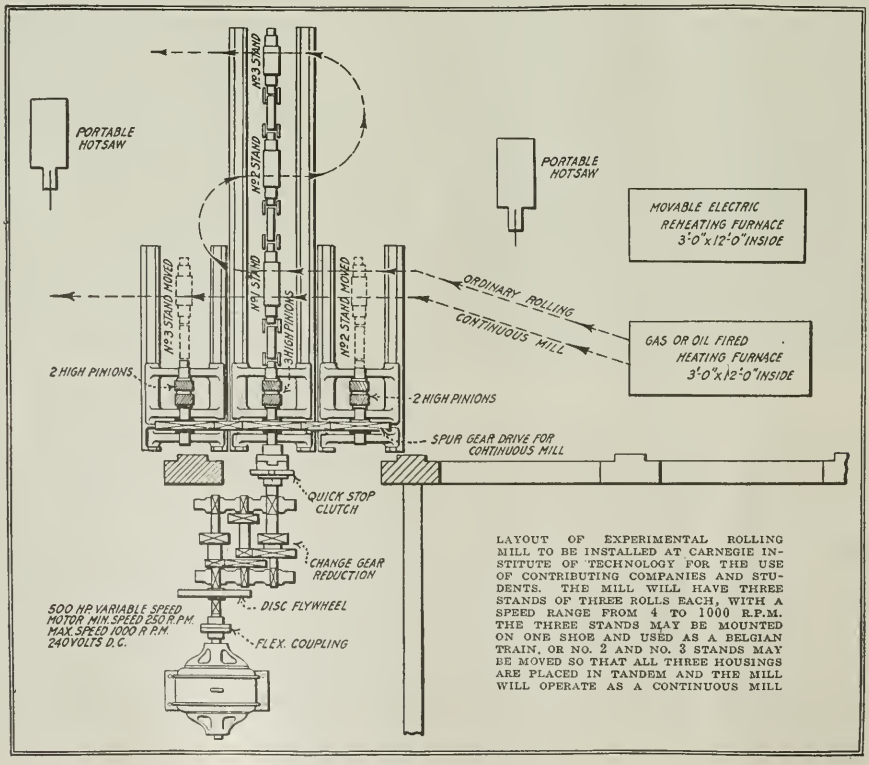
From April, 1916, until March, 1919, the plant ran continuously on ferro-alloys, with operations varying in volume from one to four furnaces, as raw materials could be obtained. During this period, ferromanganese was the main product, and ferrosilicon, ferrochromium, silicomanganese and pig iron were produced in small amounts when the demand was strong. During these latter operations, the problem of low-temperature reduction of iron ores was approached—not an entirely new venture to the Noble company, since about seven years previously, in 1911, it installed a series of small portable electric furnaces for making sponge iron, and a large tilting type (2000-kw.) furnace for melting. A mechanical device, similar to the open-hearth charging machine, periodically emptied the contents of a small furnace into the melter. Mechanical difficulties and lack of metallurgical control soon caused the abandonment of this experiment, however.

Recently these attempts were revived in view of the large increase in power cost. It is essential to reduce its consumption if electrical smelting is to succeed, and the most promising method seemed to be to separate the reduction stage from the melting stage.

According to Dr. Stansfield's recent report on the commercial feasibility of the electric smelting of iron ores in British Columbia, reduction can be done at 700 to 800 deg. C., and absorbs about twice as much heat as the actual melting, which involves a high temperature—1400 to 1600 deg. C. In a combination process, electricity might be used for the development of the high melting temperatures only, for which it is most efficient. In this manner, simple melting can be done with 600 to 700 kw.-hr. per ton, while reduction followed by melting requires nearly four times as much power.

Dr. Trood and Mr. W. A. Darrah carried out a series of experiments following this idea at Heroult last year, using the Noble Steel Co.'s pure magnetite. The work was done in a small furnace, electrically heated, making a few pounds of reduced iron per hour. Reduction of magnetite by powdered charcoal commences in the neighborhood of 700 deg. C., but commercially it would appear to be advisable to speed up the reaction by operating nearer 800 deg. C., at which it requires about three hours effectually to reduce ore particles the size of coarse sand. The resulting sponge can then be melted electrically to either pig iron or steel, or, after briquetting, melted in a gas-fired open-hearth furnace.

From these rather small-scale experiments, Mr. Darrah



estimates the cost of sponge iron at $19 per ton. His items for crushing, handling and labor are possibly somewhat optimistic, while charcoal costs, though apparently very high, are still considerably less than the present market in those regions.

His items are as follows:

Item	Cost	Quantity Required	Total Cost per Ton of Iron
Power for drying and reduction	4c. per kw.-hr.	1,200 kw.-hr.	$6 00
Charcoal	$25 per ton	570 lb.	7 10
Ore	$3 per ton	2,760 lb.	4 15
Crushing materials	50c per ton		.69
Handling materials	50c per ton		.69
Labor and supervision			.50
Interest and depreciation on $20,000 investment			10
Total			$19 23

In commenting on these figures, Dr. Stansfield notes that the charges appear very small, but are perhaps not underestimated, owing to the continuous nature of the mechanical operations and the small amount of labor required.

Accepting Mr. Darrah's figures, Dr. Stansfield compares the cost of a ton of foundry iron by the direct process to that of white iron in a Swedish furnace (British Columbian conditions) as follows:

	FOUNDRY PIG FROM SPONGE IRON			WHITE IRON IN ELECTRO-METALS FURNACE		
	Plant Capacity 36,500 Tons Yr.	Rate	Amount	Plant Capacity 27,000 Tons Yr.	Rate	Amount
Ore	2.2 tons	$4 00	$8 80	2 tons	$4 00	$8 00
Crushing	2.2 tons	.50	1 10			
Handling	2.2 tons	.50	1 10			
Producer gas for reduction	Coal at $4		2 50			
Charcoal for reduction	½ ton	6.00	2.00			
Labor and supervision			.85			
Interest and depreciation			.25			
Total for sponge iron by gas			$16 60			
Electric power	750 kw.-hr.	0.5c.	3 75	2500 kw.-hr.	0.5c	12 50
Charcoal	0 1 ton	6 00	60	0 4 ton	8 00	3.20
Electrodes	7 lb.	8.5c.	60	15 lb.	.08	1.20
Fluxes and supplies			55			
Repairs and maintenance						1.00
Labor and supervision			3 00			6.50
Interest and depreciation			1 50		16%	2.60
Royalty						0 50
Total cost			$26 60			$35 50

Steel Research Laboratory

It was announced in April that Prof. W. Trinks of the Carnegie Institute of Technology had secured the interested co-operation of a number of steel companies and equipment manufacturers in the Pittsburgh district in organizing a Bureau of Rolling-Mill Research. This bureau will be under the direction of Mr. W. B. Skinkle and supported by funds advanced by the co-operating firms. The accompanying sketch of the proposed installation is self-explanatory, and immediately suggests the wide range of data which can be secured.

Adequate indicating instruments will be installed, so that not only the metallurgical results but the main stresses in the stands, rolls and pinions may be studied during variation in the speed of rolling, the degree of reduction, the diameter of rolls, the shape of the pass, or the analysis and temperature of the steel.

This bureau, in addition to its program of studies such as noted above, will distribute the derived information to the contributing firms for commercial exploitation, and will provide facilities for special researches by their engineering staffs, as well as constituting a laboratory of instruction for regular and special students at Carnegie Tech.

Company Reports

Calumet & Arizona Mining Co.—The smelter at Douglas operated continuously, but on a reduced ore tonnage, amounting only to 68 per cent of capacity. Ore receipts are continually decreasing in oxidized mineral, and in case proper and economical crushing arrangement can be worked out, all the material will be roasted and sent to reverberatories, practically disusing the blast-furnace department. During 1918 376 blast-furnace-days smelted 313,695 tons of dry charge, compared to 602,272 dry tons treated in 1065 reverberatory-furnace-days. Header flues for the latter furnaces were rebuilt of refractory brick to larger dimension, directly increasing the smelting capacity 40 per cent. Some blast-furnace jackets in continuous service since June, 1913, were replaced owing to corrosion of the water surfaces, the inner face exposed to the heat showing very little wear.

New Cornelia Copper Co.—This company has completed its first full calendar year as a producer of copper. During this year all bonds were converted into stock, the greater part of the indebtedness liquidated, and a first dividend of 25c. per share paid. Production was as follows:

Electrolytic cathodes	21,764,642
Cement copper	19,990,666
Copper in ore shipped	4,694,831
Total	46,950,139

Operating and general expenses, freight, refining, selling, taxes, interest and depreciation amount to $7,490,000, a total of nearly 16c. per pound. Apparently about 13,000,000 lb. of this copper was on hand at the end of the year, or more than a quarter's output, so operations were curtailed to 60 per cent of capacity on Feb. 1, 1919. In order to increase the plant to a monthly production in excess of the 3,000,000 originally designed, a fourth motor-generator set for electrolytic power is being installed a fifth unit of 3 Symons disc crushers added to the fine crushing plant, the SO_2 reduction capacity doubled by the addition of two large towers. Nearly 1 lb. of copper per ton was saved by giving the leached ore five instead of four wash-waters. It is anticipated that the mine will be able to produce 5000 tons daily of sulphide ore (1.6 per cent copper) within three years. Consequently $160,000 was appropriated for a 500-ton test mill to determine largely the proper method of grinding the ore and the correct flotation practice. This mill is now nearing completion. "The operation of the New Cornelia Co-operative Mercantile Co. was very successful. A discount of 15 per cent on purchases for the year was paid to 773 employees."

American Smelting and Refining Co.—This company was able to accumulate earnings applicable to dividends of $7,700,000 despite the pessimistic statement of President Daniel Guggenheim in the preceding report that "By these two governmental actions, first, by reducing the value of our product, and, second, by constantly increasing our cost, this great corporation . . . is having its ability to pay a fair return to its stockholders seriously jeopardized." The report for 1918 further recites that during the last three years nearly $20,000,000 has been expended for new property and construction in addition to renewal of absolescent construction, the cost of metals carried has increased over $17,000,000, and the demand on excess cash resources further increased to a total of over $42,000,000 by Liberty Bond holdings, all of which have been met without necessity

of borrowing. The board of directors may thus be pardoned their justifiable pride in their conservative management. "A comparison of the condition of the company in 1902 and of the two companies [A. S. & R. Co. and American Smelters Securities Co.] will be instructive, the figures given in the following table being approximate only:

	1902	1918	Increase, Per Cent
Quick assets	$18,000,000	$50,000,000	175
Profit and loss account	2,900,000	27,000,000	816
Annual turnover	82,000,000	390,000,000	372

Further quoting from the report, "The most discouraging condition during the war years has been the great increase in our costs of smelting and refining, while the company was without power to correspondingly increase the charges to the mines for doing this work. But these costs are already considerably decreased, and although pre-war costs may never be realized again, the board does expect that pre-war profits per ton of ore smelted will be obtained as soon as normal business is resumed."

Inspiration Consol dated Copper Co.—Successful operations continued despite a shortage of labor and a corresponding decrease in its efficiency; comparative mill statistics are as follows:

	1916	1917	1918
Tons milled	5,316,350	3,891,075	5,110,101
Average rate per section	897.8	936.7	956
Mill feed, per cent copper	1.548	1.388	1.361
Mill tailings	0.397	0.355	0.380
Flotation concentrates, per cent copper	37.50	35.57	35.26
Sulphide recovery, per cent	90.95	89.73	88.51
Gallons water per ton ore	226	348	310
Ball consumption, lb.	1.76	1.82	1.82
Flotation oils per ton, lb.	1.287	1.32	1.35

Nipissing Mines Co., Ltd.—High-grade ores have been treated for seven years by an amalgamation process using large quantities of mercury. The war-time increase in price from about $35 to $130 made this process so expensive that it was decided to rely upon cyaniding alone, after giving the ore a preliminary treatment with bleaching powder in the tube mill. The necessary apparatus for this change was installed in the low-grade mill, and the high-grade mill shut down about the middle of the year, but will probably be revived as soon as the price of supplies justifies the step. In the low-grade mill at present the ore is crushed by stamps in cyanide solution and sent to the roughing tables without classification. The tailing from the tables is classified, the sand being recrushed in tube mills, and the undersize sent to the fine sand tables. The tube mill discharge is returned to the classifier, while the tailing from the fine sand tables is cyanided. By this method 48 per cent of the silver is recovered in the form of a concentrate, 40 per cent as precipitate from the cyanide plant, and 12 per cent is lost. The concentrate is retreated in the high-grade mill with high-grade ore, and the precipitate from both treatments is sent to the refinery, where it is converted into bullion. This process can give a better extraction at a lower cost than can be obtained by cyanide alone on the present quality of ore, due consideration being given for the value of the cobalt in the concentrate.

United States Smelting, Refining & Mining Co.—Operations in Mexico appeared to have run on a normal basis, the two mills at Real del Monte and Pachuca having treated 690,000 tons of ore. This tonnage will be increased to about 80,000 tons per month on completion of additions now under construction. In Utah, on account of the abnormally large ore supply available at the Midvale plant, it was found advisable to enlarge the installation by one blast-furnace. For a short time all seven of these furnaces were in operation, but for the remainder of the year one or two of them were down. The zinc operations were not so successful, since a failure in the gas supply caused the closing down of the Checotah smelter early in the summer. The Mammoth smelter at Kennett, Cal., operated throughout the year at capacity, in spite of difficult conditions in labor and material supply. Experiments have continued on the new electrolytic zinc process, but production cannot be expected until more favorable market conditions occur. Construction of the surface plant at Sunnyside was completed, and the mill gave promise of fulfilling all expectations. This plant was seriously damaged by fire within the past few weeks, however.

Consolidated Arizona Smelting Co.—A program of reconstruction started four years ago was practically brought to completion during 1918 with results in operation fully justifying preliminary estimates. For instance, the new roadster plant and its accessories, costing a total of about $300,000, has saved approximately $100,000 in improved metallic extraction during the first year, in addition to an operating economy of about $150,000. There is apparently little justification in maintaining antiquated departments when a modern design nearly pays for itself in 12 months. Improvements in reverberatory smelting have increased the capacity to a point where blast-furnace smelting had been discontinued, and notwithstanding large increases in cost of labor and supplies (especially fuel oil) and a corresponding increase in mining and milling costs, copper was produced in 1918 for 14.683c. per lb. as against 14.98c. in 1917.

Phelps-Dodge Corporation—The following is a tabulation of the milling data contained in the last annual report:

	Moctezuma	Burro Mountain	Morenci
Dry ore milled, tons	762,029	585,083	449,990
Copper content	3.392%	1.928%	1.910%
Tailings	0.627%	0.630%	0.519%
Extraction	85.6%	70.2%	76.2%
Gallons fresh water per ton	666	737	.....
Kw.-hr. per ton	12.54	10.16	.....

At Burro Mountain the proportion of sulphide copper in the ore decreased to 1.65 per cent, which caused a slight drop in sulphide in tailings to 0.44 per cent. Extensive experimental work has developed the fact that fine grinding in closed circuit, more flotation units and additional tables below flotation will increase this extraction, and plans are being drawn up for a corresponding revision in the flow sheet.

Stripping operations on Sacramento Hill (Bisbee District) have been about 30 per cent completed, and at the present rate a daily production of 4000 tons of ore can be maintained within 18 months. The new concentrator for this service was designed under direction of H. Kenyon Burch, but its construction has been postponed until market conditions are more favorable.

Fall Meeting of the American Electrochemical Society

The next meeting of the American Electrochemical Society will be held in Chicago, Sept. 23 to 25 inclusive, during the week of the National Exposition of Chemical Industries. This Middle West meeting in conjunction with the Exposition affords a combination of circumstances which will undoubtedly bring a large attendance. Work on the program is actively under way by the officers of the Society and a symposium on catalysis is being arranged as a special feature.

Electric Power Production

THE following table is based on a report issued by the Geological Survey for the month of February, 1919. Returns were received from 3150 electric power plants engaged in public service, including central stations, electric railways and certain other plants the output of which contributes to the public supply. As these returns represent 85 per cent of the total capacity, estimates of output were made from available information for those plants which did not make returns or which were unable to furnish the data requested.

ELECTRIC POWER PRODUCTION MONTH OF FEBRUARY, 1919

State	Capacity, Kw.	Thousands of Kw.-Hr. Produced By Water-Power	By Fuels
Alabama	165,688	39,372	12,939
Arizona	91,363	3,967	16,395

Wisconsin	351,215	28,284	32,709
Wyoning	21,031	251	3,542
Total	12,665,309	1,220,972	1,879,182
Combined total			3,100,124

The power produced by fuels (1,879,182,000 kw.-hr.) resulted from the combustion of 3,007,815 short tons of coal, 662,770 bbl. of petroleum and derivatives and 1,693,401,000 cu.ft. of natural gas.

Dedication of New Bureau of Mines Laboratories

The Bureau of Mines announces that during the week of Sept. 29 the new million dollar laboratories and workshops in Pittsburgh, Pa., will be formally dedicated. High officials of the Government, together with the Governors of the principal mining States and the leaders in the mining industries and miners' organizations, will be present to take part in the dedicatory ceremonies. A feature of the dedication will be a great national Safety-First meet, teams of miners from all over the country competing for cups and medals. There will be contests in rescue work and in first aid to the injured, and as there is immense rivalry between the teams of the different mining companies, it is expected that these contests will take at least two days for decision. On Sept. 30 the elimination contests will begin at Forbes Field in Pittsburgh and will continue until only the winning teams are left for the final championship contests, which will take place on Oct. 1 immediately after the elimination trials are completed.

The different laboratories of the bureau have been completely equipped for the investigation of the various problems relating not only to greater safety, but also to greater efficiency in the mining and metallurgical industries. Visitors will be invited to the electrical and mechanical workshops and laboratories of the bureau and also to the petroleum, gas and coal laboratories, the testing gallery of the mine safety section, and the industrial gas-mask division. Another point of interest will be the experimental mine of the bureau at Bruceton, Pa., twelve miles from Pittsburgh, where an actual explosion of coal dust in the mine will be staged for the benefit of those attending. At the experiment station there is also to be shown a complete exhibit representing the mining and metallurgical industries of the country.

April Imports and Exports

The Bureau of Foreign and Domestic Commerce of the Department of Commerce reports for April, 1919:

DOMESTIC EXPORTS OF CAUSTIC SODA AND SODA ASH FROM U. S. TO ALL COUNTRIES

Countries	Caustic Soda — Lb.	Caustic Soda — Value	Soda Ash — Lb.	Soda Ash — Value

Alloy Steels for Helmets and Armor

Notes on Steels of Various Compositions and of High Penetrative Resistance Used for Protective Purposes by the American Army—Details of Electric-Furnace and Rolling-Mill Practice Are Presented

By JOHN A. COYLE

EARLY in America's participation in the war, a prominent Pittsburgh District steel company was asked to produce sheet metals for helmets, the principal specification being that a sheet 0.035 in. thick (20 gage) should withstand a .44 Colt bullet with a muzzle velocity of 840 ft. per sec. at a distance of 10 ft., point blank impact. This was successfully met—ballistic tests of this sort denting the finished helmet over a roughly circular spot of 3½ in. diameter to a depth of perhaps one-half inch.

To produce such metal, experiments were first performed upon manganese-vanadium steel produced by the steel company in its own furnaces, and with the following chemical composition:

C	0.40 to 0.50
Mn	0.80 to 1.00
V	0.20

(Silicon, sulphur and phosphorus normal.) Indifferent results attended these efforts, and no helmets were produced of this analysis; seemingly some other alloying element was needed, or else the relative proportion of those used was not exactly right.

Hadfield's Manganese Steel

Slabs of Hadfield's manganese steel (C, 1 per cent; Mn, 12 to 13 per cent) were then procured from an outside manufacturer and sufficient sheets produced to make about 25,000 helmets. Production was slow and uncertain for a variety of causes, however, and this particular material was abandoned as non-commercial. In the first place the slabs were made from converter steel, and differed widely in quality—a very considerable quantity was returned to the maker as worthless. As received at the rolling mills, the slabs had been quenched from 1800 deg. F., after which this manganese steel could be readily rolled in ordinary mills with the heat treatment usually given mild steel. However, as the slab was reduced there was a marked tendency for the edges and corners to curl up, so that when it was necessary to pair two of them together for the final passes, the sheets could not be readily matched. This fact alone was sufficient to start a search for more workable material. A peculiar characteristic of quenched Hadfield's steel is that it shears easily but cannot be cut with ordinary lathe tools or drills. While it can be pressed cold, a limit to such working is soon reached, since it hardens progressively after continued cold work.

Armor of Nickel-Manganese Steel

A nickel-manganese steel was then produced in quantity in a 6-ton Heroult furnace, a unit of the steel company's equipment, from which 106,000 helmets were successfully made without a single rejection. The analysis follows:

C	0.37 to 0.47 per cent
Mn	0.95 to 1.05 " "
Ni	2.00 " "
V	0.15 to 0.25 " "
Si	0.15 to 0.25 " "
P	0.02 max. " "
S	0.02 max. " "

This material worked very readily—the product after annealing being a dead-soft sheet which could be bent flat upon itself in any direction without sign of fracture. No difficulty was experienced in the sheet mills when following the usual mild-steel practice; the final workable annealing was done in pots at 1700 deg. F. for 10 hours, cooling in the furnace requiring 14 hours to reach 60 deg. F. In such condition the sheets could be readily straightened and trimmed after ordinary methods.

An Indiana enameling and stamping company shaped the helmets to pattern provided by the Government. Originally it was intended to do this in four operations, each separated by an annealing in a continuous furnace some 26 ft. long, heated by side gas-burners to a degree just below recalescence. Passage through this furnace required 3 min., and such treatment apparently relieved any cold-working strains entirely. About 2000 helmets were made in this manner, when experiments demonstrated that the entire shaping could be done in one draw without endangering the impact resistance of the finished helmet. The balance were made in that manner, therefore, the annealing for strain described above being followed by oil quenching from 1500 deg. F., and drawing in oil at 450 deg. F., which practice produced a satisfactory helmet. Another contractor ruined a few of these helmets by a little heat during a sanding and baking operation, but this practice was soon remedied.

With the problem of commercial production of helmets solved, attention was next turned to an armor required by the army, which, when 0.175 in. thick, would resist penetration by a copper covered bullet from a Springfield rifle (muzzle velocity 2140 ft. per sec., range 50 yd.). Some of this specification was produced from metal with the analysis first given—that is, 0.45 carbon, 0.90 manganese and 0.20 vanadium—but apparently a little variation in the chemical composition had a disproportionate effect on the ballistic results. After trials it seemed that higher manganese acted somewhat as a stabilizer, and the following analysis was adopted:

C	0.37 to 0.47
Mn	0.95 to 1.05
Ni	1.85 to 2.15
V	0.15 (as a scavenger)
Si	0.15 to 0.25
P	0.02 max.
S	0.02 max.

Such material appeared satisfactory from many angles

and its quantity production was under way upon the termination of hostilities; in all 9000 tons were made by the company in question.

Melting in Electric Furnaces

As noted, the bulk of this special sheet was made in a 6-ton Heroult electric furnace, which is an ideal producing unit for making ferrous alloys of highest purity. Owing to the pressing demand, an available crucible furnace was also utilized, 24 pots of melted steel and one-half pot of liquid ferromanganese were mixed in a pre-heated ladle before casting into ingots. This was merely an expedient, however, since nearly all of this special metal was made in an electric furnace, a brief description of whose operation may therefore be of interest.

Assuming that the furnace has been fettled after a previous heat, solid charge is placed through the side doors with all possible speed, some 45 min. being required at the best. The load consists of approximately:

1700 lb. wash metal (low-phosporus pig with 3½ per cent C)
6000 lb. low-phosphorus steel scrap
5200 lb. commercial mill-scrap
A varying quantity of ferromanganese
A varying quantity of nickel, 98 per cent pure
300 lb. lime
45 lb. fluorspar

A 110-volt current is then switched on, the doors closed and melting proceeds. Surges of current in cold charged metals are more than considerable, giving up to 10,000 amperes momentarily, but the bath settles to quietness in 30 min. at most. Various systems of electrode regulation have been tried, each of which produces various results, more or less acceptable. From the time of cessation of surging current due to cold charges, melting requires about 2 hr. 45 min., during which time certain reactions are taking place in the metal, so that when the bath is completely fluid, the charge which originally totaled 1.04 carbon, 0.17 silicon, 0.045 phosphorus and 0.035 sulphur, has been reduced to 0.34 carbon, 0.035 phosphorus, 0.04 silicon and 0.030 sulphur.

Dephosphorization

Dephosphorization then proceeds to completion in a bath of moderate temperature in about 45 min. During this period the current consumption is well balanced on the three electrical phases, and while the current input is at maximum of about 450 kw. per phase, the just-melted metal, of course, takes up the heat gradually, and it is during this increase in temperature that the phosphorus is eliminated. When the temperature rises till the optical color appears, which is a white heat above pale yellow, dephosphorization ceases.

Temperature in the furnace is controlled by the eye of an experienced melter combined with his knowledge of the influence of electrical input—a method leaving much to the "personal equation" and capable of large improvement. Unfortunately, however, pyrometric science has not yet solved the problems presented by the electric furnace. Its heat is derived from radiation from an intensely hot arc, and consequently the interior is far from the black body condition demanded by optical pyrometers, while the presence of oxides or carbon films on the slags changes the emissivity factor of the bath continually. The best indication of a furnace's performance during the dephosphorization stage yet found and practiced is a continuance of the ancient slag test—a button of slag after quenching exhibits a peculiar black color and rather indescribable luster, which when recognized is a sign of good work. This physical indication is immediately confirmed by rapid chemical analysis, which is constantly the furnace operator's guardian angel.

When dephosphorization is complete, the metal will have the following approximate composition:

C	0.300	per cent
Si	0.050	" "
P	0.015	" "
S	0.025	" "

The furnace is then tilted slightly and the slag carefully and completely skimmed off through the tapping spout with the aid of wood and metal rakes. Here a word about furnace lines may be apropos. It is well

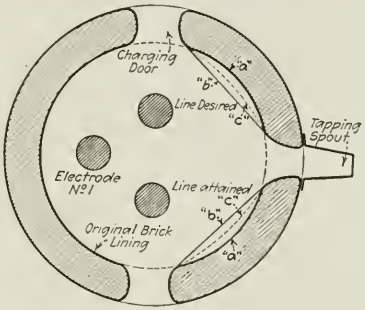

FIG. 1. SKETCH OF HEARTH OF ELECTRIC FURNACE (SECTION THROUGH SIDE WALLS)

known that if any phosphorus-bearing slag or other material remains in the furnace, the phosphorus will reenter the metal at the high temperature reached during desulphurizing, yet little attention in many so-called furnace "designs" is given to the practical problem of making all parts of the bath and banks easily accessible to the skimmer. Thus, an ordinary Heroult furnace may have side walls built somewhat similar to those shown at *a* in the accompanying sketch (Fig. 1). It is readily seen that the little bay formed between charging door and spout is almost inaccessible to the skimmer, and little shelflike crusts of slag are liable to remain in this relatively cool part of the furnace, submerged slightly in the metal, with disastrous results to the final analysis. Proper attention to banking up the side walls with granular fettling may bring them out to the line shown at *b*, but normally the best that can be continually maintained in commercial practice would be some intermediate and rather unsatisfactory mean position such as *c*.

Desulphurization

After the skimming operation, which requires about 15 min., the doors are opened long enough to charge in a few shovelfuls of ingredients for the carbide slag. This is composed primarily of lime, fluorspar and crushed coke, with a little washed silica sand (free from alumina) added to intensify the deoxidation necessary to the proper desulphurizing action of carbide. Desulphurization requires between 60 and 90 min. at a very high temperature. After charging and superheating this slag, the current is reduced to about 80 per cent of maximum input, so that the arc may disturb the

bath as little as possible, since the desulphurizing slags act best after rabbling in, under quiescent mass conditions.

As before, the best quick indication of the desulphurization progress is had by eye examination of slag tests—a proper slag should be pure white above gray, and the quenched piece should give a clear odor of acetylene, indicating the presence of carbide. Such slags need constant attention, building them up as necessary by further additions of their ingredients. Little if any of the pulverized coke enters the metal bath as such to influence its carbon content, since it floats on top the slag layer and continually forms the calcium carbide required for desulphurization.

During this stage the metal is sampled at short intervals and a series of chemical analyses indicate the course of the carbon and manganese elimination. Preliminary nickel assays are also made, although little trouble is experienced with this element—practically 100 per cent recovery of the metal charged at any stage is had. Indeed, it may be remarked in passing that alloying elements (other than deoxidizers and scavengers) may be recovered almost quantitatively by proper attention to melting practice and by protecting with high-lime slags. Even tungsten can be retained in remelting tool scrap if high temperatures are used. An exception to this statement is chromium, which slags readily. Of course, a large loss in manganese is to be expected—only about one-half of that added as ferro remains in the metal.

When desulphurization has proceeded well toward completion (final metal should contain but 0.015 to 0.020 per cent), the proper ferros are added to produce a correct alloy, and very hot metal quickly poured, allowed to stand in the ladle only long enough for the slag to liquate, and then poured into ingot molds. The ingots themselves are 8 in. by 14 in. in cross-section, and are cast in metal molds, split longitudinally and with the usual side lugs for clamping the halves together. A short rectangular sinkhead is placed on the mold, which is top-poured in about 50 seconds. As soon as a sufficiently strong skin has chilled on the hot ingot the molds are opened so that during subsequent cooling there may be no strains in the ingot from the shrinkage in length, top to bottom.

The teeming ladle retains no skull of any sort, a characteristic of hot electric-furnace metal, quickly cast. This is one of the main points of difference in open-hearth and electric steel—the former requires a fairly high silicon (0.20 to 0.35 per cent) to quiet the metal over a slow pouring period. Electric steel should be quiet in the furnace before tapping; silicon in it at 0.06 to 0.07 produces metal with higher physical characteristics than at the open-hearth minimum, and even this low amount is only used to produce a homogeneous metal by reducing a tendency toward segregation.

After pouring the bath, the furnace doors are opened and the lining repaired by fettling through the side doors. For this work a patented refractory—double calcined dolomite sold under various trade names—gives good satisfaction. It is banked up against the side walls in the ordinary manner, an especially large amount being required at the rear wall around No. 1 electrode, the hottest part of the furnace.

One may here remark about the present exorbitant cost of refractories in the making of highest grade electric steels. Whereas the refractory cost early in 1917 amounted to about $1.25 per ton, late in 1918, by the combined action of increase in price and decrease in quality, the cost had jumped to $5.50. Electric-furnace men will therefore naturally welcome a return to prewar conditions among the refractory makers.

Technical and trade literature often bears the statement that electric steel of the nature described in this article can be marketed in commercial quantities at a small differential over open-hearth. This is not true. The differential required today is no less than $25 per ton. With the stabilization of public service electrical supply and other industrial conditions, this spread will be narrowed, but at present even a greater increase in price is needed and is actually justified by the improved service of electric over open-hearth steel. This will become increasingly apparent as engineers fix their minds upon cost per year or cost per unit of service rather than upon first cost.

To recapitulate, the time required for one heat may be tabulated approximately as:

Charging	45 min.
Melting	2 hr. 45 min.
Dephosphoring	45 min.
Skimming	15 min.
Desulphurizing	1 hr. 15 min.
Pouring and fettling	15 min.
Total	6 hr.

Thus about four heats are produced from cold scrap every 24 hours at a current consumption of from 750 to 825 kw.-hr. per ton. Always bear in mind, however, that this figure is for a ton of high-grade steel poured. Common remelted steels or non-purified melts of inconstant composition take less current and give correspondingly less perfect results. The time of refining is materially increased by the necessity of making several chemical analyses during the last stages, especially if the furnace is to be caught and poured as the carbon or manganese is coming down. Otherwise the bath may be built up in the last stages to any desired composition. In this, metallurgical practice is not materially different from standardized open-hearth manipulation.

Pittsburgh, Pa.

Chemists' Club Scholarships

The announcement is made by the scholarships committee of the Chemists' Club of New York, that the Bloede and the Hoffmann scholarships will be awarded for the academic year 1919-1920. These scholarships were founded by Dr. Victor G. Bloede of Baltimore, and Mr. William F. Hoffmann of Newark, with the object of giving financial assistance to deserving young men to obtain an education in the field of industrial chemistry or chemical engineering.

These scholarships will be open to properly qualified applicants without restriction as to residence, and may be effective at any institution in the United States designated or approved by the scholarships committee.

Applicants must, as a minimum qualification, have completed a satisfactory high school training involving substantial work in elementary chemistry, physics and mathematics, and present a certificate showing that they have passed the entrance examination requirements of the college entrance examination board or its equivalent.

All inquiries should be addressed to the Scholarships Committee, Chemists' Club, 52 E. 41st St., N. Y.

Nodulizing Flotation Concentrates in a Rotary Kiln With Powdered Coal

By Robert M. Draper

THE rotary kiln has long been used in the cement industry, but only recently has it been utilized in the metallurgy of copper.

In September, 1912, a small 60-ft. kiln was installed at the plant of the United States Metals Refining Co. at Chrome, N. J., for the purpose of nodulizing a large accumulation of flue dust. The kiln proved a success from the start, and after the accumulated flue dust was used up, flotation concentrates were nodulized into a very satisfactory blast-furnace product. Several years later kilns were installed at Braden and operated very successfully on flotation concentrates. Both of these installations used fuel oil and at the time considerable doubt was expressed whether the operation would be successful with powdered coal on account of the low temperature required.

In 1917 the Canada Copper Corporation, Ltd., in developing its large low grade copper property at Copper Mountain, British Columbia, found that it was going to have a large amount of high grade flotation concentrates to sell and came to the conclusion that perhaps nodulizing would be of advantage. Oil for fuel was out of the question, and as there was a cement kiln in the vicinity of the mine with all the facilities for pulverizing the coal, it was decided to try some experiments with this equipment.

Two Main Problems

There were two main problems: First, to put the flotation concentrates in shape physically for the blast-furnace and second, to retain as much of the sulphur as possible. The kiln used was the usual type in cement practice, 125 ft. long and 7 ft. diameter inside of the brick work, and was in very good shape. The coal dust machinery was designed to furnish a much larger volume than was necessary for nodulizing flotation concentrates, but could be regulated fairly satisfactorily by means of a slide in the discharge pipe.

The method in use for feeding the concentrates into the kiln at Chrome had been by a screw conveyor, but this had not proved entirely satisfactory owing to choking the conveyor, and we decided to try hoisting the concentrates up to the feed end of the kiln by a bucket elevator and chuting them down into the kiln through a pipe. Owing to the original design of the plant a slope of 60 deg. was all that could be obtained for this pipe and we had more or less trouble with choking. It required a man constantly to poke the concentrates down the pipe, while the bucket elevator also gave trouble with choking.

Three Flotation Concentrates Used

For the experiments three different kinds of flotation concentrates were used: Highland Valley flotation concentrates, Highland Valley table concentrates, and Copper Mountain concentrates. Assays were as follows:

	Cu	SiO_2	Fe	CaO	S
Highland Valley flotation concentrates	19.25	19.2	18.7	2.0	18.0
Highland Valley table concentrates....	21.65	19.0	25.1	1.7	19.0
Copper Mountain concentrates.....	26.57	20.0	15.8	3.9	18.7

The copper was present in all three ores principally as bornite and chalcopyrite.

To retain as large a percentage of sulphur as possible several different schemes were tried. A spray pipe was run down into the feed end of the kiln for a distance of 6 ft. and a spray of water used to keep the concentrates as wet as possible so they would not have a chance to roast before reaching the nodulizing zone. The discharge end of the kiln was kept as nearly hermetically sealed as possible to prevent the entrance of air, but it was found extremely difficult to obtain this condition. A damper was placed in the stack and kept open just sufficiently to permit the gases to escape while keeping the kiln full of the fumes from the concentrates at all times. We found no trouble in regulating this damper so that a small amount of fume backed out of the feed end of the kiln at all times but at no time in sufficient quantity as to be obnoxious.

Best Method Not Determined

The amount of material to experiment with was not sufficient to determine which of these methods was the most satisfactory, but I am inclined to believe the damper in the stack is much the more efficient, as there can be very little tendency to draw air into a kiln that is so choked that fumes back up at both ends. Hermetically sealing the discharge end would of course give the same result, but this is very hard to do in actual practice.

How much good the spray pipe at the feed end accomplished I do not know, but I believe it would have an important bearing in reducing the dust losses.

No trouble was experienced from the start in making a very satisfactory nodule from a physical standpoint, the majority varying from $\frac{1}{4}$ to $\frac{1}{2}$ in. in diameter, and hard enough to withstand quite a sharp blow with the hammer.

Analysis of Samples

Careful samples of all tests were taken and sent to the smelter at Greenwood for analysis. These samples showed that we were retaining 70 to 80 per cent of the original sulphur. In one case when the nodules were giving off dense fumes of sulphur as they were discharged from the kiln the sample was split and half allowed to cool slowly in the air and half plunged immediately into water. The sample that was air cooled showed practically as much sulphur as that cooled in the water. This fact is important, as the nodules show a decided tendency to break up if cooled with water, but they could be readily cooled by passing them along a revolving cylinder.

The coal used was from mines in the vicinity—a rather poor bituminous coal carrying 20 per cent ash. No trouble was experienced in keeping the coal ignited, in fact several times after an hour's shut-down the coal was turned on and ignited without extra fuel of any sort.

We found no difficulty in nodulizing five tons of concentrates per hour with a coal ratio of 1 to 15.

The action all the way through was very similar to nodulizing with fuel oil. No trouble was experienced from the formation of accretions upon the walls of the kiln, and those that did form were within 12 or 15 ft. of the discharge end of the kiln, where they could be easily reached and barred off. There did not seem to be any excessive dust losses. Only 2 per cent of the amount fed settled in the chamber at the base of the stack, and the stack itself at no time gave any indications of excessive losses. There is no doubt in my mind that nodulizing in the rotary kiln with powdered coal will be as successful as in installations using fuel oil.

Southboro, Mass.

Notes on the Influence of Certain Variables Associated With the Anneal of Cold-Worked Alpha Brass

Degree of Plastic Deformation—Temperature and Time of Anneal—Rate of Heating Through the Germinative Temperature—Size and Uniformity of the Grains Prior to the Plastic Deformation—Potential Possibilities of Rolled Metal

By ARTHUR PHILLIPS* and GEORGE C. GERNER*

ONE of the first papers[1] to deal with the characteristics of recrystallization and grain growth of cold-worked alpha brass on annealing pointed out that different degrees of plastic deformation materially affected the initial temperature of visible recrystallization and also the size of the recrystallized grains. Later writers, notably Jeffries[2] and Howe[3], in discussing this paper, have presented what seem to be the main factors having a controlling influence over the mechanism of recrystallization and grain growth of pure metals and solid solutions.

It may not be out of place to review briefly the principal variables which have a pronounced effect on the mechanical properties and microstructure of commercial alpha brass on anneal subsequent to cold-reduction.

1. Degree of Plastic Deformation

In a paper[1] previously mentioned, it has been shown that different degrees of plastic deformation have a very decided influence on the temperature of recrystallization. In general, other conditions being the same, the greater the cold-reduction the lower the temperature of visible recrystallization. As evidence of this, the authors found that an anneal between 275 and 300 deg. (30 min.) following a reduction of 40 per cent sufficed to cause incipient recrystallization; the same brass reduced only 4 per cent required an anneal at 650 deg. to produce positive structural evidence of re-orientation. Furthermore, the size of the recrystallized units decreased progressively with increase in the degree of plastic deformation. Bassett and Davis, in a recent paper[5] showing the relation between the grain size and Brinell hardness of cartridge brass, have also shown that the grain size of brasses annealed at the lower temperatures is greatly affected by the degree of reduction.

2. Temperature and Time of Anneal

As stated in the preceding paragraph, the temperature of recrystallization of brass may extend over a very considerable temperature range depending upon the degree of deformation to which the metal has been subjected. Characteristic curves showing the grain size and mechanical properties as a function of the temperature (for a given reduction and constant period of anneal) show how necessary it is, from the practical standpoint, to give careful attention to the annealing temperature if specific properties are desired.

With regard to the effect of time of anneal, it is a matter of general knowledge that in the case of rather severely worked brass, i.e., corresponding to an ordinary mill reduction, the time factor is of great importance when the annealing temperature is within the range of incipient recrystallization. For higher temperatures, when approximate equilibrium conditions are rapidly attained, the question of time, between rather broad limits, is of less importance. Although this is, perhaps, a matter of common knowledge, it seems desirable to include in this paper experimental data which show the effect of time of anneal at 650 deg. on the tensile strength of alpha brass having various reductions. It is to be understood, however, that the experimental data have simply been taken bodily from the results of an investigation carried on with another objective in view. For this reason, we ask indulgence for one or two features connected with the experimental procedure which do not seem to be consistent with the subject under consideration.

For the experiments we selected from the same coil several strips of cartridge brass†, 4 in. wide and 0.185 in. thick, which had been given a uniform reduction of 43 per cent by cold-rolling in the mill. The strips were annealed together in an American gas furnace at 700 deg. for one-half hour, with a preheating period of 10 minutes. The temperature data were obtained by means of a carefully calibrated base-metal pyrometer.

Following this laboratory anneal, four strips were given mill reductions of 6.6, 15, 25 and 40 per cent respectively. Six test pieces, 8 in. by 1 in., were cut from each strip and the twenty-four bars were divided into six sets of four pieces; each set representing reductions from 6.6 to 40 per cent. The total charge was then placed in a rectangular muffle, wound with nichrome ribbon, and annealed at 650 deg. Temperature measurements were made by means of a platinum-rhodium couple, inserted in a hole drilled into the end of one strip, used in conjunction with high-resistance galvanometer. The long preheating period, 1 hr. and 7 min., was due to the mass of metal in the furnace.

A set of test bars was removed at successive intervals in the following order: end of preheating period (i.e., 1 hr., 7 min.), 15 min., 30 min., 1 hr., 2 hr. and 5 hr. After carefully milling the bars to a width of 0.50 in. over a gage length of 3 in., they were tested in a 50,000-lb. Riehle universal testing machine. The

testing data are tabulated in Table I and plotted in Fig. 1. Although we were unable to make these tests in duplicate, due to limited furnace capacity, we believe that the results are fairly reliable and significant. Samples for microscopic examination were retained, but, unfortunately, the reproduction and discussion of the micrographs is not possible in this paper.

A study of these data seems to indicate that at 650 deg. a measurable length of time is necessary to produce apparent equilibrium values for all reductions investigated. In the case of the brass reduced 40 per cent, continued annealing up to 2 hr. was attended with lower tensile strength. Since the value of the tensile strength after a 2-hr. anneal is practically identical with that found after a 5-hr. anneal, it seems reasonable to conclude that, from the practical standpoint, approximate equilibrium conditions are obtained after the shorter period. A repetition of this work will, of course, be necessary before final conclusions can be drawn regarding the effect of time of anneal on the mechanical properties of rolled brass. For this reason we do not think it advisable to enter into a lengthy discussion of the magnitudes involved, but simply offer the testing data for their possible suggestive value.

TABLE I—EFFECT OF TIME OF ANNEAL (AT 650 DEG. C.) ON TENSILE STRENGTH OF COLD-WORKED ALPHA BRASS

3. Rate of Heating Through the Germinative Temperature

Jeffries[6] has shown that in the case of pure metals and solid solutions reduced at least 15 per cent by cold-work, the grain size equilibrium (for any temperature above the equiaxing range) depends largely on the rate at which the metal passes through the equiaxing range. In general, the faster the metal is heated through this range the smaller will be the equilibrium grain size; conversely, the greater the lag in passing through the equiaxing temperature the greater the equilibrium grain size. Grain size equilibrium is defined by Jeffries as "the point where grain size either changes none or slowly." In other words, there is a small temperature range, i.e., the "germinative temperature," for every reduction at which grain growth is particularly marked. The period during which the metal is at the "germinative temperature," as remarked above, is an important factor regulating the early stages of grain growth. Although the rate of heating, in the case of alpha brass, may, under special and exceptional conditions, have an important effect on its structure and properties, yet in ordinary mill practice, which generally involves a moderately high temperature of anneal following a rather high degree of plastic deformation, considerable latitude may be allowed in the rate of heating without materially affecting the characteristics of the anneal.

4. Size and Uniformity of the Grains Prior to the Plastic Deformation

Jeffries[7] remarks in this connection that "in a given pure metal with a given amount of cold deformation, the grain size before deformation will have a marked effect on the selective grain growth during anneal. If the initial grain size is large, the grain fragments formed during annealing will be correspondingly large, and if the initial grain size is small the grain fragments will also be smaller than in the previous case." Also, "when the total average cold deformation exceeds 30 to 40 per cent reduction in area of the metal, the number of germinative grains formed during normal muffle heating may approximately equal the number of equilibrium grains for the maximum temperature reached during annealing, and thus the metal is said to be fine grained." On the other hand, if the cold deformation is comparatively slight, the local strain gradients resulting produce comparatively few germinative grains which, during the

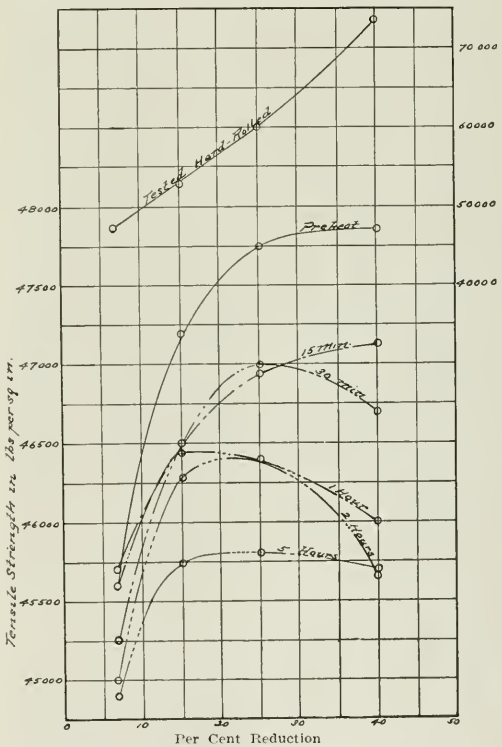

FIG. 1. EFFECT OF TIME OF ANNEAL (650 DEG. C.) ON TENSILE STRENGTH OF COLD-WORKED ALPHA BRASS

[6]Jeffries: Amer. Inst. Min. Eng., 1916, Vol. 54, p. 660.

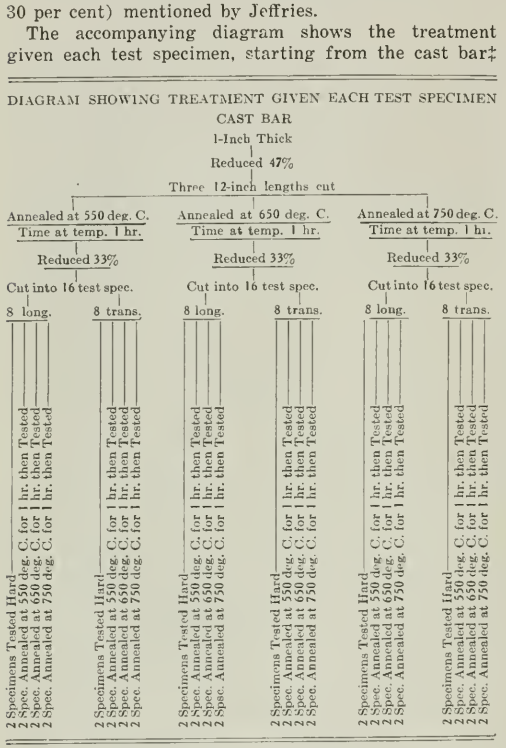
[7]Jeffries: Amer. Inst. Min. Eng., 1916, Vol. 56, p. 575.

subsequent anneal, attack and absorb the inert grains. Such treatment tends to favor "selective grain growth" and is characterized by coarse crystallization.

In order to learn the influence of the grain size prior to the plastic deformation on the microstructure and mechanical properties of rather severely worked alpha brass annealed under conditions comparable to mill practice, the following experimental work was undertaken. It should be noted that the reduction given the metal used in this investigation exceeded the minimum value (i.e., 30 per cent) mentioned by Jeffries.

The accompanying diagram shows the treatment given each test specimen, starting from the cast bar‡

DIAGRAM SHOWING TREATMENT GIVEN EACH TEST SPECIMEN



(1.0 in. thick) to the testing of the pieces. As indicated by the diagram, the cast bar was reduced 47 per cent, cut in 12-in. lengths, three of which were used for this experimental work. One piece was annealed at 550 deg., another at 650, and the third at 750. In all cases the period of anneal was 1 hr.; the preheat period varied from 15 to 40 min. All anneals were made in an American gas furnace. After the anneals the strips were reduced 33 per cent by cold-rolling in the mill. Each piece was then cut into sixteen test specimens, eight in the direction of rolling and eight at right angles to the direction of rolling. This gave six lots of samples, eight in each lot. All strips were milled so as to give a test section 4¼ in. long, with a cross-sectional area 0.625 in. times the thickness of the metal (0.355 in.).

Each lot was again divided into four sets, two to a set. One set from each lot was tested hard; the remaining three sets were annealed for 1 hour at 550, 650 and 750 deg. respectively. A piece for microscopic examination was cut from the end of each test piece.

‡Analysis: Copper, 70.33; iron, 0.018; lead, 0.005 per cent.

Tensile and hardness tests were made on each specimen. The scleroscopic tests were made with a Shore instrument; an Olsen (hydraulic type) machine was used in determining the Brinell hardness. Two indentations were made on each test piece, one at each end, and the average value given. The indentations on the unannealed test pieces were, of course, elliptical. For this

reason, the axis parallel to the direction of rolling was measured on the longitudinal test pieces; the axis normal to the direction of rolling was measured on the transverse pieces. Tensile tests were made on a 50,000-lb. Riehle universal testing machine. In addition to the tensile strength determinations, values for the per cent elongation and per cent reduction in area were obtained.

Results of the Tests

Table II shows the results of tests made on specimens taken in the direction of rolling; Figs. 2 and 3 present the same data in plotted form. Table III gives the results of tests made on test pieces taken normal to the direction of rolling. As the transverse tests of the annealed samples agreed so closely with the values obtained on the longitudinal tests, it did not seem necessary to plot the results shown in Table III. The average values obtained on the unannealed test pieces, longitudinal and transverse, are given again in Table IV in order that they may be readily compared. It will be noted in Figs. 2 and 3 that the curves show the physical properties as a function of the anneal before the final reduction, instead of the final anneal as is the common practice.

TABLE IV—DIRECTIONAL PROPERTIES OF ALPHA BRASS REDUCED 33 PER CENT BY COLD ROLLING SUBSEQUENT TO ANNEAL AT 550, 650 AND 750 DEG. C., RESPECTIVELY

Temperature of Anneal, Deg. C.	Tensile Strength, Lb. Sq.In.	Per Cent Elongation in 2 In.	Per Cent Reduction of Area
550 Longitudinal	75,650	18.25	51.8
550 Transverse	78,000	11.5	25.1
650 Longitudinal	74,850	18.0	52.6
650 Transverse	75,300	11.0	30.0
750 Longitudinal	67,950	24.0	52.1
750 Transverse	68,200	12.0	25.5

Transverse test bar....	0.620x0.355	0.2200	15,570	70,750	11.0	31.6
Transverse test bar....	0.624x0.355	0.2215	15,620	70,500	12.0	31.7
Average				70,650	12.8	32.9

Tensile tests on the annealed samples indicate that while the grain size before the final reduction has some influence on the mechanical properties of the annealed brass, the magnitude of the effect is small, especially in metal annealed at the higher temperatures. It will be

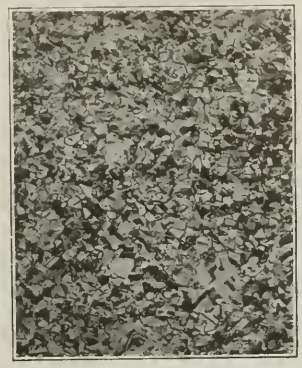

Fig. A. One hour at 550 deg. C.

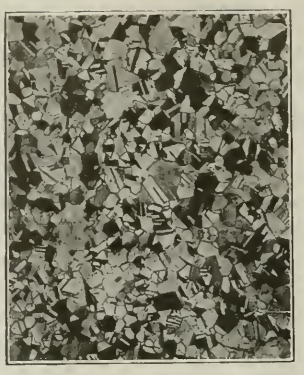

Fig. B. One hour at 650 deg. C.

PLATE I

Etched with ammonia and hydrogen peroxide. × 50. Cartridge brass (copper, 70.33; lead, 0.005; iron, 0.018 per cent). Effect of anneal after 47 per cent reduction by rolling.

seen from Fig. 2 that the tensile strength curve for 750 deg. final anneal is almost horizontal, indicating that for this anneal the tensile strength is, within certain limits, independent of the previous grain size. The Brinell hardness curve of Fig. 2 and the crystal count curve of Fig. 3 for the same anneal also show very little change, but the curve for per cent elongation in Fig. 3 slopes upward, which seems to indicate that large initial grain size tends to increase the elongation. The same relation seems to hold for the lower temperature final anneals as indicated by the elongation curves of Fig. 3, all of which show about the same slope. In the lower temperature anneals, the smaller initial grain size seems to yield finer grain fragments upon subsequent anneal, as is shown by the crystal count curves in Fig. 3. The tensile strength is also increased as would be expected from the finer grain produced by the anneal.

An examination of the micrographs shown in Plates I, II, III and IV seems to indicate that the grain size prior to reduction is one of the important factors affecting the final grain size. The samples annealed at the higher temperatures show considerable variation in grain size within the individual specimens. This type of structure, as shown by Fig. C, Plate III, and Figs. A, B and C, Plate IV, is quite characteristic of commercial brass. In view of the difficulty of obtaining grain counts with a high degree of accuracy, it does not seem advisable to subject the grain count curves of Fig. 3 to critical analysis. It is evident, however, that in all cases the grain size after all final anneals (i.e., 550, 650, 750 deg.) increased progressively with increase in temperature of the anneal prior to the reduction.

Ductility

As has been previously stated, the annealed brass when tested longitudinally and transversely showed no directional properties; the rolled metal, however, when tested showed that the longitudinal test pieces yielded the higher values of ductility. These values are given in Table IV, from which it will be seen that although the tensile strength is practically the same, there is a very marked difference in the per cent elongation and the reduction of area. The tests become especially intresting when compared with the values given by Price and Davidson[8] for similar tests on common high brass

[8]Price and Davidson: "Physical Tests on Common High Brass Taken Parallel and at Right Angles to the Direction of Rolling" Amer. Inst. Metals, 1916, Vol. 10, p. 133.

which had received approximately the same reduction. In this connection they state that "up to 35 per cent reduction by rolling the elongations for both kinds of strips are practically identical. But from there on the transverse specimens show marked superiority."

Since our results were contradictory to this conclusion we annealed another piece of the same bar at 680 deg. and gave it the same reduction, i.e., 33 per cent, after which three longitudinal and three transverse tests were made. The results of these tests are given complete in Table V, and it will be seen that here again the elongation and reduction of area are higher for the longitudinal samples than for the transverse. Although Price and Davidson found no difference at 33 per cent reduction, they found that the elongation was less in longitudinal than in transverse tests in the samples which had been reduced above 35 per cent. This is not in agreement with our results.

Possibly the following explanation may account for the higher ductility of the longitudinal test pieces. Due to the compressive action of the rolls, plastic deformation takes place by means of a series of slips along a large number of gliding-planes or cleavage-planes, most of which are at right angles to the direction of grain extension. The characteristic lines of deformation found in cold-worked brass are very prominent in Price and Davidson's micrographs.

In explaining their results Price and Davidson attributed the poorer ductility of the longitudinal test bars to the fact that the planes of slip (at right angles to the tensile stresses) had been utilized during the rolling operation. When making the transverse tests, however, a large number of gliding-planes would be available, since comparatively few had been utilized during the rolling operation. For this reason, they believed that the transverse test bars should give the greater elongation.

In order to explain the contrary results obtained by us, we would offer a suggestion with regard to the potential possibilities of the rolled metal. Fig. 4 (on the left) represents a test bar cut from metal at right angles to the direction of rolling. Within the individual grains, and chiefly parallel to the length of the test bar, are a very large number of lines of deformation which are indicative of plastic deformation by slip. If, as it is quite generally believed, movement by slip generates amorphous material along the gliding-planes, the test piece is reënforced by innumerable plates of amorphous

Fig. A. One hour at 750 deg. C.

Fig. B. One hour at 750 deg. C.

material of a low order of ductility. It seems reasonable to conclude, therefore, that the presence of these plates would tend to lower the ductility of the mass as a whole when subjected to a tensile force.

Fig. 4 (on the right) represents a test bar cut from the metal parallel to the direction of rolling. In this case the amorphous planes are at right angles to the length of the test section. Although slip has taken

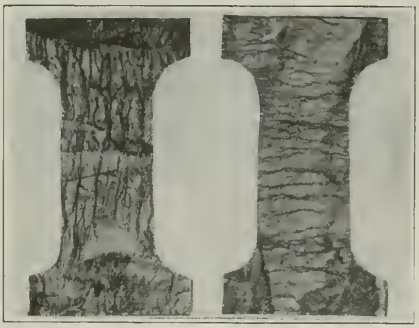

FIG. 4. TEST BAR CUT AT RIGHT ANGLES TO DIRECTION OF ROLLING (LEFT). CUT PARALLEL (RIGHT)

place along a large number of gliding-planes during the rolling operation, there must still remain a very considerable number of gliding-planes along which movement can take place when the bar is subjected to tensile test. That this is true is indicated by Price and Davidson's micrograph, Fig. D, Plate IV, showing the structure of the test piece which had been reduced approximately 80 per cent without fracture.

In other words, we believe the distribution of the amorphous material in the longitudinal test bars is more favorable to extension under tension in the transverse test bars.

In this connection the experimental results given by Price and Davidson do not seem to be at all consistent with their statement: "It is common knowledge that in a cold bend test, a piece of very hard brass can be bent several times through 180 deg. when tested longitudinally. The same specimen when bent transversely will fail before it passes through an angle of 90 deg."

Effect of Sodium Chloride on Blue-Powder Formation

By Reginald S. Dean

IT IS common practice in zinc metallurgy to add small amounts of salt to the charge, which has been definitely found to reduce the amount of blue powder formed. No satisfactory explanation has been offered, however, for this action of sodium chloride, and we are therefore not in a position to develop any improvements in this method of preventing blue-powder formation.

The only text-book which discusses or even mentions the use of salt in Lodin, Metallurgie du Zinc (p. 163). The first patent granted for its use was that of Dony (French, Dec. 7, 1809), which called for a mixture of salt, chalk and potassium carbonate in the proportions of 1.4 per cent of the weight of ore NaCl, 4.1 per cent $CaCO_3$ and 0.2 per cent K_2CO_3. Later practice has reduced the proportion of salt to 1 per cent or less.

Volatilization of sodium chloride is evident from the first of the operation nearly to the end, and can be easily detected by the yellow flame. If the furnace is equipped with prolongs, a small amount of zinc chloride can frequently be found condensed in them, or if an excess of salt is added it is sometimes found in a layer of zinc chloride over the spelter.

Various hypotheses have been offered to explain the action of sodium chloride. These assume either a physical effect due to the entrainment of zinc vapor with the vapor of sodium chloride or a solution by the zinc chloride of any oxide coating formed on the condensed zinc particles. Although these may be contributing factors, the observations of Kiessling (*Berg. u. Hutt. Ztg.*, 1903, p. 613) have shown that sodium carbonate acts similarly to the chloride, though perhaps not quite so effectively. Since sodium carbonate is non-volatile and no zinc chloride can be formed, we must look for other explanations. A hypothesis is offered here which, though not free from objections, offers a basis for rational development.

The formation of blue powder is due to a reoxidation of the zinc by the carbon dioxide existing in the condenser according to the reversible reaction $ZnO + CO \leftrightharpoons Zn + CO_2$. Researches by the American Zinc, Lead & Smelting Co. show quite conclusively that the percentage of carbon dioxide in equilibrium with a given mixture is greater at high than at low temperatures.

The presence of salt may be supposed to modify the reaction between ZnO and carbon thus:

$$2NaCl + ZnO + C \leftrightharpoons 2Na + ZnCl_2 + CO$$

The amount of sodium chloride which reacts in this way is only a small percentage of the whole, the principal portion volatilizing as such. If the amount of zinc chloride formed is not large, it escapes from the condenser unnoticed, since the blue zinc flame is masked by the yellow of sodium. It also collects to some extent in the blue powder that is formed. The metallic sodium, being volatile, passes off with the zinc, and is the effective agent in reducing blue-powder formation, it does this by reducing the CO_2 content as the temperature falls, so that the sodium instead of the zinc is oxidized. Considering the two reactions,

$$2Na + CO_2 \leftrightharpoons Na_2O + CO$$

$$\frac{C^2_{Na} \times C_{CO_2}}{C_{CO}} = K'$$

$$Zn + CO_2 \leftrightharpoons ZnO + CO$$

$$\frac{C_{Zn} \times C_{CO_2}}{C_{CO}} = K''$$

K' is smaller than K'', and hence the sodium is oxidized and the zinc protected. Sodium carbonate would obviously effect the same result since the reaction

$$Na_2CO_3 + 2C \longrightarrow 2Na + 3CO$$

is known to proceed at fairly high temperatures. It has the advantage of being non-volatile and producing no zinc chloride, hence causing no zinc loss from this source. Sodium carbonate, however, tends to form slag, hence is objectionable. It should be noted that spelter made with the use of sodium chloride usually contains traces of metallic sodium, which can readily be detected by the flame test.

Thus a substance to be effective in reducing blue-powder formation must contain a volatile element more easily oxidized than zinc.

Anaconda, Mont.

Fusibility of Ash From Pennsylvania Coals*

By W. A. Selvig and A. C. Fieldner

PREVIOUS papers[1] gave a description of the standard gas-furnace method used by the Bureau of Mines in making ash-fusibility tests, a discussion of the relation of fusibility tests to clinker formation and tables giving a summary of results obtained for the coals of West Virginia and the Interior Province. This paper includes a table giving a summary of such tests on the coals of Pennsylvania, which State is by far the greatest coal-producing state in the Union.

Interpretation of Fusibility Table

The various coal beds of the bituminous coal field of Pennsylvania are arranged according to their geological succession, the uppermost beds being listed first. The samples are practically all standard mine samples collected according to the methods used by the Bureau of Mines.[2] A few car samples which were considered representative of the output of the various mines were also included.

The various coal districts of the anthracite region are arranged alphabetically under the field to which they belong. The samples are practically all delivery samples of the various sizes as marketed, only a few standard mine samples are represented.

FUSIBILITY OF COAL ASH FROM PENNSYLVANIA COALS

Series, Bed	Number of Mines Sampled	Total Number of Samples	Average Softening Temperature, Degrees F.	Ash in Dry Coal, Average Per Cent	Sulphur in Dry Coal, Average Per Cent
BITUMINOUS REGION					
MONONGAHELA SERIES					
Pittsburgh Bed	10	34	2360	7.17	1.43
CONEMAUGH SERIES					
Little Pittsburgh Bed	1	2	2390	8.13	1.70
ALLEGHENY SERIES					
Upper Freeport (E or Lemon) Bed	33	85	2350	9.35	2.13
Lower Freeport (D or Moshannon) Bed	21	70	+2390	8.52	2.06
Upper Kittanning (C Prime) Bed	7	18	+2350	8.67	2.16
Middle Kittanning (C) Bed	5	7	+2380	11.06	2.98
Lower Kittanning (Miller or B) Bed	39	162	+2550	7.86	2.03
Fulton Bed	4	12	+2940	7.36	1.18
Brookville (A) Bed	3	3	+2800	12.98	1.86
POTTSVILLE SERIES					
Bloss Bed	3	3	2630	11.96	2.25
ANTHRACITE REGION					
Northern Field					
Pittston District	1	1	+3010	6.03	0.58
Plymouth District	2	7	+3010	12.52	0.84
Scranton District	6	7	+3010	12.39	0.79
Wilkes-Barre District	3	4	+3010	13.17	0.78
Eastern-Middle Field

West Mahony District	3	3	+3010	.....	....
Southern Field					
East Schuylkill District	2	2	2990	11.19	0.78
West Schuylkill District	1	1	2730	18.07	0.82

NOTE.—A plus sign (+) placed before a given value denotes that the true value is above that indicated.

Values and Softening Temperatures

The number of mines sampled, number of samples represented, average softening temperature in degrees F., per cent ash and per cent sulphur on the dry coal basis are given for each bed tested in the bituminous coal field, and for each district in the anthracite region. Average values for each mine were computed from the individual samples, and from these values averages representing each bed or district were obtained. In some instances the average values given for the beds or districts represent only a few mines and are in such cases not truly representative. The point taken as the softening temperature is that at which the ash when molded into solid triangular pyrimids $\frac{3}{4}$-in. high and $\frac{1}{4}$-in. wide at the side of the base and mounted in a vertical position has fused down to a spherical lump. Samples remaining unfused at 3010 deg. F., which was the highest temperature attained in the test, were marked plus 3010 (+3010) and used as such in figuring the average values for the mine from which the average values of the beds or districts were computed.

Discussion of Fusibility Values

As stated in a previous paper[1] on the fusibility of coal ash from the Interior Province coals, the softening temperature of coal ash from the various fields of the United States ranges in general from 1900 to 3100 deg. F. This range of softening temperature for convenience in discussion is subdivided into the three following groups:

Class 1, refractory ashes, softening above 2600 deg. F.

Class 2, ashes of medium fusibility, softening between 2200 and 2600 deg. F.

Class 3, easily fusible ashes, softening below 2200 deg. F.

The softening temperature of the ash from the bituminous coal field of Pennsylvania are found in Class 1 and Class 2, principally in the latter. The beds of the Monongahela, Conemaugh and Allegheny series, with the exception of the Lower Kittanning, Fulton and Brookville beds of the Allegheny series, are very uniform as regards to fusibility and come in Class 2. The Lower Kittanning bed of the Allegheny series contains a large number of mines which give ash of high fusibility, and the average for this bed almost places it in the lower part of Class 1. The Fulton and Brookville beds of the Allegheny series, as also the Bloss bed of the Pottsville series, come in Class 1.

Older Beds Show High Softening Temperatures

It is interesting to note that the coals that show high softening temperatures are geologically the lower and older beds of the bituminous coal field. This was also found to be true of the coal beds of West Virginia. It has been found that in general the beds of the Monongahela and Allegheny series of Pennsylvania give a more refractory ash than do the same beds as found in West Virginia.

The ash from the anthracite region of Pennsylvania is very refractory, coming in Class 1. The softening temperature in practically every instance is above 3000 deg. F.

Commercial Feasibility of Electric Smelting of Iron Ores in British Columbia*

Markets for Iron and Steel—Available Ore, Concentration of Low-Grade Magnetites—Cost of Electric Current Compared With Coke and Charcoal Reduction — Electrodes, Types of Furnaces—Cost of Plant and Smelting

A BRIEF abstract of Dr. Stansfield's main conclusions from his recent studies in British Columbia has already appeared in the columns of this journal (CHEMICAL & METALLURGICAL ENGINEERING, Vol. 20, p. 206, March 1, 1919). Appendices to his report constitute the bulk of its volume, containing material of large value to students of electric smelting, as well as shedding light upon the Western market for electric iron and steel.

MARKETS FOR IRON AND STEEL

Considerable divergence in opinion is recorded as to the British Columbian market for foundry pig iron—the most sizable outlet for simple furnace products. This is partially due to the fact that recent shortages and high prices have caused a considerable curtailment in custom founding, while recent shipbuilding is responsible for a large specialized output. During the year ended March 31, 1915, but 2341 tons of pig iron entered the ports of British Columbia and Alberta. Some probably was shipped from Eastern Canadian works, while considerable quantities of scrap are normally used in cupola work. This unquestionably augmented the supply, for 2341 tons of pig would be consumed in one sizable foundry in a month. Various men connected with the metal trades estimated that from 10,000 to 15,000 tons of foundry iron could be absorbed annually in British Columbia (apart from the shipbuilding industry) if the price could be made from $30 to $40 per ton, instead of the $60 to $70 ruling during the summer of 1918.

"Before the war, with Eastern prices about $15 per long ton, the price in British Columbia would be between $25 and $30. While it is impossible to predict the course of prices after the war, it seems likely, in view of the high cost of living and the increasing powers of the working-classes, that the price of labor, and consequently the price of manufactured products, will not return again in the near future to the pre-war figures. If we may assume that Eastern prices of pig iron will not fall below $20, it will follow that the normal price of pig iron in British Columbia will not fall below $35, or at the lowest price $30, for a period of several years.

"With regard to the possibility that a blast-furnace plant may be established in the State of Washington, and that it may capture the market for iron in British Columbia, I may state that the B. L. Thane Co. estimates the cost, under 1918 conditions, of making iron in the State of Washington at $22, $26 and $30, on three assumptions with regard to the cost of supplies. Taking the middle estimate, $26, and adding the freight, say $2, and the Canadian duty of $4.75, would raise the cost of iron delivered in British Columbia to about $33; a figure which is about the same as the cost of making electric-furnace iron with power at $15. The bounty offered by the British Columbia government would, apparently, turn the scale in the favor of the electric product. After the war the war duty of 7½ per cent *ad valorem* will no doubt be withdrawn, and in general we must expect that a blast-furnace plant on the Pacific coast would be able to take a part at least of the market in British Columbia for the cheaper grades of iron, but, with the help of the Canadian duty and the Provincial bounty, an electric smelting plant in British Columbia should be able to retain the local market for the higher grades of iron."

On account of the limited market for pig iron—which Dr. Stansfield estimates as 20 to 30 tons daily (at a price of $35), the recommendation is for a small electric plant which can produce steel and ferros as well.

AVAILABLE ORE

The report goes into the available ore supply in considerable detail. With no iron furnaces operating in the western region, it is only natural that none of these deposits are developed. However, some large ore bodies near tidewater have been prospected with sufficient thoroughness to warrant the opinion of competent geologists and mining engineers that several million tons of 55 per cent magnetite, low in phosphorus and sulphur, can be easily delivered at tidewater furnaces at a cost of approximately $4 per ton.

CONCENTRATION OF LOW-GRADE MAGNETITES

It is pointed out that it will oftentimes be cheaper to eliminate gangue mechanically than to slag it, especially by expensive electrical heat in a small furnace. As an instance, it is assumed that "the ore can be mined to contain 40 per cent of iron at a cost of $1 per ton, where the 50 per cent ore cost $2 to mine. Adding the fixed charge of 10c. and the royalty of 40c. (50c. for a 50 per cent ore), the crude ore will cost $1.50 per ton. The crushing to 80 mesh and magnetic concentration may cost 80c. per ton, making a total of $2.30. Suppose that 2 tons of ore yield 1 ton of a 70 per cent concentrate, then the cost will be $4.60 per ton of concentrate. To this we must add a charge of, say, $1 for sintering and $1 for freight, making a total of $6.60 per ton. This corresponds to $9.45 per ton of pig iron, which is $1.45 more than the cost using raw 50 per cent ore at $4 a ton. The saving in the smelting process, due to the use of a richer ore, would be in the order of $3 a ton of iron, thus making a saving of about $1.55 per ton."

On the other hand, Dr. Stansfield thinks it would not be advisable to dress a 50 per cent ore up to 65 per cent, if it involved sintering the concentrate. As a matter of fact about 25 per cent of fine concentrated ore (so-called "slig") is used in Swedish practice, while it

*Excerpts from Bulletin No. 2, 1919, British Columbia Department of Mines, by Alfred Stansfield, D.Sc., Professor of Metallurgy, McGill University.

would be the exact material required for a metallizing operation.

"The possibility of the commercial operation of an electric-smelting plant for the production of pig iron from iron ore depends on an adequate supply of electric power at a moderate rate. A large amount of power is needed, the amount varying somewhat with the richness of the ore, the grade of iron to be produced, and the kind of furnace employed. Under usual conditions the consumption of electrical power for each long ton of pig iron lies between one-third and one-half of a horsepower-year. For the production of foundry iron from rather low-grade ores, and in a simple pit furnace, it will not be safe to count on the production of more than 2 long tons of iron per annum for each eleectric horsepower supplied to the works. For a production of 50 tons of pig iron daily some 8000 or 9000 electric horsepower will be needed, and if provision is made for the production of ferro-alloys and the making of steel in electric furnaces, some 10,000 to 15,000 hp. must be provided.

Cost of Electric Power for Smelting

"The power companies in Vancouver were unable, during my visit, to give me definite information on this point, but I understood that power could probably be provided at about $15 per electrical horsepower-year; a price at which it seemed possible that electric smelting could be undertaken commercially. When my report was nearing completion, I received a letter informing me that the charges for electric power would be nearly twice the figure I had assumed in my calculations. Under this changed condition the electric smelting of iron ores by existing methods is scarcely possible, and the only remaining opening, unless cheaper power can be obtained, is by developing a new process."

So much for the commercial current already available. It appears that there is ample undeveloped power going to waste, and Dr. Stansfield was furnished estimates showing that 340,000 hp. at three accessible points could be developed for smelting purposes at about $10 per horsepower-year.

Such costs would be lower than for ordinary users, since the load factor would easily approach 90 per cent. "The power factor of these furnaces has been found to be very high in Sweden, where the supply is one of 25 cycles, but in California, using a 60-cycle supply, the power factor of the [open pit] furnace has been found to vary from nearly unity when the furnace is empty to as low as 65 per cent when the furnace is ready for tapping. I should think, however, that if special attention were paid to this side of the design of furnace, it could be made to keep the power factor above 80 per cent at all times. Voltage regulation is effected by a series of taps on the primary of the service transformers, there being usually three such transformers for each furnace, which are independently regulated. On account of this the transformers are of special design, and the primary voltage would not be more than about 10,000, and preferably in the order of 2000.

"It will be understood that such development [of new power houses] would be out of the question at the present time in view of the high cost of labor and supplies, and the difficulty of obtaining apparatus.[1] It seems probable, however, that within a few years after the termination of the war, wages and costs in general will arrive at some more settled condition."

[1]The report was dated Nov. 11, 1918.

Up to ½ ton of charcoal or coke is needed for the reduction of a ton of pig iron, charcoal being preferred for its greater purity, its higher electrical resistance preventing short circuiting at the top of the charge, and its friability producing intimate contact between ore and reagent.

"Theoretically, 1 ton of foundry pig iron will need 0.269 ton of carbon for its reduction from magnetite and about 0.035 ton for its carburization, assuming it to contain 3.5 per cent of carbon. It will also need 0.026 ton of carbon for the reduction of 3 per cent of silicon. The combined carbon requirement will thus be 0.33 ton per ton of pig iron. On account of the well-known purity of wood charcoal, it is often assumed that it contains at least 90 per cent of carbon, and that some 0.38 ton of charcoal will be sufficient per ton of pig iron. Actually, however, charcoal contains from 70 to 75 per cent of fixed carbon; the average over a long period in Sweden being 73 per cent, the balance being volatile matter and moisture, and accordingly some 0.44 to 0.47 ton of charcoal must be provided. In view of the custom of weighing iron by the long ton and charcoal by the short ton, it appears that ½ net ton of charcoal will be required. There is, indeed, a small amount of reduction by carbon monoxide, even in the open furnace, but this will be balanced by the combustion of charcoal at the top of the furnace and the other mechanical losses. Assuming that 5 per cent of the carbon monoxide is utilized in the open furnace and 25 per cent in the Swedish furnace, we find that 0.4 net ton of charcoal should be enough in the latter type of furnace. Mr. Gronwall, in his estimate, quoted in my report on 'Electrothermic Smelting of Iron Ores in Sweden,' allows 0.370 metric ton of charcoal per metric ton of foundry iron, and this would be 0.414 net ton per long ton of pig iron. It will be seen, therefore, that my estimate is supported both by theoretical calculations and by the results of practice in Sweden.

Comparison of Coke and Charcoal

The comparative values of these as reducing materials depend in the first place on their fixed-carbon content. Thus, if charcoal contains 73 per cent of fixed carbon and coke 84 per cent, the coke would appear to be the more valuable. The remainder of the charcoal, however, is volatile matter and moisture, which is driven off harmlessly in the furnace, while the coke would contain some 13 per cent of ash, which has to be melted, and will usually necessitate the addition of a flux. The sulphur in the coke also will need fluxing, in addition to lowering the purity of the resulting pig iron. It follows, from these and other considerations, that charcoal is somewhat more valuable than coke as a reducing reagent. Referring to Mr. Gronwall's estimate in my Swedish report, the following figures show the relative consumption of fuel and of electric power for 1,000 kg. of pig iron, according as charcoal or coke is employed:

TABLE I. REDUCER AND ENERGY FOR SWEDISH FURNACE

	Using Charcoal of 73 Per Cent Carbon		Using Coke of 85 Per Cent Carbon	
	Kilos Fuel	Hp.-Year	Kilos Fuel	Hp.-Year
White pig iron	340	0.37	370	0.39
Gray pig iron	370	0.40	400	0.42

"At the present time no considerable quantity of charcoal is produced in British Columbia, and its price is now $30 a ton. However, large quantities of Douglas fir mill waste are available and suitable for carbonizing in charcoal-kilns, the yields in by-products being unimportant.

"The regular charcoal-kiln is a circular brick structure holding about 50 cords of wood. It is charged and discharged by hand, and the volatile by-products are partly saved by being drawn through condensers, the permanent gases being returned and burnt in the kiln. If a battery of these kilns were established at a large lumber-mill so that the waste wood could be delivered mechanically to the kilns, the production of a ton of charcoal might cost:

2½ cords of mill-waste at $1	$2.50
Labor and other expenses of operation after deducting the value of the by-products	2.50
Carriage of charcoal to smelter	1.00
Total	$6.00

"For the electric-smelting plant about 40 tons of charcoal would be needed daily. Each kiln would yield 20 tons, but as the process is slow, requiring about fifteen days, some thirty kilns would be required. If a charcoal industry were established in suitable relationship to the lumber industry, charcoal could be delivered to the smelter at a cost of about $6 or $8 per ton, corresponding to $3 or $4 per long ton of pig iron.

Electrodes

"The electrodes used in the Swedish furnaces at the time of my visit in 1914 were 24 in. in diameter and 4 or 5 ft. long. They were provided with threaded ends, so that fresh lengths could be added as the electrodes wore away. They were of amorphous carbon and cost about 4c. per lb. The consumption of electrodes, when making white pig iron from high-class ores, was about 10 to 15 lb. per ton of pig iron, thus costing about 50c. per ton of product. In melting lower grade ores for foundry iron the consumption might be from 15 to 20 lb.; at present prices in British Columbia this would mean about $1.50 per ton of pig. A furnace of 3000 kw. uses six of these 24-in. electrodes.

TABLE II. BECKMAN AND LINDEN'S ESTIMATE OF COST

300-Ton-per-Month Electrode Plant

Baking kilns complete, including all burning apparatus	$20,000
Hydraulic press (500 tons per month, 600-ton pressure)	6,000
Two mixers	6,000
Molds	5,000
Calciner complete	40,000
Building complete	25,000
Crane	8,000
Conveying equipment and elevators	2,500
Crushing and screening apparatus	3,000
Kiln-sand	1,000
Tools, chain, etc	1,000
Contingencies, 10 per cent	11,850
Engineering	15,000
Total	$144,350

Cost of Making 2000 Pounds of Electrodes

Anthracite coal, calcined, crushed and sized	$20.00
Pitch at $20 per ton	5.00
Baking fuel, pound per pound ratio	4.50
Labor, 50c. per hour	12.75
Operating superintendence	1.85
Supplies	1.00
Maintenance	2.00
Plant office expense	.75
Main office expense	4.00
Total	$51.85
Cost per lb., 2.6c.	

"At Bay Point, Cal., the 3,000-kw. open-pit furnace, smelting ferromanganese, uses three 24-in. carbon electrodes. The consumption is 100 lb. per ton of ferromanganese, and Beckman and Linden expect that in using this furnace for making pig iron the consumption would be 20 lb. per ton.

"Under ordinary conditions carbon electrodes cost 3c. or 4c. per lb. [see Table II], but at the present time the price in the East is about 8c., and on the Pacific coast nearly 10c. It is desirable to make electrodes locally, but this should not be undertaken until the smelting plant is in good running order."

"There is a fair supply of laborers at nearly $4 a day, and most skilled men are scarce at about $6 a day. The cost of labor per ton of iron depends very much on the size and output of the plant. Thus, in a fully equipped plant making 50 or 60 tons of pig iron, and steel and ferro-alloys as well, the cost of labor might be $4 or $5 per ton of iron, but if only one or two furnaces were operating the labor cost might be about $7 per ton of iron.

"At Hagfors three 3000-hp. furnaces are operated by fifty men, working 8 hours daily, at a wage of about 12c. per hour. At this rate, with bonuses and the higher rates of foremen, the cost would amount to about 80c. a ton of pig iron. In a plant of three 3000-kw. furnaces in British Columbia fifty men might be assumed to cost: Thirty at $4 and twenty at $6, or $240 a day. With an average output of 75 tons daily of foundry iron this would mean $3.20 per ton. A plant of this size would probably need a few additional men, say ten or twelve, which would increase the charge for labor to about $4 a ton.

TABLE III. DAILY LABOR FOR ONE 3,000-KW. PIT FURNACE

One furnace foreman at $8	$8.00
Twelve furnacemen at $5	60.00
One chief electrician at $6	6.00
Three sub-station operators at $5	15.00
Three mechanics at $6	18.00
Six mixing-men at $4	24.00
Six metal-handlers at $4	24.00
Two locomotive-crane men at $5	10.00
Total	$165.00

"With an output of 25 tons per day this would mean $6.60 per ton of iron."

Type of Furnace

1. *Electro-Metals Furnace Used in Sweden.* This furnace has been described repeatedly—for instance, in Dr. Stansfield's book, "The Electric Furnace," 1914 edition, pages 174-211—and is doubtless familiar to most readers. It consists of a furnace shaft, quite similar to an ordinary small iron blast-furnace stack, independently supported above a relatively shallow crucible of larger diameter, the latter covered with an annular arch through which project the electrodes. Furnace gases are ordinarily recirculated through tuyeres between the roof of the crucible and the descending charge, both to cool the roof and preheat the content of the shaft. Typical analyses of pig irons made in large tonnage in Sweden (Hagfors?) are:

	For Open-Hearth	For Lancashire Treatment	For Bessemer
Si	0.4 to 0.6	0.2 to 0.3	1.0 to 1.4
Mn	0.3 to 0.5	0.2 to 0.3	2.5 to 3.0
P	0.011 to 0.018	0.011 to 0.018	0.015 to 0.019
S	0.015	0.015 to 0.020	0.005

During the early operation of the plant there was a tendency for the sulphur to be unduly high, but this was remedied by making the slag more basic whenever the furnace was run for Lancashire pig.

Excellent bessemer has repeatedly been made. The early attempts were not good, but it was soon found that Si and Mn had to be increased. It had been assumed that the amount would be normal, but apparently the lower temperature of the electro-bessemer pig as compared with ordinary bessemer pig from blast-furnaces necessitates a higher content.

General experience points to the following results: It

is cheaper to make spiegel than gray pig, because: (1) More current can be put through the furnace; (2) the current consumption is lower (per ton of product); (3) thus the production is higher; (4) the electrode consumption is lower; (5) the repair costs are lower.

It may further be stated that rich charges give better economic results than poor ones. The quality of the pig, however, is not influenced by the percentage of iron content of the ore.

For some time past the gas from the furnaces has been used as fuel in the open-hearth furnaces, and it is estimated that the value of the gas is from 50c. to 75c. per ton of pig iron produced.

In large plants white pig can be made from 65 per cent ore with 0.31 hp.-yr. per ton, or gray pig with 0.37 hp.-yr. per ton. Smaller plants on account of a greater "diversity factor" would require perhaps 0.41 hp.-yr. per ton of gray iron, or 0.45 hp.-yr. if the ore ran not over 55 per cent iron.

The following furnaces of this style have been constructed:

SWEDEN

Trollhatten,	one 2250-kw. furnace; one 3000-kw. furnace.
Hagfors,	two 2250-kw. furnaces; three 4,000-kw. furnaces.
Domnarfvet,	one 7000-kw. furnace; four 3000-kw. furnaces, one 2000-kw. furnace.
Soderfors,	one 5000-kw. furnace.
Ljusne,	one 3000-kw. furnace.
Porjus,	two 3000-kw. furnaces.
Lulea,	three 3000-kw. furnaces.

NORWAY

Tyssedahl (Hardanger), two 2600-kw. furnaces.
Arendal, two 2000-kw. furnaces.

SWITZERLAND

Two furnaces.

JAPAN

Three furnaces.

ITALY

Aosta, six 3000-kw. furnaces.

2. *Helfenstein Furnace.* "The Helfenstein furnace was originally devised for the production of calcium carbide and ferrosilicon. [See R. Taussig, MET. & CHEM. ENG., X., 1912, page 686.] A 10,000-hp. furnace of this type for iron-smelting was started at Domnarfvet in May, 1913. A more recent account appeared in MET. & CHEM. ENG., May 1, 1917, page 509, from which I have taken the following particulars:

"When charcoal was used, the consumption of power, etc., was 2170 kw.-hr., 380 kg. charcoal (70 per cent carbon), and 5 kg. of electrodes per metric ton of pig iron. When coke was used, the consumption was 2600 to 2700 kw.-hr., 310 to 320 kg. of coke, and 4 kg. of electrodes. The consumption of 2170 kw.-hr. with charcoal corresponds to 0.392 hp.-yr. at 85 per cent load factor. This is probably for the production of white iron from high-grade ores, though at the time of my visit ores of 50 per cent iron were being smelted. It does not appear that the efficiency is any better than that of the Electro-Metals furnace, and it should be noticed that the use of coke causes the consumption of a far greater amount of electrical power.

"The idea of this furnace is to increase the output and efficiency by using a far larger amount of power in a furnace of a given size than was possible in the Electro-Metals furnace. The furnace gases were not used to reduce the ore in the furnace, but were employed for other purposes in the plant. It is unfortunate that we have no detailed account of the operation of this furnace, or of the reasons which caused it to be abandoned."

The furnace itself is essentially a tall open-pit furnace with openings in the side walls somewhat below the top through which the gaseous products of smelting are sucked into a bustle pipe, to be transported elsewhere for use.

3. *The Noble Furnace.* After considerable experimentation between the years 1907 and 1911, one 2000- and one 3000-kw. furnace similar in form were evolved by the Noble Electric Steel Co., at Heroult, Cal. The latter was substantially a covered rectangular shaft 28 ft. long, 10 ft. wide, lined with firebrick, charged through vertical chutes 18 ft. high, in which the cold ore descended without heating. Between charging chutes the furnace was arched over; through these arches were four 12-in. graphite electrodes.

"The best account of this furnace was written by John Crawford, the plant manager, in METALLURGICAL & CHEMICAL ENGINEERING, July, 1913, Vol. XI, p. 383. The furnace gases are not used for preheating or reducing the ore, but are led away and used under limekilns and charcoal-retorts. The electric current is supplied to the furnace at a voltage of from 40 to 80. He found that coke was less satisfactory than charcoal in this furnace, but that if the coke was crushed a mixture of 60 per cent coke and 40 per cent charcoal could be used with fair efficiency. The following is an analysis of a 200-ton lot shipped to a foundry for making steel castings:

	Per Cent
Silicon	2.880
Combined carbon	0.098
Graphite carbon	3.300
Sulphur	0.028
Phosphorus	0.031

"Mr. Crawford does not consider this type of furnace as efficient as the shaft type, but states that he has kept the power-consumption as low as 2200 kw.-hr. per ton of pig in a furnace of 300 kw. This would equal 0.40 hp.-yr. at 85 per cent load factor. He states, however, that the long and narrow type offers the possibility of building several furnace units on to each other, like copper blast-furnaces, and this would lessen the radiation and electrical losses and increase the efficiency. It would also enable part of the furnace to be repaired while the remainder was still in operation."

4. *The Open Pit Furnace.* This type has been developed for calcium carbide and ferro-alloys; while it has never been used in the manufacture of iron, Beckman and Linden believe it is suitable for this duty. These men built and operated the furnace at Bay Point, Cal., for the Pacific Electro-Metals Co., illustrated and briefly described in CHEMICAL & METALLURGICAL ENGINEERING, Aug. 1, 1918, Vol. 19, p. 115. This furnace is a rectangular steel furnace, 17 ft. long, 9 ft. wide, and 7 ft. high, lined with 4½ in. of firebrick, and with a 3-ft. bottom of carbon butts. Three 24-in. carbon electrodes operate through the open top, spaced 3 ft. 6 in. centers, the lower ends being submerged in the granular furnace burden, which is shoveled constantly into the open top, heaping full. Current at 70 to 100 volts is used.

"There can be no question that charcoal pig iron of any desired grade can be made in this kind of furnace, which is easily and cheaply built and repaired, and should be able to run for a long time without need of repair. By providing an ample supply of power the efficiency should be satisfactory, and may be expected to approach fairly closely to that of the Swedish furnace. The charcoal-consumption will certainly be higher, but, as a poorer quality charcoal can be used, this need not cause any additional expense. The power-consumption will probably be higher; but it is impossible to speak

positively on this point, because the loss in heat, due to the open top and the absence of a stack, may be largely balanced by the greater efficiency of a higher-powered furnace, and by the fact that stoppages for repairs will be fewer and less prolonged. The consumption of electrodes will probably be larger per ton of pig iron, because they are somewhat exposed to the air, and perhaps also on account of the greater current density used in these electrodes. It is difficult to avoid the conclusion that, in operating such a furnace for the commercial production of pig iron, the management would ultimately be obliged to close in the furnace-top, so as to remove the gases from the furnace room. The furnace, so closed in, would then resemble the Helfenstein or the Noble furnace.

"If, then, it is decided to smelt in an electric furnace other than the Swedish type, it would be practicable to start with a simple pit furnace as used for ferromanganese."

Cost of Plant

Electro-Metals of London estimated the 1918 cost of a 6-furnace plant in Canada as $540,000, or $9 per ton of yearly output. These figures are based on a similar installation for Ansaldo in Italy. A plant for pig iron of half that size Dr. Stansfield estimates to cost $350,000 to $400,000, including land, wharf, trackage, and rolling stock, and when making gray pig of rather lower grade ore (53 per cent) would reduce 9000 tons per annum per furnace. This figures to approximately $15 per ton of yearly output.

"In order to obtain an independent judgment in regard to the general arrangement and cost of an electric-smelting plant in British Columbia, I discussed the design with Mr. R. H. Stewart of Vancouver, and he contributed some general considerations in regard to the design and cost data for the general portions of the plant, exclusive of the electrical furnaces and appliances.

"The design was for a plant of 20,000 hp. (15,000 kw.) for the production of 100 tons of iron daily and 20 tons of ferro-alloys. The plant was designed to handle daily the following quantities:

	Tons
Iron ore	200
Charcoal	50
Limestone	20
Electrodes	2
Manganese ore	20
Quartz	10
Chrome ore	10
Scrap-steel	20

"Although the plant as a whole was based on a daily capacity of 100 tons of iron and 20 tons of ferro-alloys, the electrical and furnace equipment is only about half of this, corresponding to a consumption of 10,000 hp., or 7500 kw., and a production of 50 tons of pig iron and 5 tons of ferro-alloys, provision being made for extension at a later date.

"The furnace building would be 50 ft. wide, 30 ft. high and 150 ft. long. It would contain along one long side two 3000-kw. open furnaces for smelting iron ore and three 300-kw. open furnaces for ferro-alloys. On the other side of this wall would be the transformer building, 30 ft. wide and 30 ft. high. The supplies of ore for the furnaces would be delivered by an elevated track in front of the furnaces and level with the charging-platforms. The furnace gases would be removed by flues below the charging platform. The pig iron could be tapped into large ladles and cast in sand or in a casting-machine or poured direct into a bessemer converter for steel-making. The ores and other supplies coming by water would be unloaded into storage by a locomotive crane. The charcoal would need a large storage shed, perhaps 300 ft. long and 90 ft. wide, which would contain a month's supply, stored not more than 10 ft. deep.

"The order of operations would be as follows:—

(1.) Unloading from the dock directly into storage.
(2.) Removal from storage, using the same crane, to crushing and sampling plant.
(3.) Removal from crushing plant to the furnace charge-bins.
(4.) Delivering from charge-bins over weighing-hoppers to the charge-cars and thence to the side of the furnace.
(5.) Smelting for pig iron or ferro-alloy.
(6.) Molten pig iron received in ladle and handled by crane to casting-bed or casting-machine or to steel-making furnace.
(7.) The slag would be received in a ladle and removed by a locomotive.

"The following is based on Mr. Stewart's estimate for the cost of buildings and general plant. Items for the [open pit] furnaces and electrical equipment have been added from Beckman and Linden's estimate:

20,000-HP. PLANT WITH 7000 KW. OF ELECTRIC FURNACES AND EQUIPMENT

Mr. Stewart's items:	
Locomotive crane, buckets and grab-buckets	$19,000
Dock, say	10,000
Electric locomotive, cars and equipment for handling between the wharf and the crushing plant	10,000
Crushing and sampling, say	17,000
Charcoal storage for one month's supply	8,000
Tracks, etc., for the above-mentioned equipment	3,500
Lifting-magnet for steel scrap, etc	1,200
Storage of manganese ore	3,500
Storehouse for electrodes and other supplies, including a small crane	6,000
Six furnace charging-bins, including weighing-hoppers and mechanical feeders	9,000
Tracks, charge-cars, and locomotive, with supports for the overhead track	10,000
Furnace building, including crane runway	25,000
Transformer building	12,000
3- to 10-ton ladles	6,000
Flues and stacks	25,000
20-ton crane, 50-ft. span	18,000
Laboratory and equipment	6,000
Office	5,000
Machine-shop and blacksmith's shop	12,000
Wash-house and change-room	3,000
Slag-handling equipment	8,000
Items from Messrs. Beckman and Linden:	
Two 3000-kw. 3-phase furnaces, installed	30,000
Seven 1000-kw. single-phase transformers	45,500
Two sets low-tension buses for 3000-kw. furnaces	10,000
Two sets high-tension buses, etc., for 3000-kw. furnaces	12,000
Three 300-kw. single-phase furnaces, installed	10,000
Four 300-kw. transformers, installed	10,000
Three 50-kw. single-phase transformers	2,000
One 25-kw. motor-generator set for regulators	2,000
Three sets low-tension buses for 300-kw. furnaces	1,500
Land, say	6,000
Engineering and contingencies, 20 per cent on $129,000	25,800
Total	$372,000

"Modifying this estimate to represent a plant of 9000 kw. making pig iron only, we have:

9,000-KW. PLANT FOR PIG IRON

Mr. Stewart's items	$217,000
Three 3000-kw. furnaces	45,000
Eleven 1000-kw. transformers	71,000
Three sets low-tension buses	15,000
Three sets high-tension buses, etc	18,000
Three 100-kw. transformers	3,000
One 25-kw. motor-generator	2,000
Land	6,000
Engineering, etc., 20 per cent on $160,000	32,000
Total	$409,000

"These figures agree with the previous estimate of $400,000."

Cost of Making Pig Iron in Swedish Furnace

Table IV contains available and estimated costs by Swedish practice. Costs from Electro-Metals are for a large plant, and show what can be done under exceptionally favorable conditions. Mr. Leffler's figures appeared in *Iron Age*, Sept. 13, 1917, p. 605. The increased amount in Stansfield's estimate is due in about equal proportions to the increased charges for ore power and labor. Items in Dr. Stansfield's estimates are

explained in previous sections, and interest is taken on $400,000 for plant plus $100,000 working capital, while 10 per cent depreciation (somewhat moderate) is figured on the plant.

Conversion of White Iron Into Foundry Pig

"On account of the fact that the Swedish furnace is generally used for the production of a white pig iron containing not more than about 1 per cent of silicon, we have no exact data for the production of foundry iron of, say, 3 per cent of silicon in this furnace. We are satisfied, however, that there would be a decided increase on this account in the cost for power, charcoal, electrodes and maintenance, besides the general overhead, labor and interest charges. In view of this, it is worth while to consider what the cost would be of converting white iron into foundry iron by the addition of ferrosilicon. One ton of iron containing 1 per cent of silicon would need the addition of 0.04 ton of 50 per cent ferrosilicon to raise its silicon content to 3 per cent. This ferrosilicon would cost, made in the plant, about $85 per ton, or $3.50 for the amount needed.

"If the pig iron were received in a large ladle and the ferro were thrown in red hot, there should be enough heat to effect a perfect mixture; and as the iron is cast into pigs for sale, and then remelted in a cupola, any irregularity would be remedied before the final casting. The saving in the cost of smelting through producing white iron instead of foundry iron would about equal the cost of the ferrosilicon, and there would be the added advantage of making a single furnace product and turning as much of this as was needed into foundry iron.

Difference in Cost

"Mr. Gronwall, in his estimate in 1914, places the difference in cost between gray and white pig iron as:

0.03 ton of charcoal.
0.03 horsepower-year.
5 lb. of electrodes.
10 cents for repairs.
7 cents for petty charges.

"Under our conditions this would mean:

Charcoal at $8	$0.24
Power at $15	.45
Electrodes at 8 cents	.40
Repairs and petty charges	.21
Total	$1.30

"We must add, however, a proportion of the charges for labor, management, and fixed charges amounting to about 60c., thus bringing the whole up to $1.90. The additional expense may easily be as much as 0.05 ton of charcoal and 0.05 hp.-yr., and the increased cost would then be about $3 a ton (everything considered), or nearly as much as the cost of the ferrosilicon addition.

"The ferrosilicon used was found to cost $3.50, but, as it replaces an equal weight of pig iron costing $1, the net cost of the addition will only be $2.50 per ton of the resulting foundry iron.

"The foregoing discussion is not intended to prove that the addition of ferrosilicon to white iron is the best way of making foundry iron, but merely that the use of the Swedish furnace for foundry iron would be perfectly safe, because ferrosilicon could be added without much additional expense if it were found impracticable to make foundry iron directly."

Cost of Smelting in Pit Furnace

Dr. Stansfield conservatively assumes the following power and charcoal used per long ton of iron in a pit furnace:

	Hp.-Yr.	Net Ton Charcoal
White iron from 65 per cent concentrate	0.35	0.45
White iron from 50 per cent ore	0.43	0.45
Gray iron from 65 per cent concentrate	0.42	0.50
Gray iron from 50 per cent ore	0.50	0.50

On such a basis the cost of making one long ton of foundry pig in pit furnaces (10,000-kw. plant) is as shown in Table V.

TABLE V. COST OF IRON FROM PIT FURNACE

	From 55 per Cent Ore			From 65 per Cent Concentrate		
	Quantity	Price	Amount	Quantity	Price	Amount
Iron ore	2 tons	$4.00	$8.00	1.43 tons	$6.97	$10.30
Electrical power	0.5 hp.-yr.	15.00	7.50	0.42 hp.-yr.	15.00	6.30
Charcoal	0.5 ton	6.00	3.00	0.5 ton	6.00	3.00
Electrodes	20 lb.	.10	2.00	20 lb.	.10	2.00
Flux	.....	.....	?	.....	.....	.....
Labor	.....	.....	6.00	.....	.....	6.40
Supplies	.....	.....	1.00	.....	.....	1.00
Plant and general office expenses	.....	.....	3.00	.....	.....	5.00
Interest and depreciation	20% on $120,000		3.00	20% on $140,000		2.81
Total	.....		$33.50	Total	.....	$36.81

In all the above estimates it should be carefully noted that electric energy was assumed to cost $15 per hp.-yr., the understanding which the author held until shortly before his report was written, as already noted above in the section on "Cost of Electric Power for Smelting." Charges of ½c. per kw.-hr. quoted him later are so high as to render impossible any large-scale production of electric pig iron in the Swedish or open-pit furnace.

Comparison With Blast-Furnace Methods

"It may be of value to compare with my estimate of the cost of making pig iron in the Swedish furnace the following estimates by the B. L. Thane Co. of the cost

TABLE IV. COST WITH SWEDISH FURNACES

	European Plant by Electro-Metals		North Sweden by J. A. Leffler		British Columbian 1918 by A. Stansfield		British Columbian Minimum by A. Stansfield	
Capacity per annum	60,000 tons white iron		?		27,000 tons gray iron		27,000 tons gray iron

of making pig iron in a large blast-furnace near Puget Sound at 1918 prices:

B. L. THANE COMPANY'S ESTIMATE OF THE COST PER LONG TON OF BLAST-FURNACE PIG IRON

Iron ore, 3,457 lb. at $4.40 per long ton	$6.81
Coke, 2,485 lb. at $9.60 per net ton	11.93
Limestone, 1,000 lb at $1.90 per long ton	.81
Labor	1.50
Materials	1.50
Capital charges	3.40
Total	$25.95

"There does not appear to be any cause, other than the different size of the furnaces, why electric-furnace iron should cost more than blast-furnace iron under the conditions we find on the Coast, and providing that power can be obtained at $15 or less.

Auxiliary Industries

"In view of the limited market for foundry pig iron in British Columbia, it will be essential to make other products, so as to increase the output of the plant. For this purpose an additional output of low-silicon pig iron can be made, and this can be melted with steel scrap for the production of steel. Ferro-alloys, such as ferro-silicon, ferromanganese and ferrochrome, can also be made in an electric-smelting plant. These auxiliary industries not only increase the general output of the plant, thus reducing, proportionately, the overhead charges, but are themselves likely to yield a higher profit than the production of pig iron."

Attached is Table VI giving the itemized cost of various ferros.

On the basis of power at 0.5c. per kw.-hr., 80 per cent ferromanganese would cost $136.15 per ton. In 1913 this alloy sold in the Eastern States at $50 per long ton. [On April 15, 1919, this journal quoted $130 to $150 per long ton.]

A small furnace making silicomanganese with 0.5c. per kw.-hr. power would cost about $110 per ton. [Silicomanganese is not in general use among American steel plants.]

On the basis of power at 0.5c. per kw.-hr., 65 per cent ferrochromium would cost $194.40 per ton. [Such ferro-chromium was quoted in this journal on April 15, 1919, at from $416 to $520 per short ton.]

On the basis of power at 0.5c. per kw.-hr., 50 per cent ferrosilicon would cost $81 per ton. In 1913 this alloy sold at $73 per ton. In October, 1918, it is quoted at $160 per ton, and on April 15, 1919, it was from $90 to $150 per gross ton.

"In order to be able to make pig iron on as large a scale as possible, and also with a view to combining more profitable industries with that of iron-smelting, it is desirable to introduce into the electric-smelting plant furnaces and other appliances for making steel. The general scheme suggested is that about 25 tons of foundry iron should be produced daily for sale to iron-foundries, and a further 25 or 30 tons of white pig iron should be made for conversion into steel in the same plant or elsewhere. The steel would probably be made in small open-hearth furnaces heated by oil, or in electric furnaces of the Heroult type. Together with 30 tons of pig iron, about 60 tons of steel scrap could be used if desirable, thus yielding about 85 tons of steel daily. This could be used in part for making steel castings, and the remainder could be rolled into rods and bars of small section in a small rolling-mill. I may add the following estimate, made by Lyon & Keeney in 1915, for the cost of electric steel-making in the Western States (*Trans.*, Amer. Electrochem. Soc., 1915, XXVII., page 158):

COST OF PRODUCTION OF ONE LONG TON OF STEEL IN THE ELECTRIC FURNACE IN THE WESTERN STATES

1.1 tons of scrap at $15 per ton	$16.50
Slag materials	1.00
Ferro-alloys	1.00
800 kw.-hr. at 0.20c.	1.60
Labor	2.50
Maintenance and repairs	2.40
20 lb. of electrodes at 5c.	1.00
Amortization and depreciation at 5 per cent each	1.50
Interest at 6 per cent	.90
General	1.00
Royalty	.50
Total	$29.90

"The present cost of making steel in British Columbia will be considerably higher than this estimate, on account of the higher cost of supplies and operation."

Edgewood Arsenal Has New Commanding Officer

Edgewood Arsenal, which is the Gas Offensive Division of the Chemical Warfare Service, U. S. A., has now come under the command of Lieut.-Col. Amos A. Fries, Corps of Engineers, (C. W. S.), U. S. A., who as Brigadier-General, National Army, A. E. F., commanded the C. W. S. forces throughout the war in France.

Col. William H. Walker, formerly of the Massachusetts Institute of Technology, Boston, who has been the commanding officer of Edgewood Arsenal, has been honored with a Distinguished Service Medal by the Secretary of War and is now returning to pursue his profession in civil life.

Edgewood Arsenal, with its headquarters at 311 West Monument St., Baltimore, has arsenals located at Edgewood, Md.; Hastings-on-Hudson, N. Y.; Kingsport, Tenn.; Midland, Mich., and South Charleston, W. Va. The arsenals formerly located at Stamford, Conn.; Bound Brook, N. J.; Niagara Falls, N. Y., and Buffalo, N. Y., have been sold.

Decision on Frasch Patents on Sulphur Mining

By Hugo Mock and Asher Blum

THE Circuit Court of Appeals of the Third Circuit, which is a Federal Appellate Court having jurisdiction over the States of Pennsylvania, Delaware and New Jersey, rendered the following decision in March which, as the Court states, "involves basic matters affecting the whole sulphur product of the United States."

A proper comprehension of this extremely important decision, which enables the Freeport Texas Co. and other concerns owning sulphur beds similar to the enormous deposit found in Louisana to compete with the Union Sulphur Co., requires a brief historical survey of sulphur mining as originated and practiced in America.

Prior to the development of sulphur mining in America, nine-tenths of the world's supply was produced in Sicily by extremely primitive methods which involved shafting and other ordinary methods used in mining. In 1869 an enormous deposit of sulphur was discovered in Louisana when a well was being drilled for oil. All efforts to mine this proved unsuccessful for twenty-five years until Herman Frasch took up the problem.

Court Eulogizes Mr. Frasch

The Court pays a handsome tribute to Mr. Frasch, who, it states, "in inventive fertility and past experience seemed to be the one man to solve the difficulty and successfully work out one of the most remarkable wonders of world commerce."

Mr. Frasch resolved to give up the mining methods and shafting which had proved ineffectual because of the presence of quicksand and water and because of the presence of sulphurous gases which had killed several men. Mr. Frasch was very experienced in oil well work and his "daring, original and inventive step" consisted in forcing hot water into the sulphur bed so as to melt the sulphur, and then pumping up the molten sulphur to the surface and separating it from the water.

In 1890, Mr. Frasch filed applications in the United States Patent Office which resulted in the grant of U. S. Patent No. 461,429 for a process of mining sulphur, and Patent No. 461,430, which covered apparatus for mining sulphur, and these patents were issued on Oct. 20, 1891, so that by operation of law they would expire on Oct. 20, 1908, and then become free, public property. A third patent, No. 461,361, also issued on the same day, but it played no importance in the decision.

The First Frasch Patent

In the U. S. Patent No. 461,429 Mr. Frasch stated that his method was useful for sulphur deposits which were overlaid with beds of quicksand which therefore prevented shafting. The method disclosed in this patent required that an ordinary well should be drilled through the limestone above the sulphur, a casing being forced through this limestone and through the quicksand by the ordinary methods used in drilling oil wells and the like. This shut off water and the quicksand. When the casing reached the sulphur, a hole of smaller diameter was continued to the bottom of the sulphur deposit. Tubing of smaller diameter than the casing was then passed through the casing and the hole in the sulphur in a central position, and this tubing was passed above the ground to a casing head. Water at about 270 to 280 deg. Fahrenheit was then forced down by a pump between the tubing and the casing to the bottom of the hole in the sulphur, where it melted the sulphur and forced it up through the tubing to proper separators.

U. S. Patent No. 461,430 also showed a pump at the bottom of the tubing which could be used to raise the molten sulphur. Thus the mine could be filled with hot water to melt the sulphur and the sulphur could be periodically removed by this pump. A modification of this apparatus showed a bleed pipe extending from the surface of the ground to the hole in the mine, the bottom of the bleed being higher than the bottom of the casing and tubing. This bleed pipe could be used to draw off the hot water while the sulphur was pumped up by the pump before mentioned.

Frasch's first well was drilled in the fall of 1894 and was worked for four or five hours, producing about 500 bbl. of sulphur, when mechanical difficulties due to the sulphur corroding the iron-working parts of the valve and pump, and the weakness of the boiler used to supply the hot water, caused the stoppage of operations.

Why Complete Commercial Success Was Delayed

Various reasons delayed complete commercial success until 1903, but the Court stated, "We are satisfied that such delay and difficulties were not caused by defects in Frasch's original conception or in means to utilize it. As already pointed out, Frasch was immersed in other work; he regarded this as a side issue; his visits were infrequent; the work was frequently suspended, for as much as a year at a time; the finances were such that the work was badly hampered."

In the meantime, and before commercial success had been secured, Frasch filed another application, on May 27, 1897, which resulted in the issuance of two patents on Sept. 19, 1905, 799,642 and 800,127. In addition, Frasch was also granted U. S. Patent No. 1,008,319 on Nov. 14, 1911.

In U. S. Patent No. 799,642, Frasch stated that his earlier patents were unsatisfactory because since the sulphur had been found to be porous he could not develop sufficient pressure with the water pump to raise the column of molten sulphur and that a lifting pump gave trouble with its valves. In addition, the water with which the deposit of sulphur was saturated cooled the incoming hot water so that the yield of sulphur was small. The novelty in this patent consisted in not returning the water to the surface, but forcing it out through the porous rock so as to heat it even when the temperature of the water was below the melting point of sulphur. The water was now forced in at about 300 deg. Fahrenheit to counteract the effect of the cold water in the porous deposit.

Frasch's Later Patent

The apparatus shown in this patent showed a pipe corresponding to the casing of the earlier patents, which was driven down to the rock. An inner and centrally located hot water pipe was then passed through the casing to the bottom of the sulphur. This hot water pipe had a plug at its bottom and was perforated above the plug so as to allow the hot water to escape into the mine. A sulphur-raising pipe of less diameter than the hot water pipe was centrally located therein and was connected with the plug of the hot water pipe. The bottom of the sulphur-raising pipe was provided with a strainer and had an air-injecting pipe located

therein which was provided with a perforated bottom piece. Of course all these pipes extended to the surface of the ground. The bottom of the casing, or mine pipe as it is called, was higher than the bottom of the hot water pipe. Hot water was forced into the mine pipe and also into the hot water pipe, so as to fill them to a certain height. The hot water issuing from the mining pipe melted the sulphur and caused it collect around the bottom of the hot water pipe and the sulphur-raising and air-injecting pipes so as to seal them, while the water from the hot water pipe flowed directly over the molten sulphur and kept it hot. The hot water was allowed to flow away through the surrounding porous rock. Air was injected from the air pipe until the density of the sulphur was lowered to about that of water so that it could be easily raised by the column of water in the hot water pipe.

U. S. Patent No. 800,127 had about the same disclosure as No. 799,642, and mentioned that no provision was made for the return of the hot water which was forced out through the walls of the cavity in the sulphur and into the walls of the surrounding rock. U. S. Patent No. 1,008,319 covered the idea of injecting the hot water into the mine through a strainer so as to divide the stream of hot water over a wider zone and prevent clogging.

Union Sulphur Co's Claims

The Union Sulphur Co., which had acquired these three later patents, sued upon claims 2, 3, 6, 12, 19, 21 and 22 of No. 799,642, upon claims 2, 3, 7, 11, 21 and 24 of No. 800,127, and upon claims 7, 20 and 28 of No. 1,008,319.

The claims of No. 799,642 attempted to cover particularly the following points:

1. The forcing of water heated above the temperature at which melted sulphur begins to darken into the deposit and out through the surrounding rock, and removing the melted sulphur.

2. The use of injected air to lessen the density of the sulphur.

3. The injection of hot water into the cavity in the sulphur at two different levels, that is, one from the casing or mine pipe and another from the hot water pipe.

The claims of No. 800,127 in issue attempted to cover the apparatus for carrying out the above-mentioned process. The three claims of No. 1,008,319 attempted to cover the point already defined, namely, spraying out the hot water through a strainer.

Importance of the Litigation

The great importance of the litigation consisted in the fact that the porous character of the sulphur deposit made sulphur mining in America impractical unless the process and mechanism disclosed in the later patents and covered by these claims were used, so that if these claims would have been sustained the Union Sulphur Co. would have had a monopoly at least up to Sept. 19, 1922, when its patents No. 799,642 and No. 800,127 would expire.

The Union Sulphur Co. contended that when Frasch commenced his operations and applied for his patents issued in 1891 he was absolutely ignorant of the porous character of the Louisana sulphur deposit and that he believed that it was impervious to water, which was alleged to be the case in the Sicilian sulphur deposits, and that the earlier Frasch patents were valueless and impracticable, while the later Frasch patents involved an advance over them of great practical merit.

The Freeport Texas Co. contended that Frasch well knew from the very inception of his operations that the Louisiana deposit was porous and that the later Frasch patents represented nothing novel or patentable over his earlier patents, but were merely an attempt to stretch out the monopoly of the Union Sulphur Co. so that it would have the control of the American sulphur market from 1908 to 1922, and it pointed out that while Frasch had filed his second series of patents in 1897 the actual issuance of these patents had been delayed until 1905.

The Court's Decision

The Court very carefully analyzed all the testimony in a decision covering eighteen printed pages, and it came to the conclusion that since Frasch had examined a sample of the Louisana sulphur and from other circumstances he was well acquainted with the porous character of the Louisana deposit from the commencement of his work and that there was no basis for any patentable novelty in the later patents. The Court held that it involved no invention to apply the hot water at two different levels instead of at one, as was done in the first Frasch patents, or to use air pressure as a means of bringing the liquefied sulphur to the surface, and that Frasch's former patents were not restricted to a tight and non-porous rock. The Court also held that to distribute the hot water through a perforated lining was a common mechanical expedient and involved no invention. Accordingly, it ordered the complaint of the Union Sulphur Co. to be dismissed.

Does Not Bar Other Suits Elsewhere

This decision does not prevent the Union Sulphur Co. from bringing a like suit against some other company which may be located outside of the States of Pennsylvania, Delaware and New Jersey, and while the Federal Courts outside of the Third Circuit would feel inclined to follow the decision of this Circuit Court of Appeals, they are not bound to do so, and since a number of cases have arisen where the Circuit Courts of Appeals of different circuits have disagreed in their decisions upon the same patents, there is a possibility of the patents being sustained in some other of the nine judicial circuits into which the country is divided. The Supreme Court may still exercise its discretion to review the decision of the Circuit Court of Appeals of the Third Circuit and this will almost certainly follow as a matter of course if some other Circuit Court of Appeals disagrees with the Circuit Court of Appeals of the Third Circuit, as in such event the Supreme Court finally passes upon the case, so as to cause uniformity of authority throughout the entire country.

New York, N. Y.

Removal of Tin Import Restrictions

Applications for licenses to import tin ore and tin concentrates will be considered by the War Trade Board. These licenses will permit the importation of shipments made from points of origin on or after June 8, 1919, and will not be valid for entry until July 1.

Civil Service Examination.—Applications will be received until July 1 for the position of superintendent of heat treatment. There is a vacancy in the U. S. Naval Ordnance Plant, South Charleston, W. Va., at $5000 a year.

Kingsport, Tennessee, and Its Chemical Industries—II

A Brief Historical Survey of a Progressive Young American City, With a Technical Description of Its Varied Chemical Plants and Their Processes—Coal-Tar Dyestuffs and Intermediates—Tannery and Tanning Extract Plant—Wood Pulp

THE plant now owned and controlled by the Union Dye & Chemical Corporation was built by the Federal Dyestuff & Chemical Co. in 1915-16. Operations were begun in 1916, and after a brief career, the Federal Co. went into the hands of a receiver in 1918. On Aug. 15, the same year, the plant was sold by the receiver to the Union Dye & Chemical Corporation, Chester A. Jayne, president, J. F. White, general manager, and J. J. Bajda, technical director. The company is capitalized for $3,000,000 and has offices at 2 Rector St., New York, N. Y.

The new company is not only manufacturing the products of its predecessor, but is planning and preparing to greatly expand its scope, and to place on the market a line of chemicals, dyestuffs and intermediates far more extensive than the limited variety produced by the former owners of the plant. Buildings and equipment are being overhauled and remodeled, and new machinery is being installed, preparatory to instituting substantial economies in operating methods, and to producing the best grade of goods at lowest possible cost.

The principal colors now being manufactured are sulphur black, sulphur blue, sulphur red, sulphur brown, sulphur green, sulphur yellow and sulphur maroon. Other chemicals now being produced for sale are: Aniline and its derivatives, ortho- and para-toluidine, azo colors, intermediates, caustic soda, monochlorbenzol, bleaching powder, hydrochloric acid, nitric acid, and alizarine dyes.

It should be understood that on account of the keen competition in the dye industry, it is impossible to publish very many of the details of equipment or of processes in this plant. As some of these processes have been worked out after much painstaking and expensive research work, necessarily the nature of the materials used and of the chemical reactions involved in the dye-making processes cannot be fully disclosed.

All power used at this plant, as at all the industrial plants of Kingsport, is obtained from the Kingsport Utilities Corporation. No interruptions to this power are experienced, but in case for any reason this power should fail, the dye company could generate its own power. The company has two air compressors, and is now installing an ice plant, the manufactured ice and the cold circulating brine to be used in its chemical processes. The boiler house is equipped with two Henry Vogt Machine Co. boilers, 300 hp. each, and these furnish steam for heating and drying purposes.

Sulphur Black and Sulphur Blue

Sulphur black is made in the dinitrochlorbenzol nitrating building. Monochlorbenzol is treated with a mixture of nitric and sulphuric acids of high concentration in nitrators (of which three have been installed), heated with steam coils. The product of this treatment is dinitrochlorbenzol. This is blown into fusion kettles, and from there to oxidizing kettles, where it undergoes further treatment, and is then filter-pressed and dried by vacuum and steam. The product, known as crude sulphur black, is sent to the standardization department, and here it is analyzed and brought to standard strength. This dye, known as standard sulphur black, is then packed in strong wooden barrels, containing about 500 lb. each, for shipment. It is used for dyeing cotton or wool, but not for silk.

The process for the manufacture of sulphur blue is practically a duplication of the sulphur black process, with, of course, the necessary substitution of chemicals. The starting point for sulphur blue is indophenol. This is blown first into fusion kettles, then into oxidizing kettles, where it is oxidized, and is then filter-pressed. From the filters, the crude sulphur blue is sent to the drying room, where it is placed on trays, which are arranged on shelves in the hot air cupboard, and subjected to a blast of hot air, which passes over and under the shelves. The dried dye is then sent to the standardizing department, where it is standardized, and is then placed in ball mixers (revolving steel drums containing iron balls), where the dye is crushed to powder. Sulphur blue is used for dyeing cotton, wool and silk. The capacity for the manufacture of sulphur blue or black is practically unlimited, the output being determined by the demand.

Nitrobenzol and Nitrosophenol

Nitrobenzol is manufactured by the usual process of mixing benzol with a mixture of nitric and sulphuric acids of high concentration. The acid mixture consists of 29 per cent HNO_3, 61 per cent H_2SO_4, and 10 per cent water. The chemicals are heated in steam jacketed nitrators, each provided with an agitator, manufactured by the Buffalo Foundry & Machine Co. There are four of these nitrators, each 10 ft. high by 6.5 ft. in diameter. The reaction takes place at 140 to 150 deg. C. When the reaction is completed, the nitrobenzol is blown to the nitrobenzol wash-house. Here the nitrobenzol is washed four times in a wooden vat provided with an agitator. The washed nitrobenzol is then drawn off into a blow-case, and blown to the aniline plant, where it is received in twelve feed tanks, supplying twelve reducers. The latter are steel cylinders on end, 10 ft. high by 8 ft. in diameter, each heated by a steam coil and provided with an agitator. The nitrobenzol is fed into the reducer, along with iron borings screened to 40-mesh size. Heat is applied and the reaction starts immediately. The mixture is agitated continuously for from 24 to 36 hours. As the reaction proceeds, the temperature is gradually increased, and the aniline vapors pass off through a 6-in. pipe to condensers, which are steel cylinders, 25 ft. high by 6 ft. in diameter. Here the vapors are condensed, and the liquid is collected in receiving flasks.

Nitrosophenol is manufactured as follows: Phenol and caustic soda are mixed in one tank, and water,

UNION DYE AND CHEMICAL CORPORATION

sodium nitrite and sulphuric acid in another. The two liquid mixtures are then agitated together in a tank provided with a mechanical stirrer revolving at the rate of 38 r.p.m. The product, nitrosophenol, is filtered, then centrifuged. The time required for the manufacture is about six hours. Nitrosophenol must be handled in containers made of steel or other non-combustible material. Indophenol is made by combining nitrosophenol, sulphuric acid and orthotoluidine in condensation tanks equipped with agitators and brine coils. When the reaction is completed the indophenol is allowed to flow into tanks, where it is precipitated by means of sodium carbonate. After precipitation is completed, the indophenol (an intermediate used in the manufacture of sulphur blue) is filter-pressed. After filtering, the indophenol still carries about 50 per cent of moisture. It is placed in buggies and used in the sulphur blue department. The total time required for the manufacture of indophenol is eight hours.

Chlorine for making the monochlorbenzol used in the manufacture of sulphur black is made in the electrolytic cell house. A solution of common salt is electrolyzed in the Allen-Moore cell, manufactured by the Electron Chemical Co., 347 Madison Ave., New York City. There are three series of cells, 136 cells to a series, or 408 cells in all. Caustic soda is made here as a by-product. The caustic solution goes to evaporators, where it is concentrated to a strength of 30 per cent. The strong solution is then pumped to cooling tanks, cooled, and the salt settled out. The caustic solution then passes to storage tanks, and thence to the finishing department, where the caustic is brought to the solid state, and packed in drums for shipment.

In the still house, containing three stills, liquid residues from the various manufacturing operations go through a fractionating process for the recovery of benzol, monochlorbenzol and dichlorbenzol.

In the chlorination house benzol and chlorine come into contact with each other in counter current, in Lummus chlorination columns, of which there are six. The product, monochlorbenzol (used in the manufacture of sulphur black) is pumped to a washer and washed, and is then pumped to storage tanks for use as needed. The exit gas escaping from the top of the chlorination columns goes through a cooler, then to the hydrochloric acid house. The latter contains three towers, arranged in series, built of acid-proof stoneware furnished by the United States Stoneware Co. of Akron, Ohio, and packed with acid-proof brick and 6-in. spiral rings. The liquid flows from tower to tower in a direction opposite to that taken by the gas. The liquid is elevated to the tops of the towers by pulsometers made of chemical stoneware (likewise furnished by the United States Stoneware Co.), through 1-in. glass tubes. All of the hydrochloric acid manufactured is placed on the market.

Nitric Acid Department

In the nitric acid department there are four retorts now operating, and four more will soon be installed. The retorts, manufactured by the Pratt Engineering Company of Atlanta, Ga., take a charge of 7000 lb. of nitrate of soda each. Sulphuric acid 66 deg. B., recovered from the spent acids used in other manufacturing processes, is added to the retorts, and the mixture distilled. The fumes are condensed in S-shaped Duriron pipes sprayed with water, and the gases uncondensed there go through a series of five chemical stoneware towers, the five towers serving as a common condensing system for the four retorts. The last tower of the series is fed with water, and the liquid then goes from tower to tower in a direction opposite to that taken by the gas. As in the hydrochloric acid plant, the liquid is pumped to the tops of the towers by means of chemical stoneware pulsometers through 1-in. glass tubes.

The nitric acid condensed in the S-condensers, after passing through Duriron bleachers, is received in Duriron flasks. Two grades of nitric acid are made—a strong acid, made in the condensers, and a weak one, made in the towers. The strong grade is used in the sulphur black process, where only 4 per cent of water is allowable in the acid mixture; while the weaker grade is used for the manufacture of nitrobenzol, where the water in the acid mixture may be as high as 10 per cent.

To make the mixed acid used in the dye-making processes, the nitric acid is pumped into a steel mixer equipped with an agitator, and is there mixed with oleum, which is purchased from the General Chemical Co., of Pulaski, Va.

The spent acid recovery plant is for the recovery of sulphuric acid from the spent acids used in other manu-

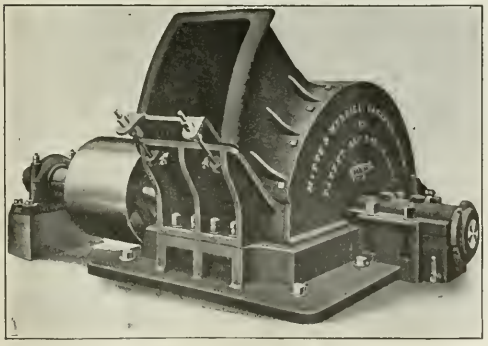
facturing processes. The spent acid is fed into a tower made of acid-proof brick, and packed with chemical brick and 6-in. spiral rings, up which pass the combustion gases from the furnaces used to heat two benches of pan concentrators. The acid discharged from the tower divides, and goes to both of these two benches, each of which consists of three cast-iron pans arranged in cascade and in series. The 66 deg. acid flows from the lowest pan of each series into a cooler, and this is sent to the nitric acid department to be used in the manufacture of nitric acid.

Tannery and Tanning Extract Plant

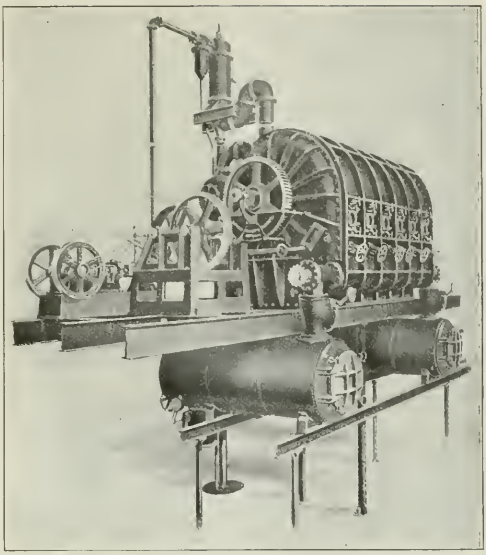
The latest industrial development of Kingsport is the Lang-Grant Leather Corporation, recently organized by the Simmons Hardware Co. of St. Louis, Mo. On the first day of April, this year, this recently organized company took over the control of the plants of the Kingsport Extract Corporation and of the Kingsport Tannery, Inc., both recently purchased for the purpose of consolidation with a new plant, already under construction, for the manufacture of finished leather goods, such as harness, saddles, horse collars and gloves. The existing plants will be described briefly first, and then the plans of the new organization for the future will be discussed.

The Kingsport Extract Corporation manufactures tanning extract from chestnut wood, oak bark and hemlock bark, all of which abound in the vicinity. From these raw materials, three different kinds of extract are made, chestnut, oak and hemlock. The first step in the manufacture of tanning extract is to shred, or chip, the wood, and grind the bark. The bark is put through a bark mill, and the ground bark is then delivered to the leaching vats. The chestnut wood is put through a chipper, commonly called by the extract men a "hog," manufactured by Mitts & Merrill, Saginaw, Mich. From the chipper the wood goes to a shredder, made by the Jeffrey Manufacturing Co., Columbus, Ohio. The wood, as discharged from the Jeffrey shredder, is not in the most desirable condition for conversion into paper pulp, and since the erection of the neighboring pulp mill, which now utilizes a large proportion of the spent chestnut chips of the extract company, the wood destined to reach the pulp mill is chipped by passing it through a Carthage disc chipper, made by the Carthage Machine Co., Carthage, N. Y.

In whatever way the wood may be comminuted, the chips are delivered to the vats and treated with water



WOOD CHIPPER



VACUUM DRUM DRIER

and steam. There are three sets of vats, eight vats to a set, each vat 14 ft. in diameter by 15 ft. high. Of the eight vats in a set, one will be loading chips, one discharging spent chips, and six in service. The solution is pumped in series from one vat to the next in the set, a fresh supply of water being introduced in the vat containing the chips which are most nearly spent, and the strongest liquor going to the vat containing a new batch of chips. Thus, as the liquor proceeds from vat to vat, it comes in contact with chips containing more and more undissolved tannin, and so the solution becomes stronger and stronger. Steam is introduced into one vat only—the first, containing the fresh supply of water and the nearly spent chips.

After coming in contact with a new batch of chips, the strong solution is withdrawn, and is then evaporated under 14 in. vacuum in copper evaporating pans heated by copper steam coils manufactured by Jos. Oat & Sons, Philadelphia, Pa. The evaporation here is carried to 65 deg. as indicated by the barkometer. There are four of these evaporators, three large and one small.

The concentrated solution obtained from these evaporators is further evaporated to a powder in the vacuum drum drier, manufactured by the Buffalo Foundry & Machine Co.

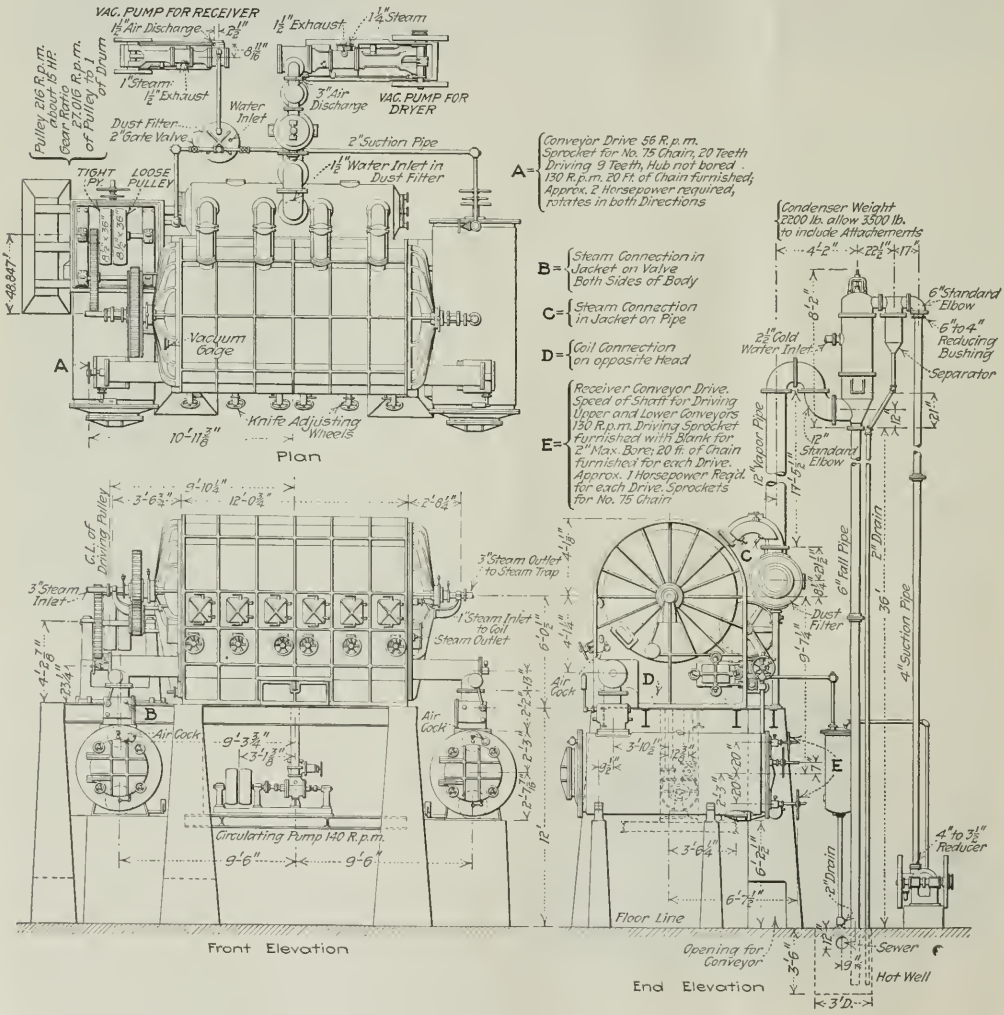
The high content of wood sap sugars in the concentrated extract makes drying without caramelizing impossible in bulk boiling processes. After the extract has been evaporated in bulk to a point where solids are tending to form on the heating walls of the concentrator, the liquor is pumped to the vacuum drum drier reservoir. From here it is circulated through the drum coating pan in such a way that all foam is removed and a homogeneous layer of extract syrup applied to the rotating steam heated drum. The speed of the drum is so adjusted that a layer of dried extract is obtained at the scrapers and dropped into the conveyor. Twenty-eight inches of vacuum gives the necessary low boiling temperature and there is no possibility of burning or oxi-

dizing the extract. The flaked extract goes by a conveyor belt from the drum drier to the shipping room, where it is packed in bags. It will be appreciated that a very important saving is made in shipping costs as compared with the old barreled liquor method. The capacity of the extract plant is 45,000 lb. per day.

Kingsport Tannery, Inc.

A natural adjunct to a tanning extract plant is a tannery, and the Kingsport Tannery, Inc., has for some time been operated under the same management as the Kingsport Extract Corporation. Every tannery uses its own blend of tanning extracts. The blend adopted by the Kingsport Tannery consists of 80 per cent chestnut and 20 per cent oak.

The raw hides as received from the slaughter houses are folded and tied up in bundles about 16 in. square. They are unfolded, and soaked in water for two days to eliminate dirt and blood. They are then placed in vats, where they are treated with a solution of lime for five days, during that time being reeled over from one vat to another, getting a little stronger solution of lime each day. They are then put into warm water, and depilated. After that the hides are "fleshed," i.e. all adhering bits of flesh are cut away by experienced workmen. The hides are then put into cold water to "plump" them, and are then put into "handlers," or vats containing the tanning solution. After 12 days they are put into "layways," or vats, where the hides are piled, with bark spread between them, and which are then filled up with tanning liquor. The tanning liquor may be changed five times or more, depending on the grade of leather to be made, using stronger liquor each time. If the leather is to be used for belting butts, after passing through the "handlers" the bellies are trimmed off with sharp knives. The bellies are then used for making



PLAN, END AND FRONT ELEVATION OF VACUUM DRUM DRIER

sole leather. After a preliminary drying process the bellies, having gone through the layways, are dipped in water and oiled, and are then passed through a roller and rolled into sole leather—irregular-shaped strips about a foot wide and 6 ft. long. The sole leather goes to a drying loft.

After treatment in the layways the belting butts (or hides with the bellies and shoulders cut off) are oiled with cod oil, and then are hung up in a dry loft, or "tunnel," through which air is blown, and dried for ten days, the temperature of drying being gradually raised to 95-100 deg. F.

The tannery making leather for sale in the general market sells it by the pound. It is therefore to the advantage of the tannery to add weight to its product. This is done without any unnecessary display or advertising by allowing the hides to spend a long time in some of the processes, and under this method of procedure, which benefits the leather manufacturer but does not improve the quality of the leather, six months are consumed in transforming a hide into leather. . The complete process can, however, be done in two months; hence it is easy to see, from the greatly reduced amount of capital tied up in stock in process and the improved quality of material, the economies to be derived from the consolidation of a tannery with a factory for the production of finished leather goods.

The present capacity of the tannery is 125 hides per day, but under the new management this will soon be increased to 500 per day.

Lang-Grant Leather Corporation

As stated above, the tanning extract plant and the tannery have been purchased by the Lang-Grant Leather Corporation, which is now building and will operate, in conjunction with the existing plants, extensive additions to the present tannery, and a large new plant for the manufacture of harness, saddles, horse collars and gloves. The capital stock of the new company is $4,000,000. The enterprise will operate under the management of J. Harry Lang and R. Y. Grant. A site of 12 acres has been secured for the plant buildings. The building now being constructed is four stories high, 440 ft. long by 120 ft. wide, with two wings, 64 ft. by 50 ft., and 35 ft. by 70 ft. respectively, both three stories high. The building in which the saddlery will be manufactured will be 1200 ft. long by 100 ft. wide. The new buildings will be constructed of brick and concrete, the building materials being all made in Kingsport.

An idea of the magnitude of the proposed operations is gained from the statement that 400 tons of rye straw, locally grown, will be used annually in the production of horse collars alone. It is stated that the new enterprise when completed will employ 1200 to 1500 men, more than half of whom will be skilled mechanics. It can easily be realized that there is already great activity in the building of dwellings for housing the expected large increase in the population of the city.

Kingsport Pulp Corporation

The plant of the Kingsport Pulp Corporation was built in 1916-17, and was first operated in 1917. The capital stock of the company is $1,000,000. The principal officers are: President, Royal B. Embree; treasurer, J. C. Stone; general manager, J. H. Thickens; mill manager, J. E. Wetherbee. The plant was designed by George F. Hardy of New York City.

The reasons for the location of the plant at Kingsport, aside from the cheap power available, were existence of the tanning extract plant, which could supply 50 per cent of the raw material needed, in the form of extracted chestnut wood chips, and the abundance of hard woods in the vicinity, which would provide the other 50 per cent. The kinds of wood used, besides the chips from the extract plant, are poplar, cucumber and black and sweet gum. The capacity of the plant is 100 cords of wood a day.

The first step, as applied to the cord wood, is the stripping of the bark. This done, the wood goes to the chipper house, where it passes through a chipper made by the Carthage Machine Co., Carthage, N. Y., and under the chipper to a bucket elevator, which elevates the chips to a revolving screen, also manufactured by the Carthage Machine Co. This screen is a double one, and is shaped like the frustum of a cone, lying on its side. It is 30 ft. long by 4 ft. in diameter at the upper end, enlarging to 9 ft. at the lower end, and is placed at a pitch of 4 ft. in 30 ft. of length. The inner screen has meshes of 1½ in., the outer one, ¾ in. Sawdust escapes through the outer screen and goes to the boilers. The chips remaining on the inside of the inner screen go to a crusher, where they are reduced in size, and then join the chips which are caught between the two screens, going by conveyor to a bucket elevator, by which they are hoisted to the chip bins, which have a capacity of 100 cords of wood, or sufficient for one day's run.

The next step is digestion of the chips with caustic soda solution. There are ten digestors, built by the American Welding Co., of Carbondale, Pa., and made of seamless welded steel ⅝ in. thick, each 7 ft. in diameter by 30 ft. high. A solution of caustic soda is made, by treating soda ash with lime, in a Dorr system of tanks, six in all, each 30 ft. in diameter by 10 ft. deep. This is a continuous causticizing process. The strength of the solution as used in the digesters is 12 deg. B. The digester is charged with five cords of chips and 3500 gal. of caustic liquor, and is then sealed air tight.

The mass is then cooked with steam injected into the solution under a pressure of 110 lb. for 7¾ hours. At the end of that time the entire contents of the digester escape through a valve at the bottom into a blow-tower on the roof, being blown up there by the steam pressure in the digester. From the blow-tower the pulp goes to any one of four wash pans. These are of steel, and are 16 ft. in diameter by 7 ft. deep, fitted with a perforated false bottom which allows the liquor to drain off and retains all the pulp. The liquor goes back to the recovery process for the recovery of caustic soda. The pulp is washed for five or six hours, and is then delivered to the screen room. The wash water is discharged into the sewer.

The screen room contains eight screens, which are rectangular boxes about 10 ft. long by 4 ft. wide by 1 ft. deep, whose bottoms consist of ten brass plates, each a foot wide, containing many narrow slits 4½ in. long by 10/1000 in. in width. This screen, called the Improved Packer Pulp Screen, is made at Hudson Falls, N. Y. The wood fiber is drawn through the narrow slits by vacuum, the vacuum being alternately applied and released 700 times a minute by special machinery. All the fiber suitable for pulp making goes through the slits, and the oversize is rejected and goes to waste.

The material passing through the screen consists of 99.5 per cent water and 0.5 per cent fiber. This liquid goes through an iron pipe to one of two Decker-Wet

machines, manufactured by the Thompson Manufacturing Co., Lancaster, N. H. Here all trace of soda ash, lime, etc., is washed out, and the mass is brought to a concentration of 90 per cent water and 10 per cent fiber. The pulp now goes to the Belmer bleachers, of which there are six, manufactured by the Thorn & White Co., Philadelphia, Pa. Here a bleaching powder solution, 3.5 deg. B. in strength, is added. The function of the Belmer machine is to cause a continuous circulation of the stock through a system of tanks, during the bleaching process, which requires about five hours. After the bleaching is completed, the stock is dumped into one long tank, which extends under all six of the bleachers. The stock is then washed again, over a triple Decker-Wet machine, and then goes to a pulp-drying machine built by J. H. Horne & Sons Co., Lawrence, Mass. Here the pulp passes through an elaborate system of rolls, some of them steam-heated, by which it is dried, and is then cut into suitable sizes and rolled into bundles suitable for shipment.

The output of this plant is 50 tons of pulp a day. The quality made is excellent, the color a pure white, and it is used by paper makers for the manufacture of calendared paper such as is used by the better class of magazines.

Recovery of Caustic Soda

The liquor escaping from the false-bottomed tanks in the wash room is piped to two Yaryan evaporators, made by the Yaryan Co. of New York City. This type of evaporator is a 22-coil, triple effect machine. The first effect operates under 30-lb. pressure, the second effect under 9 in. of vacuum, and the third effect under 24 in. of vacuum. The solution enters the evaporator at 5 deg. B., and is discharged at 35 deg. B. It then goes by pipe line to a tank, and thence flows to one of two incinerators, where all water is expelled and the mass is burned to black ash. The incinerator is a revolving steel cylinder, on its side, 12 ft. in diameter by 15 ft. long, lined with 8 in. of fire brick. The woody matter of the caustic solution is burned at a very high temperature, said to be 2500 to 2800 deg. F. The recovery of black ash per day amounts to 60,000 lb., equivalent to 75 to 90 per cent of the caustic soda used. The black ash is distributed to leaching cells, where it is leached under 25 lb. pressure, and the solution is returned to the causticizing room, where it is used in the production of cooking solution.

The recovered solution as received at the mixing tanks in the causticizing room is of various strengths. Quicklime and soda ash are added to bring the solution to the strength desired. For mixing the caustic solution there are three steel mixing tanks, 9 ft. deep by 11 ft. in diameter, each provided with agitators, and perforated basket for slaking the lime. When the solution strength is properly adjusted, it goes to the Dorr system of tanks previously described.

The proper proportions for making caustic soda, assuming no recovered black ash solution to be used, are 5500 lb. of soda ash to 5650 lb. of quicklime. The quicklime is obtained from the neighboring plant of the Clinchfield Portland Cement Co. The actual consumption of quicklime per day is 50,000 to 55,000 lb., and of soda ash, 12,000 to 15,000 lb., the consumption of the latter being greatly reduced by the use of recovered black ash.

This concludes the description, necessarily brief and incomplete, of Kingsport and its chemical industries. One can hardly fail to notice how the plants are linked to one another. The utilities company supplies all the plants with power, and with water for drinking and fire purposes. The brick and cement companies supply themselves and all the rest with building materials. The dye works produces dye for the hosiery mill, and bleaching powder for the pulp mill. The cement plant furnishes lime for the industrial alcohol plant, the dye works, the tannery and the pulp mill. The extract plant supplies tanning extract for the tannery and extracted wood chips for the pulp mill, and the tannery will provide the new saddlery and harness factory with leather. If co-operation is the life of trade, the industries of Kingsport should thrive indeed.

Opportunity must be taken here to express appreciation of the courtesies extended by J. Fred Johnson, president of the Kingsport Improvement Corporation; by S. P. Platt, assistant to Mr. Johnson, and by the several managers and superintendents of the Kingsport plants who made possible this description of the chemical industries of an interesting community.

Imports and Exports

The Bureau of Foreign and Domestic Commerce of the U. S. Department of Commerce reports for March, 1919:

IMPORTS OF LEAD AND ZINC INTO THE U. S. BY COUNTRIES, AND FOREIGN AND DOMESTIC EXPORTS FROM THE U. S. TO ALL COUNTRIES

Synopsis of Recent Chemical and Metallurgical Literature

Electrometallurgy of Molybdenum.—According to an article by J. ESCARD in the *Revue Générale de l'Electricité*, Vol. IV, No. 11, Sept. 14, 1918, molybdenite, MoS_2, is treated in an electric furnace for molybdenum either directly or with molybdenum dioxide.

I. Direct Treatment of Molybdenite. The molybdenite is simply heated in an electric furnace and a fairly pure molybdenum is obtained. In heating a mixture of molybdenite and molybdenum dioxide in the electric furnace the following reaction takes place:

$$MoS_2 + 2MoO_2 = 3Mo + 2SO_2$$

and the product obtained has about 98.5 per cent Mo, with only about 0.7 per cent sulphur. When the mixture of molybdenite, carbon and lime is heated in the electric furnace the reaction is:

$$MoS_2 + 2C + 2CaO = Mo + 2CaS + 2CO$$

but this molybdenum still contains 3 to 4 per cent sulphur. When treating in a resistance furnace a mixture of molybdenite, lime and calcium fluoride, the product obtained is Mo_2S_3 if the current is high, 600 to 800 amperes and 110 volts, but with a current of 70 to 100 amperes and about 35 volts, and eliminating the iron with hydrochloric acid, the product obtained is 98.95 per cent Mo and 0.67 per cent Fe.

II. Treatment of Molybdenum Dioxide. The molybdenum dioxide is reduced with carbon. The following reactions take place:

$$2MoO_2 + 5C = CMo_2 + 4CO$$
$$2CMo_2 + MoO_2 = 5Mo + 2CO$$

The product obtained has one of the following compositions:

	No. 1	No. 2	No. 3
Molybdenum	99.98	99.73	99.78
Carbon	0.00	0.01	0.00
Slag	0.13	0.28	0.17
	100.11	100.02	99.95

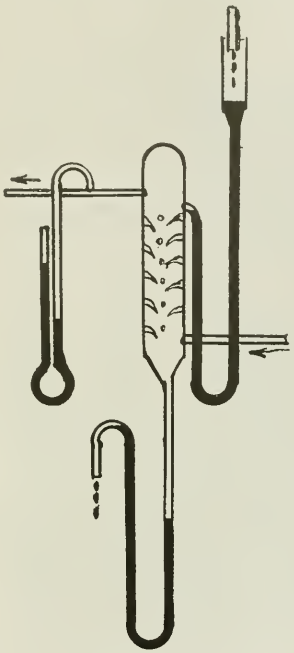
The molybdenum dioxide can be replaced by calcium molybdate in the presence of alumina when admixed with molybdenum carbide, as per the reaction

$$9CMo_2 + 3MoO_4Ca + Al_2O_3 = 21Mo + Al_2O_3 \cdot 3CaO + 9CO$$

In the preparation of electric wires the carbon filaments are subjected to the thermic action of an electric current in the presence of hydrogen in an atmosphere of molybdenum pentachloride ($MoCl_5$). This is transformed into molybdenum carbide, then finely pulverized molybdenum dioxide is added and the same reaction as above takes place, giving the pure molybdenum metal.

Continuous Testing of Gas With Special Reference to Acid or Alkaline Constituents.—In the course of working a plant for the recovery of ammonia from Mond gas, the need was felt for some form of apparatus which would indicate at any time whether complete absorption of ammonia was being effected, or whether some ammonia was passing through the plant, with consequent loss in the recovery of ammonium sulphate. The apparatus devised is described by C. A. KING in the *Journal of the Society of Chemical Industry*, London, England, Feb. 15, 1919, which serves for the continuous testing of alkalinity or neutrality of a gas.

The gas from the outlet main is caused to pass upward toward a small glass absorption chamber about 7 cm. long and 1.5 cm. diameter, provided with projections from the inner wall to effect more efficient contact with a solution of a suitable indicator which flows from a U-shaped tube into the upper end of the extraction chamber. The indicator solution drains away from the lower end of the absorption chamber through a similarly shaped tube in which any change in color of the solution is noted. The inlet and outlet bends are of such length that the solution forms a liquid lute against the pressure of the gas in the apparatus.



APPARATUS FOR CONTINUOUS TESTING OF GAS

The indicator used is a solution of methyl red with sufficient acid added just to develop the true red color of the acid indicator. The color change from red to yellow (in alkaline solution) can be readily observed by artificial light. Complete absorption of ammonia takes place with a flow of gas through a 2-mm. diameter jet (about 5 cu.ft. per minute), and with the indicator solution set at a fast dropping rate a very sensitive indication can be obtained.

The apparatus is used qualitatively, but with suitable calibration it might be employed for approximate quantitative estimation. It is suggested that a similar form of apparatus might be conveniently used for other purposes, for example the detection of acid vapors in chimney gases. But it can only be used where colorimetric tests can be applied owing to the fouling of the observation tube by anything in the nature of an adherent precipitate. Another possible application is for the detection of CO using the iodine pentoxide method in which the iodine liberated is absorbed by a continuous stream of potassium iodide solution to which are added a few drops of starch solution as an indicator. The arrangement as shown is made especially to obviate siphoning of the entering liquid, though under certain conditions siphoning at intervals might be a distinct advantage.

Mechanical, Micrographic and Macrographic Properties of Alloys High in Zinc.—MESSRS. LEON GUILLET and VICTOR BERNARD have studied mechanically, micrographically and macrographically the alloys high in zinc (*Revue de Metallurgie*, 15, No. 5, Sept.-Oct., 1918). Their aims were: 1. To determine the influence of copper and aluminium on the properties of zinc. 2. To examine some ternary alloys Zn-Cu-Al. 3. To study

the variation of the properties of the alloys with temperature, and to determine the temperature optimum for their forging and working.

A. The results of the mechanical tests are summarized as follows:

According to the purity of the zinc, and especially with its content of lead, the mechanical properties of rolled zinc are:

Breaking strain $R = 15$ to 16 kg.
Extension $A = 35$ to 47 per cent

The cast alloys do not present any interesting feature. An alloy with 8 per cent copper has a breaking strain of 17 kg., but the elongation and resilience are nil. A rolled alloy of 3 per cent aluminium has a breaking strain of 23 kg. and an elongation of 15 per cent. A rolled alloy of 2 per cent aluminium and 3.6 per cent copper has a breaking strain of 32 kg. and an elongation of 5 per cent. When drawn down the alloys generally show a higher breaking strain and a greatly increased elongation. Thus:

Alloys		Breaking Strain R	Elongation, Per Cent A	Resilience S
2.5 per cent Al	Rolled	22.0	4.4	1.2
	Drawn	25.9	26.4	2.5
1.3 per cent Cu	Rolled	23.0	1.5	1.8
	Drawn	30.5	27.9	1.9
4.2 per cent Cu	Rolled	30.5	7.3	1.2
	Drawn	33.5	22.0	1.6
2.1 per cent Al, 3.6 per cent Cu	Rolled	32.1	4.4	1.2
	Drawn	37.4	16.1	1.2

The drawn alloys possessing somewhat similar mechanical properties to drawn brass ($R = 28$ to 32 kg. $A = 30$ to 25 per cent, $S = 3$ to 5) are:

Alloy: Ordinary zinc (1 to 1.2 per cent Pb) 97.5 per cent to 98 per cent, copper 1.5 per cent to 2 per cent with $R = 30$ to 31 kg., $A = 27$ to 28 per cent, $S = 2$.

Alloy: Ordinary zinc (1 to 1.2 per cent Pb) 88 per cent, copper 4 per cent, aluminium 8 per cent with $R = 36$ kg., $A = 24$ per cent, $S = 1.2$. It is to be noted that the resilience of these alloys is much smaller than that of brass.

B. The results of the micrographic examinations are summarized as follows:

Zinc-aluminium alloys. These two metals form two solid solutions, one containing 0 to 4 per cent Al and the second from 50 to 100 per cent Al. These two solutions form a eutectic which corresponds to 5 per cent Al. It has been found that a eutectic is formed in an alloy with only 1 per cent Al. This is probably due to heterogeneity of the alloy.

Zinc-copper alloys. In these alloys there is a solid solution η when the percentage of copper is at the most 2.5 and two solid solutions, one η and another ε, when the percentage of copper is between 2.5 and 13. The solution ε increases with the percentage of copper; it gives rise to brittleness and its formation should be avoided by limiting the percentage of copper.

Zinc-aluminium-copper alloys. A complete examination of the Zn-Al-Cu alloys has not yet been made, but it appears that the solid solutions of zinc with aluminium and of zinc with copper are formed independently. The constituent ε increases with the percentage of copper, the eutectic also increases. The properties of the alloys correspond with the separate properties of these solutions. This explains the remarkable properties of the alloy zinc 88 per cent, aluminium 8 per cent, copper 4 per cent, in which the eutectic of the two solutions predominates (to which correspond the properties $R = 27$ and $A = 27$ per cent) and a certain quantity of ε which increases the hardness.

C. The results of the macrographic examinations are summarized as follows:

1. In cast samples the macrographic examination reveals large elongated crystals. The constituents observed in the micrographical examination are generally visible and sometimes distributed heterogeneously. 2. In rolled samples the crystal structure is not apparent, but the heterogeneity is often revealed. 3. In drawn samples the transverse as well as the longitudinal sections show defaults of homegeneity in the center. They cannot be eliminated by annealing. This point deserves careful consideration. The mechanical properties of the alloys vary with the temperature, the elasticity increasing very rapidly between 100 deg. C. and 150 deg. C. The optimum temperature for forging and working the alloys is 125 to 130 deg. C.

The conclusion is that of all the alloys high in zinc only two deserve special attention, namely:

Alloy: Ordinary zinc 98 per cent, copper 2 per cent, with $R = 30$, $A = 28$ per cent, $S = 1.9$.

Alloy: Ordinary zinc 88 per cent, copper 4 per cent, aluminium 8 per cent, with $R = 36$, $A = 24$ per cent, $S = 1.2$.

Electrometallurgical Treatment of Nickel Ores in New Caledonia.—The electrometallurgical treatment of the New Caledonia nickel ores has not given satisfactory results until lately in regard to the production of a ferronickel low in carbon and silicon. Mr. M. SABATHIER gives in the *Journal du Four Electrique*, 28, No. 1, Jan. 1, 1919, the method used at Taô, on the eastern coast of New Caledonia, for treating garnierite in an electric furnace, by which he obtained a product containing less than 0.5 per cent carbon and about 0.2 per cent silicon.

The ore treated is a garnierite of the following composition:

	Per Cent		Per Cent
SiO_2	53.10	Al_2O_3	0.50
NiO	6.62 (5.20 Ni)	CaO	1.70
		MgO	15.30
Fe_2O_3	12.68 (8.85 Fe)	Loss on ignition	9.90
			99.80

The principle of the method is to heat the ore with carbon, whereby the total nickel oxide and part of the iron oxide are reduced; the non-reduced iron oxide becomes a part of the slag, while the reduction of silica is avoided by the use of lime giving a basic slag. The charge is composed of:

(a) Run of mine ore, which contains 20 to 25 per cent moisture.

(b) Powdered charcoal in a well-defined porportion to reduce the total nickel oxide and part of the iron oxide.

(c) Lime in proportions to give a basic slag.

A 400-kw. furnace is used. Two electrodes are used which are in series. The product obtained is a ferronickel of 50 per cent Ni with a maximum of 0.5 per cent C (the usual percentage being about 0.05 per cent C) and about 0.2 per cent silicon.

The electric energy consumed per ton of ferronickel 50 per cent Ni is 13,000 kw.-hr., with electrode consumption of 125 kg. There is a 2 to 3 per cent loss of nickel in the slag. When producing a ferronickel of 75 per cent Ni the carbon percentage is even smaller than for the 50 per cent Ni ferronickel, the percentage of silicon is the same, which is about 0.2 per cent, but the loss of nickel in the slag is 4 to 5 per cent of the total nickel in the charge.

Recent Chemical and Metallurgical Patents

Briquetting Brittle Metals.—F. A. VOGEL of New York City notes that the Ronay system of briquetting operates very well on many metals, but does not press brittle borings into a coherent mass. The Ronay process operates in such a manner as to cause attrition between contiguous metallic surfaces under conditions which exclude air or other film. Molecular cohesion then seems to unify the particles into almost an integral mass. Borings or turnings of steel are usually covered with oil, soap or other foreign matter which tends to prevent such particles from coming into direct contact. Brittle borings are, therefore, first reduced in size by grinding in an edge runner and then heated to a point which not only will burn any carbanaceous foreign material, but also after a slow cooling will bring the particles into a dead-soft anneal. Thereupon such metallic particles can be made into coherent briquets by the Ronay system. (1,299,878; assigned to General Briquetting Co., Apr. 8, 1919.)

Zinc Leaching.—H. L. SULMAN and H. F. K. PICARD of London, England, note that in the leaching of oxidized or roasted zinc ore with sulphuric acid it is extremely difficult to neutralize the last amounts of free acid solely by agitation with ore. They, therefore, propose to start with a solution containing approximately 10 per cent of sulphuric acid, and when the free acid has been reduced to from 1 to 2 per cent by successive additions of ore, the neutralization is completed by zinc hydrate. This pulp is then agitated at a high temperature to precipitate soluble silica in granular form when the zinc solution is separated from the various insolubles by filtering in the ordinary way. The filter cake still contains considerable soluble zinc which is removed by wash water—this wash water, however, is not added to the original solution, but is agitated with milk of lime. In this manner zinc hydrate and calcium sulphate are precipitated from the solution and are used as above noted to neutralize residual acidity in the leaching solution. (1,295,080; assigned to the Metals Extraction Corporation, Ltd., of London, England, Feb. 18, 1919.

High-Phosphorus Slag.—WILLIAM R. WALKER of New York City notes that American iron ores are so low in phosphorus that when the resulting pig iron is refined, the resulting slag is very low in phosphates, owing to the fact that so much lime must be added to flux the silicon. In order to produce phosphate slag containing at least 13 per cent of soluble phosphates, he first treats the iron in an acid bessemer converter. Here the silicon is reduced to small traces and the skimmed metal then transferred to a refining furnace, such as an open-hearth or an electric furnace. A basic slag is then made up which rapidly absorbs phosphorus from the bath. When the slag contains the greater part of the phosphorus, as much of it is withdrawn as is convenient and a second or finishing slag is added to complete the refining operation. The first slag may contain upward of 18 per cent phosphate, soluble in citric, and is therefore available as a fertilizer. The second slag is relatively low in phosphorus, but is high enough in calcium and iron so that it can be recharged in a blast furnace, thus recovering its phosphorus. (1,299,072; Apr. 1, 1919.)

Hardening-Machine.—C. C. JACKMAN and R. S. SQUIRE of Springfield, Mass., have patented a hardening machine especially adapted for the treatment of continuous objects such as wire or other long narrow objects which can be linked together in a continuous chain. During hardening such a chain is passed

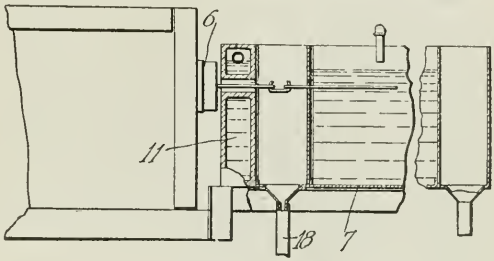


FIG. 1. HARDENING MACHINE

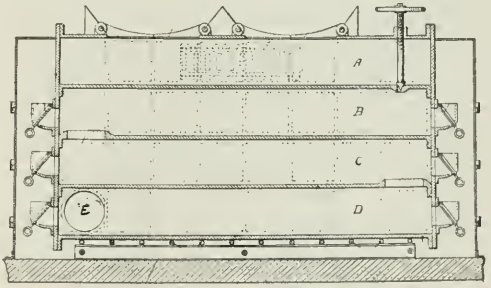
through an annular heating furnace of correct design, and on emerging from the furnace at 6 (Fig. 1) passes directly into the quenching tank 7. The quenching oil necessarily flows out of the tank through the slot by which the heated metal enters. Such oil is drained off through pipe 18, but the spray thrown up by this spashing oil has in the past quite often caught fire from the red-hot furnace, with disastrous results. The inventors, therefore, interpose between quenching tank and furnace the water-cooled jacket 11, which effectually prevents such fires. (1,299,949; assigned to Massachusetts Saw Works, Apr. 8, 1919.)

Down-Draft Sulphur Burner.—The burner shown in the accompanying illustration consists of four chambers, *A*, *B*, *C*, *D*. The uppermost, *A*, serves as a supply chamber for the sulphur, which is melted by the heat



DOWN-DRAFT SULPHUR BURNER

of the burning sulphur below. By means of the valve, liquid sulphur is run into the lower compartments which are connected by the openings shown at the left and right ends, respectively, of *B* and *C*. Since the upper rim of these openings is raised, a layer of melted sulphur will be retained in *B* and *C*, while the excess will collect in *D*. Air is supplied through the adjustable dampers, three of which are shown at each end, and the sulphur dioxide is drawn out through the pipes, *E*. Thus the sulphur dioxide takes the course which it would naturally pursue, since it is heavier than air. The whole furnace is surrounded by a jacket having sliding

dampers (shown in dotted lines in the center of *A*) through which the air supply must pass while the burner is in operation, the object being to preheat the air by contact with the hot walls. Numerous peepholes are provided so that the color of the flame may be observed and the air regulated accordingly. It is claimed that sublimation is avoided by this construction. (1,303,348; AINWELL G. MCINTYRE; May 13, 1919.)

Aniline Hydrochloride.—Since aniline hydrochloride is less soluble than aniline in benzene, toluene, carbon tetrachloride and similar solvents, the hydrochloride is obtained as a pure white precipitate when dry hydrogen chloride is passed into or over a solution of aniline in any of these solvents. CHARLES AHLUM of Chester, Pa., claims that this process not only gives a lighter colored product, but also obviates the necessity of repeated filtrations and concentrations, with their accompanying losses due to decomposition of the salt and the frequent handling required. (1,303,624; assigned to E. I. du Pont de Nemours & Co.; May 13, 1919.)

Spur Gear Speed Reducer

GEAR speed reducers are being employed extensively for driving elevators, conveyors, driers, pumps, agitators, mixers, screens and many other classes of machinery where it is customary to use a considerable reduction in speed between the motor and driven unit. They have also found a useful application and have rapidly gained favor for line-shaft service. On many belt-driven line-shaft installations, the main line drive pulley is nearly double the size of any other pulley on the shaft, which makes it necessary to provide hangers of sufficient depth to clear the drive pulley, while if a gear speed reducer were used it would be possible to use shorter hangers throughout the entire length of the line shaft, thus making an initial saving, besides providing a much more rigid drive as well as effecting a saving in overhead space.

Although for line-shaft drives the ratio is comparatively low, rarely exceeding 9 to 1, the first cost of the speed reducer will often be less than for any other complete drive, taking everything into consideration. Besides this, it will frequently be found practicable to use high speed motors, which are less expensive than slow speed motors and are generally more efficient.

The W. A. Jones Foundry & Machine Co. of Chicago manufactures a single and double type speed reducer, the single having reductions up to 15 to 1 and the double up to 200 to 1. Standard equipments as high as 200 hp. are built. The high and low speed shafts are concentric, joined through a flexible coupling and have the same rotating direction.

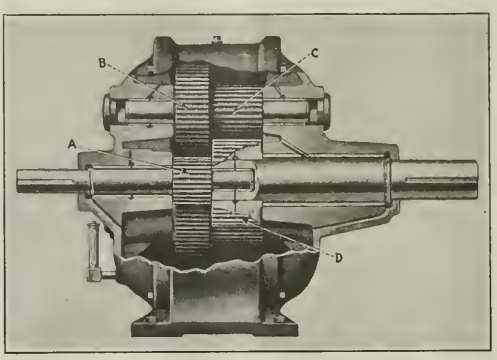
A few of the advantages claimed for these reducers are:

1. They occupy less space than other devices necessary to accomplish the same ratio of speed reduction.
2. Acid fumes, abrasive dust or other adverse atmospheric conditions do not affect their successful operation.
3. Shafts and bearings are relieved of all cross strains and transverse loads.
4. Slide rails and adjustments for correct center distances are unnecessary.
5. They require practically no attention and are quiet, efficient and durable.
6. The decrease installation costs.
7. All safety laws are complied with: There are no exposed moving parts that will cause injury to workmen.

Referring to the accompanying illustration, it will be seen that the pinion *A* meshes with and drives the three gears *B* which are mounted integral with the three pinions *C*. These in turn mesh and drive the slow speed gear *D*.

The gears *B* and pinions *C* are equally spaced around the high and slow speed pinion and gear at angles of 120 degrees, thus relieving both high and slow speed shafts and bearings of all transverse loads due to tooth thrust.

The high speed shaft and pinion *A* are forged from one piece of special analysis nickel steel. The pinion *A* is amply supported in correct alignment at one end by the bronze bushed bearing in the reducer housing,



SPUR GEAR SPEED REDUCER

and on the other end by the slow speed shaft extension which carries a bushed bearing.

All gears and pinions are finished from steel forgings, the accurately generated teeth being of the involute stub form with 20 deg. pressure angle, which insures great strength, maximum efficiency and long life. All shafts are accurately ground to size and are supported in heavy bronze bushed bearings, which insures correct alignment and proper meshing of the gear teeth. The splash system of lubrication automatically insures a copious supply of lubricant at all times.

Personal

MR. WALTER ARTHUR, formerly chief chemist and metallurgist with the Garfield Motor Truck Co., Lima, Ohio, has accepted a similar position with the Haynes Automobile Co., Kokomo, Ind.

MR. C. D. BALL, JR., has been discharged from the Chemical Warfare Service and resumed his duties as instructor in chemistry at the Michigan Agricultural College, East Lansing, Mich.

MR. RALPH V. DAVIES is now in the technical control department of the Aluminum Co. of America, New Kensington, Pa.

MR. F. W. DEARBORN, formerly of the Ordnance Department, is now on the staff of the Bureau of Standards, where he will be engaged especially in research on the chemistry of cellulose.

MR. JOHN T. FULLER has accepted a position with the American Bauxite Co., Bauxite, Ark.

Dr. John A. Mathews, president of the Halcomb Steel Co., Syracuse, N. Y., sailed for Europe recently as a member of the War Department's Aircraft Standardization Committee, headed by Assistant Secretary Crowell, to study the standardization in aircraft building in Europe.

Mr. H. W. Morse gave an illustrated talk before the San Francisco section of the American Chemical Society on May 19 on the manufacture of potash and borax at Searles Lake, California.

Mr. Floyd W. Parsons has resigned as editor of *Coal Age* to accept a position with the *Saturday Evening Post* as head of the business and science department.

Mr. S. F. Shaw has accepted a position as superintendent of the Charcas Unit, National Metallurgical Co., Charcas, Mexico.

Dr. William H. Walker has received his discharge from the United States Army and is returning to civil life at his home in Bridgton, Me. Dr. Walker was commissioned Colonel in the Chemical Warfare Service and had charge of the Edgewood Arsenal.

Prof. Waturo Watanabe has retired from the post of professor of mining and metallurgy, as well as the director of the Engineering College, and has been elected emeritus professor of the Imperial University, Tokyo, Japan.

Mr. Robert E. Wilson has accepted a position as assistant director of the research laboratory of applied chemistry and assistant professor of chemical engineering in the Massachusetts Institute of Technology, Cambridge, Mass.

Mr. Louis E. Wise, formerly of the Bureau of Chemistry, has resigned to accept a position with E. I. du Pont de Nemours & Co., Wilmington, Del., as organic research chemist.

Mr. Harry J. Wolf has resigned his position as professor of mining, Colorado School of Mines, to accept a position on the editorial staff of the *Engineering and Mining Journal*.

A State Bureau of Mines at Butte has been organized with Mr. C. H. Clapp as director and geologist, Mr. H. B. Pulsifer as metallurgist and Mr. A. E. Adami in charge of the department of mining engineering.

Current Market Reports

The Non-Ferrous Metal Market

Tuesday, June 10.—Prices have taken a firm tone. Copper appears to have gained its normal market equilibrium and will probably not fluctuate much above or below 17½c. in the near future.

Aluminium:—A good volume of business is reported at 33c. per lb. on 98-99 per cent ingots. Scrap sales are reported as follows: Cast, 20-23c.; sheet, 20-23c.; clippings, 22½-26c. Sheets 18 gage and heavier, 42c. Powder, $0.70-1.40 lb.

Antimony:—There is a slight shortage in antimony supplies, wholesale spot bringing 8¾c. and future 8-8¼c. lb. Job lots, 8⅝c. lb.

Copper:—The advance in copper has settled at 17⅜-17½c. lb. with no lower offers on futures. Scrap is bringing from 12 to 16c.

Copper sheets, hot-rolled	lb.	$0.24	— .....
Copper sheets, cold rolled	lb.	.25	— .....
Copper bottoms	lb.	.23½	— .....
Copper rods	lb.	.21	— .....
Copper wire	lb.	.18	— $0.18½
High brass wire and sheets	lb.	.19½	— .....
High brass rods	lb.	.18½	— .....
Low brass wire and sheets	lb.	.21½	— .....
Low brass rods	lb.	.22½	— .....
Brazed brass tubing	lb.	.30½	— .....
Brazed bronze tubing	lb.	.35	— .....
Seamless copper tubing	lb.	.29	— .....
Seamless bronze tubing	lb.	.35	— .....
Seamless brass tubing	lb.	.30	— .....
Bronze (gold) powder	lb.	1.00	— .....

Lead:—Lead is very stable. New York asks 5½c. and E. St. Louis 5c. lb. Sheet lead has advanced to 8¼c. lb.

Tin:—A complete liquidation of the 72½c. tin allocation is expected in the fore part of July.

Zinc:—Spelter has had a slight rise in New York, to 6⅝c., with futures up to 6¾c.; E. St. Louis, 6¼c. with August futures at 6½c.

OTHER METALS

Bismuth	lb.	$3.20	— $3.65
Cadmium	lb.	1.40	— .....
Cobalt	lb.	2.50	— 3.50

Mercury	75 lb.	92.00	— .....
Nickel	lb.	.40	— .45
Iridium	oz.	175.00	— .....
Palladium	oz.	115.00	— 120.00
Platinum	oz.	105.00	— .....
Silver	oz.	1.10⅜	— .....

The Iron and Steel Market

The improvement in steel demand that began May 10 or 15 and made good progress during the second half of the month gained only a little additional headway during the first half of June. There was no retrogression, however, in any branch of the finished steel trade, and demand for some products, particularly sheets and merchant steel pipe, increased very considerably.

It is the common opinion that the movement has not gained sufficient momentum to carry it through what is normally the dull summer period. In recent years it was only in 1915 that there was a really active market in July and August, and in that year the foundation for the greatest rise in steel market history was being laid. Should the steel market become relatively dull in July and August, however, the probability would be of a fresh movement starting in early autumn of greater proportions than the one now being experienced.

Production Heavier

Production of pig iron during the first half of June was at a rate of fully 25,000,000 tons per annum, or a rate slightly in excess of the rate in the latter part of May. Up to that time there had been a continuous decrease in pig iron production, but the turn seems to have occurred. High humidity in the midsummer period would decrease the rate of production as to the furnaces actually in blast, but such a decrease would be only a temporary and seasonal affair. Pig iron production at 25,000,000 tons a year means 58 per cent of capacity if capacity be taken at 43,000,000 tons a year, and 56 per cent if capacity be taken at 45,000,000 tons. The actual commercial capacity probably lies within these limits. Steel ingot production is at approximately the same percentage of capacity. In the early months of the year pig iron production was at a much higher proportionate rate to capacity than was shown by steel. It is probable that steel mills having blast-furnaces were endeavoring to liquidate stocks of ore, while steel mills using purchased pig iron were endeavoring to work out contracts, thus using more than usual proportions of pig iron. With conditions fairly well liquidated in this respect, there is probably heavier consumption of scrap in steel making than formerly. Earlier in the year heavy melting steel scrap touched a low point of about $14.50, delivered Chicago, Pittsburgh or Philadelphia, there being scarcely any demand. At the beginning of June the market was approximately $16, and in the fore part of the month the Pittsburgh market advanced to $17. Scrap dealers describe the market as dull, but there has probably been quite heavy absorption of scrap, both by direct purchases of mills from railroads and other producers and by purchases of Government scrap lying in the mills' own yards.

Character of Demand

Those who doubt whether the steel trade can become really active until there is a radical change in conditions point to the fact that there is no railroad buying, and not likely to be any for deliveries this side of next spring, and also urge that there is little new construction work being undertaken, while railroad demand and general construction work always absorb much more than half the steel output when there is production at capacity. The theory seems plausible enough at first glance, but when one takes notice of the fact that the mills have been operating at 55 per cent or more of capacity he wonders how that can occur if more than half the steel demand is missing. When the operating rate is 55 per cent, the more customers there

are who are out of the market the better, for at some time or other they would have to come in, and there might not be room for them. The probability is that a fair amount of construction work is in progress despite the general appearance of dullness in that direction.

A factor in the present steel situation should be noted, that while in ordinary periods of activity there is well distributed demand from all quarters, the period of activity upon which the steel trade must enter at one time or another represents an accumulation of demand and it is not necessary that all classes of consumers should be equally active throughout this period of activity. Some consumers may fill the major portion of their accumulated requirements in a short time, others may buy little in the near future but a great deal more in the later future.

Steel Prices

It is a question whether there is more or less shading of steel prices now than there was before the recent increase in activity. The demand is not heavy enough to firm up prices, while when there is more inquiry there is more temptation to cut prices. Where there is shading, however, it rarely amounts to more than from $1 to $4 a ton, and the general foundation of the market is much firmer in this respect, that the cutting does not precipitate a break. Earlier in the year it was the feeling of many if not all steel producers that any yielding in the market would precipitate not merely a decline but a serious break. The whole bottom might drop out of the market. Nothing of the sort is now feared. The market is standing more or less on its own feet.

Pig Iron

Technically there has been an open market in pig iron since about April 1. It has been necessary for pig iron to adjust itself to commercial conditions, for the war-time price structure was altogether artificial. The normal condition is for pig iron to sell at higher prices in some producing districts than in others, according to variations in cost of production and the amount of pig iron that can be disposed of within a certain freight radius. Birmingham iron, for instance, has always had to penetrate into Northern markets and compete with Northern furnaces, and thus prices f.o.b. Birmingham were always lower than prices f.o.b. Chicago, Ironton, eastern Pennsylvania and other furnaces. The war control, however, gave Birmingham the full f.o.b. furnace basis. The $3 reduction in December, 1918, and the $4.25 reduction proclaimed as effective March 21 did not touch the war-time basings. Birmingham iron has now declined so as to be more or less competitive with Northern iron. The March 21 price on foundry iron 1.75 to 2.25 per cent silicon was $26.75, while Birmingham iron is now available at $23.50, furnace. Some of the Lake front furnaces have cut prices in order to sell in distant markets, while endeavoring to hold prices as to their own local markets, and the same is true of southern Ohio furnaces. Taking the pig iron market as a whole, however, the decline has been very slight and it is quite improbable that there will be any large decline in the near future. The merchant furnaces have met the situation of light demand by blowing out. Predictions are beginning to be made of advances for pig iron in the near future, but such predictions are not in keeping with market history. When there are many furnaces out the pig iron market experiences the greatest difficulty in scoring an actual advance. At successive intervals idle furnaces come into blast, each furnace first selling some pig iron at any price obtainable to furnish the desired "back log."

General Chemicals

New York, June 9, 1919.

The firmer tendency noticeable is due in great part to the increasing influence of manufacturers. Many chemicals which have been selling in second hands at a figure far below the present cost of production are now entirely absorbed, leaving manufacturers largely in control of the situation. Particularly is this true of caustic soda, soda ash, bleaching powder and barium carbonate. Export inquiries continue in good volume. Spain, Denmark and South America show particularly satisfactory developments in this respect.

Large shipments of caustic soda continue to be made, Japan and South America being the heaviest buyers. This steady demand has absorbed material in second hands with a resulting stronger market. Acetic acid shows a decline, manufacturers having reduced their schedules to stimulate sales. Citric acid holds a much stronger position due to the recent warm weather and the consequent extra demand in the face of limited supplies.

Muriatic, sulphuric and nitric acids are receiving a good demand. Much of the muriatic is being shipped to Cuban sugar manufacturers, while the call for sulphuric comes chiefly from South America. Excess supply has caused pyrogallic to drop, being quoted now around $2.40 a pound.

Although most dealers have advanced slightly the price of bleach, there being no surplus stocks, one dealer is offering a lot of forty carloads at the low figure of $1.25 a cwt., New York.

Potassium carbonate shows an inclination to advance, some dealers having already jumped the price owing to demand from Denmark. Caustic potash remains unchanged, but is likely at any time to move in sympathy with potassium carbonate. Most of the potash products, however, are weak, owing to heavy competition with foreign goods.

When the Government relinquishes control of the price of sodium nitrate, on July 1, importers anticipate a reduction to $3.10 a cwt. from the present figure of $4.07½.

Coal-Tar Products:—The demand for crudes has increased during the interim and is confined almost entirely to domestic users. Benzol is particularly active with production cut. The price on pure water white is now 24-28c. per gal., the 90 per cent grade, 23½-27c. There will be little available spot stock of benzol until the close of July. Competition with the English product has caused a cut in cresylic acid.

The tendency on the part of intermediates to pick up, noted several weeks ago, continues and some manufacturers find difficulty in keeping up with the demand for some of the intermediates. The textile mills are beginning to consume dyes, with the result that dyemakers are increasing their demands for the coal-tar intermediates. Those receiving the heaviest call are alpha-naphthylamine, paratoluidine, paranitrotoluol and aniline oil. One manufacturer reports his entire output of paratoluidine promised to July on orders.

Waxes:—Most waxes have advanced in price. Spot stocks have been cleaned out with the result that offerings for shipment are light and the market is firm for futures.

Beeswax owes its advance to unprecedented demand and the limited arrivals of stock. The same with Japan wax.

A firm market in Brazil in conjunction with continued heavy demand here, in the face of a scanty supply, are the contributing factors in the jump of carnauba.

Although paraffine waxes have dropped still further in price, there is slight tendency toward a firmer tone. The difficulty with this commodity is that the demand by no means equals the production. However, it is believed that this condition will be overcome in a short time. A favorable sign is the increasing number of inquiries now coming from South America. Previously, the greater number of inquiries were from Europe. The demand from that source continues to hold fairly strong, while the domestic call is fair.

The recent warm weather has affected the production of stearic acid; causing an advance.

Oils: — Unabated European demand has continued to strengthen vegetable oils. England continues her heavy buying, with Sweden a close second. Domestic buyers are coming into the market for large quantities, apparently realizing that because of the huge export demand prices will undergo no reduction for some time.

There appears to be not so much a shortage of oils as that they are held in strong hands. This is attested to by the fact that several consignments of oils (part of the allocations made by the Government for Europe several weeks ago) were cancelled owing to late arrival at the docks and are now being held by the shippers. It is pre-

dicted, however, in some quarters that a scarcity may eventually be felt. For if England persists in her demand producers in the Orient will be likely to divert their supplies to the British market, thus forcing dealers here to rely on domestic crops, which may or may not meet the demand.

The expected advance in linseed oil has materialized and most dealers have increased previous quotations by three cents. The main factor in this condition is the scarcity of seeds and, in addition, dock strikes in Argentina have held up shipments of seed.

Of considerable interest to the local trade is the recent announcement by the Spanish government of an embargo on the export of olive oil during the present month due to shortage.

It is the belief of many dealers that this regulation will continue in effect throughout the summer. With present supplies of olive oil none too plentiful, an advance is anticipated shortly.

Decreasing stocks due to heavy demand and the fact that catches of oil producing fish are below normal and the fish less fat than last year offer the chief basis for the rising market on fish oils. Crude fish oils in particular are receiving a heavy call from Europe. England is now asking for 5000 bbl. of crude menhaden oil, without response, because producers are unwilling to hold the oil until shipping space can be obtained.

On the domestic side, with the leather, steel and paint industries gradually increasing production, the buying in these quarters is increasing in volume.

SHELLAC:—There is no noteworthy change in the shellac situation. Now and then a few bags appear on the market but are quickly bought up. Sales of a few packages of V. S. O. at $1.15 were reported this week, with dealers asking 90c. for orange superfine, and 80c. for A.C. garnet grade; bleached, bone dry is held at an even $1.00. No T.N. or D.C. is offered and the other grades in only a very limited quantity.

Although there were fairly heavy arrivals from Calcutta last week, the entire amount went to fill old orders. The arrival of the May steamers from Calcutta is expected within the next six weeks, but these shipments will likewise go to cover previous sales.

Contrary to earlier reports, information comes now that supplies in Calcutta are not as plentiful as was anticipated. It appears unlikely that the situation will be relieved before fall.

NAVAL STORES:—Eight years ago spirits of turpentine attained the high mark of $1.19 per gal. Following a daily advance, the price at this writing is $1.04-1.06, with indications of a further jump. Continued heavy demand from abroad with strong domestic buying is given as the reason. London is reported the heaviest buyer. Nearly all the old stocks have been sold and the South is being given no opportunity to accumulate stocks. There is practically no spot material to be found in New York.

St. Louis, Mo., June 9.

A decided increase in demand for certain of the heavy chemicals, particularly sulphuric acid, is reported by local producers. With this development, naturally, has come a firmer feeling and in some cases appreciable price advances.

The fact that the contract renewal season is close at hand explains the increasing number of inquiries. A good deal of spot business is being consummated, however. While much of the trading in heavy chemicals on the mid-West market still gives signs of mere hand-to-mouth buying, the feeling also is creeping in that prices in most branches of the market have reached the bottom and that henceforth any fluctuations will have an upward tendency.

In the lines where higher prices are being asked than was the case a fortnight ago, buyers are reluctant to meet the advance and the market has developed an endurance test between buyers and sellers. Sales are reported at the higher prices, though admittedly few, but the interest in the market at the range of a week or two ago is keener and the general tone of the St. Louis market is firmer.

SULPHURIC ACID:—The demand for this chemical is characterized as very strong, especially from the fertilizer manufacturers. These interests have held aloof from the market for some time, awaiting the traditional "good time to buy." Indications are that they consider that time here or close at hand, for both orders and bona fide inquiries are reported more numerous and involving greater tonnage than has been the case for many months. The 60 per cent grade is now quoted at $12.50 to $14, according to quantity; 66 per cent sulphuric acid is held at $18 a ton. The higher degree of this acid, oleum, is quoted at $25 a ton and is reported in good demand on the part of dye and explosives interests. It is understood here that the increasing scope of operations in the oil well fields has produced a strong demand for torpedoes which in turn is being reflected in the sales of sulphuric acid.

MURIATIC ACID:—A satisfactory amount of business is being transacted in this line, producers claim. The price is stationary at $22 a ton for the 18 per cent grade, but is more firm than was the case a few weeks ago.

SODIUM SULPHATE (Salt Cake):—Greater activity is reported in this branch of the market, too, with prices varying between $19 and $20 a ton.

SODIUM BISULPHATE (Niter Cake):—Business in this department is reported slightly improved, some deals having been transacted at $4 to $5 a ton.

NITRIC ACID:—The market for this chemical is not showing great activity, the prevailing quotation for 38 Baumé being 10 @ 10½c. per pound.

ZINC CHLORIDE:—The demand for this product from the manufacturers of creosoting oils continues unabated, due to the heavy Government orders for railroad ties.

ZINC OXIDE:—An unusual situation is reported in the local zinc oxide market, namely, that for the first time in more than a year the market is extremely active during the period when the announcement of quarterly price changes is expected momentarily. Under ordinary conditions the weeks preceding the expected announcement of new prices are practically devoid of business. This week and last, however, heavy sales of zinc oxide both for domestic and foreign account are reported at 8 to 9c. per lb., according to lead sulphate contents, in carload lots and 8½ to 9½c. per lb. in less than carload lots.

Chicago, June 10.

Gradual improvement in local trade conditions which were noted last month are continuing as June advances, with no spectacular changes in any line except flotation oils. With gross sales for the month figuring up to a comfortable total, collections getting in better shape and a knowledge that overstock and second hands have been reduced to a point where manufacturing conditions have some bearing on prices, the outlook, from the jobbers' standpoint, is more favorable than it has been at any time since last November.

Inquiries are plentiful and sales are being made in reasonable quantity. As yet, however, no long term contracts are being made, jobbers themselves being disinclined to tie up for any great time on the basis of existing low prices.

With 66-deg. sulphuric holding at $20, with sales in normal quantities, practically the entire line of heavy chemicals remains very firm. Sodium hydroxide (caustic soda) is up about 30c., now selling at $2.80, while sodium bichromate, under light demand, has fallen a little, to 7¾c.

No appreciable changes have occurred in the coal-tar line, benzol still selling at 25c. A considerable market for benzol had developed in garage sales to auto owners, when benzol was cheaper than gasoline, but now that the price is higher, this selling has ceased. Commercial demands are sufficient to hold the price firm, however.

Vegetable oils remain very firm in price, with the market rapidly absorbing all offerings.

Two cents has been added to the price of the best grade of steam distilled pine oil, and turpentine has been imitating a rocket, the price on crude advancing 2 or 3c. every day for the past two weeks, and now ranging from $1.05 to $1.10. This has been caused by heavy demand and a stock on hand of only about one-third normal for this time of year. Jobbers are a unit, however, in believing present price to be too high, saying that 85 cents will probably be the figure at which it will ultimately rest.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET JUNE 9, 1919

Acetic anhydride	lb.	$0.52 —	$0.60
Acetone	lb.	.15 —	.15½
Acid, acetic, 28 per cent	cwt.	2.50 —	3.00
Acetic, 56 per cent	cwt.	5.50 —	6.00
Acetic, glacial, 99½ per cent, carbnye	cwt.	12.00 —	14.00
Boric, crystals	lb.	.13½ —	.14½
Boric, powder	lb.	.13½ —	.14½
Hydrochloric, tech. 20 deg	cwt.	1.50 —	3.00
Hydrofluoric, 52 deg	lb.	.10 —	.11
Lactic, 44 per cent. tech	lb.	.14 —	.17
Lactic, 22 per cent. tech	lb.	.05 —	.06
Molybdic, C. P	lb.	4.50 —	5.50
Nitric, 40 deg	lb.	.07 —	.08
Nitric, 42 deg	lb.	.07 —	.08
Oxalic, crystals	lb.	.23 —	.28
Phosphoric, Ortho, 50 per cent. solution	lb.	.07½ —	.10
Picric	lb.	.30 —	.40
Pyrogallic, resublimed	lb.	2.45 —	2.55
Sulphuric, 60 deg., tank cars	ton	11.00 —	13.00
Sulphuric, 60 deg., drums	ton	17.00 —	.....
Sulphuric, 60 deg., carboys	ton	20.00 —	.....
Sulphuric, 66 deg., tank cars	ton	16.00 —	18.00
Sulphuric, 66 deg., drums	ton	21.00 —	.....
Sulphuric, 66 deg., carboys	ton	25.00 —	.....
Sulphuric, fuming, 20 per cent.(oleum) tank cars	ton	20.00 —	22.00
Sulphuric, fuming, 20 per cent.(oleum) drums	ton	25.00 —	.....
Sulphuric, fuming, 20 per cent.(oleum) carboys	ton	30.00 —	.....
Tannic, U. S. P	lb.	1.30 —	1.40
Tannic (tech.)	lb.	.42 —	.60
Tartaric, crystals	lb.	.82 —	.85
Tungstic, per lb. of WO_3	lb.	1.20 —	1.40
Alcohol, Ethyl	gal.	4.00 —	4.85
Alcohol, Methyl	gal.	1.25 —	1.30
Alum, ammonia lump	lb.	.03½ —	.04½
Alum, potash lump	lb.	.08½ —	.10
Alum, chrome lump	lb.	.15 —	.....
Aluminium sulphate, commercial	lb.	.01½ —	.03
Aluminium sulphate, iron free	lb.	.02½ —	.03
Aqua ammonia, 26 deg., carboys	lb.	.06½ —	.08
Ammonia, anhydrous, cylinders (100-150 lb.)	lb.	.30 —	.....
Ammonium carbonate, powder	lb.	.12½ —	.13½
Ammonium chloride, granular(white salammoniac)	lb.	.13 —	.14
Ammonium chloride, granular(gray salammoniac)	lb.	.13 —	.14
Ammonium nitrate	lb.	.17 —	.20
Ammonium sulphate	lb.	.05½ —	.06
Amyl acetate	gal.	3.50 —	3.75
Arsenic, oxide, lumps	lb.	.09 —	.09½
Arsenic, sulphide, powdered	lb.	.30 —	.32
Barium chloride	ton	80.00 —	90.00
Barium dioxide (peroxide)	lb.	.19 —	.24
Barium nitrate	lb.	.10 —	.11
Barium sulphate (precip.) (blanc fixe)	lb.	.01½ —	.03
Bleaching powder (see calcium hypochlorite)		..... —	.....
Blue Vitriol (see copper sulphate)		..... —	.....
Borax (see sodium borate)		..... —	.....
Brimatone (see sulphur, roll)		..... —	.....
Bromine	lb.	.40 —	.50
Calcium acetate	lb.	.02 —	.02½
Calcium carbide	lb.	.05½ —	.06
Calcium chloride, fused, lump	ton	19.00 —	25.00
Calcium chloride, granulated	lb.	.01¼ —	.02
Calcium hypochlorite (bleaching powder)	cwt.	1.25 —	2.00
Calcium peroxide	lb.	1.50 —	1.70
Calcium phospbate, monobasic	lb.	.22 —	.23
Calcium sulphate, precipitated	lb.	.10 —	.20
Carboo bisulphide	lb.	.05½ —	.06
Carbon tetrachloride, drums	lb.	.11 —	.14
Carbonyl chloride (phosgene)	lb.	.75 —	1.00
Caustic potash (see potassium hydroxide)		..... —	.....
Caustic soda (see sodium hydroxide)		..... —	.....
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 —	.08
Cobalt oxide	lb.	1.60 —	1.65
Copperas (see iron sulphate)		..... —	.....
Copper carbonate, green precipitate	lb.	.28 —	.31
Copper cyanide	lb.	.65 —	.70
Copper sulphate, crystals	lb.	.07 —	.08
Cream of tartar (see potassium bitartrate)		..... —	.....
Epsom salt (see magnesium sulphate)		..... —	.....
Formaldehyde, 40 per cent	lb.	.20 —	.21
Glauber's salt (see sodium sulphate)		..... —	.....
Glycerine	lb.	.21 —	.23
Iodine, resublimed	lb.	4.25 —	4.30
Iron oxide, red	lb.	.03 —	.18
Iron sulphate (copperas)	cwt.	1.00 —	1.75
Lead acetate, normal	lb.	.12½ —	.15
Lead arsenate (paste)	lb.	.15 —	.18
Lead nitrate, crystals	lb.	.85 —	.86½
Litharge	lb.	.09½ —	.10½
Lithium carbonate	lb.	1.50 —	.....
Magnesium carbonate, technical	lb.	.12 —	.14
Magnesium sulphate, U. S. P.	100 lb.	2.70 —	2.85
Magnesium sulphate, commercial	100 lb.	2.50 —	2.60
Nickel salt, double	lb.	.13 —	.15
Nickel salt, single	lb.	.11½ —	.14
Phosgene (see carbonyl chloride)		..... —	.....
Phosphorus, red	lb.	.55 —	.65
Phosphorus, yellow	lb.	.26 —	.37
Potassium bichromate	lb.	.29 —	.33
Potassium bitartrate (cream of Tartar)	lb.	.52½ —	.55
Potassium bromide, granular	lb.	.49 —	.50
Potassium carbonate, U. S. P.	lb.	.65 —	.70
Potassium carbonate, crude	lb.	.11 —	.14
Potassium chlorate, crystals	lb.	.25 —	.31
Potaseium cyanide, 98-99 per cent	lb.	Nominal	
Potassium hydroxide (caustic potash)	lb.	.35 —	.45
Potassium iodide	lb.	3.30 —	3.40
Potassium nitrate	lb.	.19 —	.22
Potassium permanganate	lb.	.60 —	.65
Potassium prussiate, red	lb.	.80 —	.95
Potassium prussiate, yellow	lb.	.27 —	.40
Potassium sulphate	ton	225.00 —	.....
Rochelle salts (see sodium potas. tartrate)		..... —	.....
Salammoniac (see ammonium chloride)		..... —	.....
Sal soda (see sodium carbonate)		..... —	.....
Salt cake	ton	12.00 —	18.00
Silver cyanide	oz.	1.19 —	.....
Silver nitrate	oz.	.67 —	.69
Soda ash, light	100 lb.	$1.50 —	$1.75
Soda ash, dense	100 lb.	2.00 —	2.25
Sodium acetate	lb.	.06 —	.08
Sodium bicarbonate	100 lb.	2.25 —	2.50
Sodium bichromate	lb.	.07½ —	.09
Sodium bisulphate (nitre cake)	ton	5.00 —	10.00
Sodium bisulphite	lb.	.05 —	.07
Sodium borate (borax)	lb.	.07½ —	.08
Sodium carbonate (sal soda)	100 lb.	1.30 —	1.60
Sodium chlorate	lb.	.15 —	.18
Sodium cyanide	lb.	.30 —	.31
Sodium fluoride	lb.	.14 —	.15
Sodium hydroxide (caustic soda)	100 lb.	2.50 —	2.75
Sodium molybdate	lb.	2.50 —	.....
Sodium nitrate	100 lb.	4.07½ —	.....
Sodium nitrite	lb.	.11 —	.13
Sodium peroxide, powdered	lb.	.25 —	.30
Sodium phosphate, dibasic	lb.	.04½ —	.05
Sodium potassium tartrate (Rochelle salts)	lb.	.43 —	.45½
Sodium prussiate, yellow	lb.	.17½ —	.20
Sodium silicate, solution (40 deg.)	lb.	.01½ —	.02½
Sodium silicate, solution (60 deg.)	lb.	.02½ —	.04½
Sodium sulphate, crystals (Glauber's salts)	cwt.	1.25 —	1.50
Sodium sulphide, crystal, 60-62 per cent (conc)	lb.	.04½ —	.05
Sodium sulphite, crystals	lb.	.03½ —	.04
Strontium nitrate, crystals	lb.	.25 —	.28
Sulphochloride	lb.	.05 —	.05½
Sulphur, crude	ton	32.00 —	35.00
Sulphur dioxide, liquid, cylinders	lb.	.10 —	.12
Sulphur (sublimed), flowers	100 lb.	3.05 —	3.60
Sulphur, roll (brimstone)	100 lb.	2.70 —	3.15
Tin bichloride (stannous)	lb.	.22½ —	.25
Tin oxide	lb.	.60 —	.....
Zinc carbonate, precipitate	lb.	.18 —	.20
Zinc chloride, gran	lb.	.13½ —	.14
Zinc cyanide	lb.	.49 —	.50
Zinc dust	lb.	.09 —	.11
Zinc oxide, dry American	lb.	.09½ —	.11½
Zinc sulphate	lb.	.03¾ —	.04

Coal Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha naphthol, crude	lb.	$1.00 —	$1.10
Alpha naphthol, refined	lb.	1.40 —	1.50
Alpha naphthylamine	lb.	.40 —	.50
Aniline oil, drums extra	lb.	.22 —	.24
Aniline salts	lb.	.28 —	.33
Anthracene, 80% in drums (100 lb.)	lb.	.90 —	1.00
Benzaldehyde (f.f.c.)	lb.	1.00 —	1.15
Benzidine, base	lb.	1.00 —	1.15
Benzidine, sulphate	lb.	.90 —	1.10
Benzoic acid, U. S. P	lb.	1.00 —	1.10
Benzoate of soda, U. S. P	lb.	.95 —	1.10
Benzol, pure, water-white, in drums (100 lb.)	gal.	.24 —	.28
Benzol, 90%, in drums (100 lb.)	gal.	.23½ —	.27
Benzyl chloride, 95-97%, refined	lb.	.35 —	.40
Benzyl chloride, tech	lb.	.25 —	.35
Beta naphthol benzoate	lb.	4.00 —	4.50
Beta naphthol, sublimed	lb.	.75 —	.80
Beta naphthol, tech	lb.	.45 —	.55
Beta naphthylamine, sublimed	lb.	2.25 —	2.35
Cresol, U. S. P., in druma (100 lb.)	lb.	.18 —	.....
Ortho-cresol, in druma (100 lb.)	lb.	.23 —	.25
Creaylic acid, 97-99%, straw color, in druma	gal.	.85 —	.90
Creaylic acid, 95-97%, dark, in druma	gal.	.80 —	.85
Creaylic acid, 50%, first quality, drums	gal.	.60 —	.....
Dichlorbenzol	lb.	.07 —	.10
Diethylaniline	lb.	1.75 —	2.25
Dimethylaniline	lb.	.50 —	.57
Dinitrobenzol	lb.	.25 —	.30
Dinitroclorbenzol	lb.	.25 —	.28
Dinitronaphthaline	lb.	.45 —	.55
Dinitrotoluol	lb.	.38 —	.45
Dinitrophenol	lb.	.30 —	.32
Dip oil, 25% tar acids, car lots, in drums	gal.	.38 —	.46
Diphenylamine	lb.	.70 —	.75
H-acid	lb.	1.90 —	2.25
Metaphenylenediamine	lb.	1.20 —	1.80
Monochlorbenzol	lb.	.10 —	.14
Monoethylaniline	lb.	1.50 —	1.75
Naphthaline, crushed in bbls. (250 lb.)	lb.	.06 —	.08
Naphthaline, flake	lb.	.06½ —	.07½
Naphthaline, balls	lb.	.09¾ —	.10
Naphthionic acid, crude	lb.	1.00 —	1.25
Nitrobenzol	lb.	.13 —	.15
Nitro-naphthaline	lb.	.40 —	.45
Nitro-toluol	lb.	.17 —	.20
Ortho-amidophenol	lb.	6.00 —	.....
Ortho-dichlor-benzol	lb.	.15 —	.20
Ortho-nitro-phenol	lb.	1.25 —	.....
Ortho-toluidine	lb.	.40 —	.45
Ortho-nitro-toluol	lb.	.27 —	.40
Para-amidophenol, base	lb.	2.75 —	3.50
Para-amidophenol, H. Cl	lb.	3.00 —	3.25
Para-dichlor-benzol	lb.	.06 —	.10
Paranitraniline	lb.	1.00 —	1.25
Para-nitro-toluol	lb.	1.35 —	1.50
Paraphenylenediamine	lb.	3.00 —	3.25
Para toluidine	lb.	1.50 —	1.75
Phthalic anhydride	lb.	1.75 —	2.15
Phenol, U. S. P., druma (dest.), (240 lb.)	lb.	.08 —	.09
Pyridin	gal.	2.50 —	.....
Resorcin, technical	lb.	3.50 —	3.75
Resorcin, pure	lb.	6.50 —	7.75
Salicylic acid, tech., in bbls. (110 lb.)	lb.	.20 —	.30
Salicylic acid, U. S. P	lb.	.25 —	.35
Salol	lb.	.75 —	.80
Solvent naphtha, water white, in drums, 100 gal.	gal.	.20 —	.25
Solvent naptha, crude, heavy, in drums, 100 gal.	gal.	.18 —	.20
Sulphanilic acid, crude	lb.	.25 —	.30
Toluidine	lb.	2.15 —	2.50
Toluidine, mixed	lb.	.45 —	.80
Toluol, in tank cars	gal.	.22 —	.24
Toluol, in druma	gal.	.23 —	.30
Xylidine, drums, 100 gal	lb.	.40 —	.45
Xylol, pure, in drums	gal.	.37 —	.45
Xylol, pure, in tank cars	gal.	.35 —	.....
Xylol, commercial, in drums, 100 gal	gal.	.30 —	.40
Xylol, commercial, in tank cars	gal.	.30 —	.....

Waxes

Prices based on original packages in large quantities.

Beeswax, natural crude, yellow	lb.	$0.40	—	$0.43
Beeswax, refined, yellow	lb.	.45	—	.47
Beeswax, white pure	lb.	.62	—	.68
Carnauba, No. 1	lb.	.80	—	.85
Carnauba, No. 2, regular	lb.	.65	—	.72
Carnauba, No. 2, North Couotry	lb.	.55	—	.60
Carnauba, No. 3, North Country	lb.	.46	—	.48
Ceresin, yellow	lb.	.16	—	.18
Ceresin, white	lb.	.18	—	.20
Japan	lb.	.13	—	.19
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.06	—	.07½
Paraffine waxes, crude scale, 117-119 m.p.	lb.	.06	—	.07½
Paraffine waxes, crude scale, 124-126 m.p.	lb.	.07	—	.....
Paraffine waxes, refined, 118-120 m.p.	lb.	.08¼	—	.08¾
Paraffine waxes, refined, 123-125 m.p.	lb.	.08½	—	.09½
Paraffine waxes, refined, 128-130 m.p.	lb.	.09½	—	.10
Paraffine waxes, refined, 130-132 m.p.	lb.	.10½	—	.11
Paraffine waxes, refined, 133-135 m.p.	lb.	.11½	—	.12
Paraffine waxes, refined, 135-137 m.p.	lb.	.12½	—	.....
Stearic acid, single pressed	lb.	.18	—	.19
Stearic acid, double pressed	lb.	.20	—	.21
Stearic acid, triple pressed	lb.	.22	—	.24
Spermaceti	lb.	.30	—	.32

Flotation Oils

All prices are f.o.b. New York, unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp. gr., 0.930-0.940	gal.	$0.70	
Pine tar oil, ref., sp. gr. 1.025-1.035	gal.	.45	
Pine tar oil, ref., sp. gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla.	gal.	.33	
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.	.58	
Pine tar, ref., thin, sp. gr., 1.080-1.960	gal.	.34	
Turpentine, crude, sp. gr., 0.900-0.970	gal.	.61	
Hardwood oil, f.o.b. Mich., sp. gr., 0.960-0.990	gal.	.24	
Hardwood oil, f.o.b. Mich., sp. gr., 1.06-1.08	gal.	.24	
Pinewood creosote, ref	gal.	.48	

Naval Stores

The following prices are f.o.b., New York, for carload lots.

Rosin B-D, bbl	280 lb.	$11.60	—	$12.25
Rosin E-I	280 lb.	12.20	—	12.45
Rosin K-N	280 lb.	14.10	—	14.45
Rosin W. G.-W. W	280 lb.	15.30	—	15.65
Wood rosin, bbl	280 lb.	11.95	—	.....
Spirits of turpentine	gal.	1.04	—	1.06
Wood turpentine, steam dist	gal.	.90	—	.....
Wood turpentine, dest. dist	gal.	.80	—	.....
Pine tar pitch, bbl	200 lb.	8.00	—	8.25
Tar, kiln burned, bbl. (500 lb.)	bbl.	12.50	—	13.50
Retort tar, bbl	280 lb.	13.50	—	14.50
Rosin oil, first run	gal.	.68	—	.78
Rosin oil, second run	gal.	.70	—	.80
Rosin oil, third run	gal.	.82	—	.83
Rosin oil, fourth run	gal.	.85	—	.95

Solvents

73-76 deg., steel bbls. (85 lb.)	gal.	$0.33½	
70-72 deg., steel bbls. (85 lb.)	gal.	.31½	
68-70 deg., steel bbls. (85 lb.)	gal.	.30½	
V. M. and P. naphtha, steel bbls. (85 lb.)	gal.	.23½	

Oils

VEGETABLE

Unless otherwise noted, the following prices are f.o.b., New York.

Castor oil, No. 3, in bbls	lb.	$0.19	—	$0.20
Castor oil, AA, in bbls	lb.	.21	—	.22
China wood oil, in bbls	lb.	.20	—	.22
Cocoanut oil, Ceylon grade, in bbls	lb.	.17	—	.17½
Cocoanut oil, Cochin grade, in bbls	lb.	.18½	—	.19½
Corn oil, crude, in bbls	lb.	.19½	—	.20½
Cottonseed oil, crude (f.o.b. mill)	lb.	.17½	—	.20
Cottonseed oil, summer yellow	lb.	.25	—	.26
Cottonseed oil, winter yellow	lb.	.26	—	.27
Linseed oil, raw, car lots	gal.	1.60	—	1.70
Linseed oil, raw, tank cars	gal.	1.52	—	1.56
Linseed oil, boiled, car lots	gal.	1.58	—	1.60
Olive oil, commercial	gal.	2.10	—	2.25
Palm, Lagos	lb.	.16½	—	.18
Palm, bright red	lb.	.16	—	.17
Palm, Niger	lb.	.15	—	.16
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.22	—	.23
Peanut oil, refined, in bbls	lb.	.26	—	.27
Rapeseed oil, refined in bbls	gal.	1.50	—	1.55
Rapeseed oil, blown, in bbls	gal.	1.58	—	1.60
Soya bean oil (Manchurian), in bbls., N. Y.	lb.	.17½	—	.18
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.15½	—	.15½

FISH

Winter pressed Menhaden	gal.	$0.90	—	$0.92
Yellow bleached Menhaden	gal.	.92	—	.93
White bleached Menhaden	gal.	.94	—	.95
Blown Menhaden	gal.	1.00	—	1.02

Miscellaneous Materials

All Prices f.o.b., N. Y.

Barytes, domestic, white, floated	ton	$25.00	—	$36.00
Barytes, off color	ton	22.00	—	27.00
Blanc fixe, dry	lb.	.03½	—	.04½
Blanc fixe, pulp	ton	30.00	—	45.00
Casein	lb.	.16	—	.18
Chalk, English, extra light	lb.	.05	—	.07
Chalk, English, light	lb.	.04½	—	.06
Chalk, English, dense	lb.	.04	—	.05
China clay (Kaolin), imported, lump	ton	35.00	—	.....
China clay (Kaolin), imported, powdered	ton	60.00	—	.....
China clay (Kaolin), domestic, lump	ton	10.00	—	20.00
China clay (Kaolin), domestic, powdered	ton	25.00	—	40.00
Feldspar	ton	11.00	—	15.00
Fluorspar, acid grade, lump, f.o.b. mines	net ton	$30.00	—	$35.00
Fluorspar, acid grade, ground, f.o.b. mines	net ton	35.00	—	40.00
Fuller's earth, domestic, powdered	ton	30.00	—	40.00
Fuller's earth, imported, powdered	ton	.....	—	.....
Pumice stone, imported	lb.	.03	—	.06

Talc, domestic	ton	16.00	—	60.00
Talc, imported	ton	55.00	—	60.00

Refractories

Following prices are f. n. b. works:

Chrome brick	net ton	90–100 at Chester, Penn.
Chrome cement	net ton	45–50 at Chester, Penn.
Clay brick, 1st quality fireclay	net ton	35–45 at Clearfield, Penn.
Clay brick, 2nd quality	net ton	30–35 at Clearfield, Penn.
Magnesite, dead burned	net ton	50–55 at Chester, Penn.
Magnesite brick, 9 x 4½ x 2½ in.	net ton	80–90 at Chester, Penn.
Silica brick	net ton	41–45 at Mt. Union, Penn.

Ferro-alloys

All prices f. o. b. works.

Ferro-carbon-titaaium, 15-18%, f.o.b. Niagara Falls, N. Y	net ton	$220.00	—	.....
Ferro-chrome, per lb. of Cr. contained, 6–8% carbon	lb.	32	—	$0.40
Ferro-chrome, per lb. of Cr. contained, 2–4% carbon	lb.	.70	—	.....
Ferro-manganese, 70-80% Mn	gross ton	100.00	—	125.00
Spiegeleisen, 16-20% Mn	gross ton	40.00	—	50.00
Ferro-molybdenum, per lb. of Mo	lb.	2.50	—	3.00
Ferro-silicon, 50%	gross ton	90.00	—	115.00
Ferro-silicon, 75%	gross ton	150.00	—	175.00
Ferro-silicon, 10–15%	gross ton	45.00	—	60.00
Ferro-tungsten, 70-80%, per lb. of contained W	lb.	1.30	—	1.60
Ferro-uranium, 35-50% of U	lb.	7.00	—	.....
Ferro-vanadium, 30-40%, per lb. of contained V.	lb.	5.50	—	7.00

Resales and overstocks make above prices approximate.

Ores and Semi-finished Products

Chrome ore, 35-40%, Cr_2O_3	unit	$0.70		
Chrome ore, 48% and over	unit	1.00	—	$1.25
Coke, foundry, f.o.b. mines	net ton	4.50	—	5.00
Coke, furnace, f.o.b. mines	net ton	4.00	—	5.00
Petroleum coke, f.o.b. Atlantic seaboard	net ton	16.00	—	16.50
Fluorspar, gravel, f.o.b. mines	net ton	20.00	—	25.00
Manganese ore, 45% Mn and over	unit	.75	—	.85
Manganese ore, chemical (MnO_2)	gross ton	60.00	—	70.00
Molybdenite, 85% MoS_2, per lb. of MoS_2	lb.	.75	—	.85
Tungsten, Scheelite, 60% WO_3 and over per unit of WO_3	unit	9.00	—	10.00
Tuogsten, Wolframite, 60% WO_3 and over, per unit of WO_3	unit	6.50	—	8.00
Uranium oxide, 96%	lb.	.....	—	.....
Vanadium pentoxide, 99%	lb.	6.00	—	.....
Pyrites, foreign, lump	unit	.17	—	.....
Pyrites, foreign, fine	unit	.17	—	.....
Pyrites, domestic, fine	unit	.14	—	.....
Ilmenite, 50% TiO_2	net ton	30.00	—	.....
Rutile, 95% TiO_2	net ton	200.00	—	.....
Carnotite, minimum 2% U_3O_8, per lb. of U_3O_8	lb.	3.00	—	3.25

Resales and overstocks make above prices approximate.

Plant Materials and Supplies

In carload lots, New York, unless otherwise stated.

BUILDING MATERIALS

Portland cement, at dock, without baga	bbl.	$2.30
Lump lime, common, including container	300 bbl.	2.65
Common brick, at dock	M.	15.00
Hollow building tile, } 8x12x12	M.	194.40
At factory, Perth Amboy, N. J. } 12x12x12	M.	291.60
Yellow pine, 3x4 to 8x8, 20-24 ft. long	M.	40.00
Yellow pine, 3x4 to 8x8, 20-24 ft. long at Chicago	M.	39.50
Yellow pine, 3x4 to 8x8, 20-24 ft. long at St. Louis	M.	37.00
Roofinga, tar felt (14 lb. per 100 sq.ft.)	ton	50.00
Roofinga, tar pitch (in 400-lb. bbl.)	ton	19.00
Roofings, asphalt pitch	ton	30.00
Roofings, asphalt felt	ton	65.00
Roofings, slate-surfaced shingles, per roll of 108 sq.ft.		2.10
Roofings, slate-finished shingles, 100 sq.ft.		5.50
Linseed oil, raw in barrels	gal.	1.76
Linseed oil, 5 gal. cans	gal.	1.89
Red lead, dry, 100 lb. keg	lb.	.13
Red lead, in oil, 100 lb. keg	lb.	.14½
Red lead, dry, 5 lb. cans	lb.	.15
Red lead, in oil, 5 lb. cans	lb.	.16½
White lead, dry and in oil, 100 lb. keg	lb.	.13¼
White lead, dry and in oil, 25 and 50 lb. kegs	lb.	.13½
White lead, dry and in oil, 5 lb. cans	lb.	.15

STRUCTURAL STEEL, MILL, PITTSBURGH

Beams and channels, 3 to 15-in	100 lb.	$2.45
Angles, 3 to 6-in., ¼-in. thick	100 lb.	2.45
Tees, 3-in. and larger	100 lb.	2.45
Plates	100 lb.	2.66
Rivets, structural, ⅞-in. and larger	100 lb.	4.20
Rivets, conchead for boilers, ⅞-in. and larger	100 lb.	4.30
Sheets, No. 28 black	100 lb.	4.35
Sheets, No. 10 blue annealed	100 lb.	3.55
Sheets, No. 28 galvanized	100 lb.	5.70

For painted corrugated sheets, add 30c. per 100 lb. for 25 to 28 gage; 25c. for 19 to 24 gage; for galvanized corrugated sheets, add 15c., all gages.

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

CALVERT—The National Reduction Co. plans to build a rosin and turpentine plant. A. D. Little, Inc., 30 Charles River Rd., Cambridge, Mass., architect.

Arizona

HILLTOP—The Ajax Metal Mining Co. plans to build a 150-ton flotation mill. N. P. Wilson, manager.

HILLTOP—The Hilltop Mining & Smelting Co. plans to build a smelter. O. Fife, manager.

MESA—The City Council plans an election soon to vote on $60,000 bonds for extensions to the gas plant, etc.

California

AVALON—The city plans election soon to vote on $55,000 bonds for the construction of a gas plant on Catalina Island, here.

BENICIA — Kulman, Salz & Co., 603 Wells-Fargo Bldg., San Francisco, is having plans prepared by J. A. Wilcox, engineer, c/o owner, for the construction of a 3-story, 103 x 154-ft. tannery. Estimated cost, $60,000.

JULIAN—F. Tolbat Co., 2115 Logan Ave., San Diego, plans development at its mine here, to include the construction of a mill having a daily capacity of 20 tons. J. W. Lyons, supt.

Connecticut

EAST LYME—The White Beach Sanatorium, c/o Dr. S. J. Maher, 212 Orange St., New Haven, plans to build a sewage disposal plant at the sanatorium for tubercular children. Ford, Buck & Sheldon, Inc., 60 Prospect St., Hartford, engineers.

Florida

JACKSONVILLE — The Virginia-Carolina Chemical Co., 11 South 12th St., Richmond., Va., has awarded the contract for the construction of a 46 x 240-ft. factory on Mills St., here, to Huggers Bros., Bill Bldg., Montgomery, Ala. Estimated cost, $250,000. Noted April 1.

Georgia

ATLANTA — Adair & McCarty Bros., Walton Bldg., are having plans prepared by Lockwood, Greene & Co., engineers, Healy Bldg., for improvements to the fertilizer plant, including a new acidulating unit. Estimated cost, $25,000.

Illinois

VENICE—The Barber Asphalt Co. has awarded the contract for the construction of an oil refinery, to the Fruin-Colnon Construction Co., Merchants-Laclede Bldg., St. Louis, Mo. Estimated cost, $150,000.

WOOD RIVER—The White Star Refining Co., Avery and Grand Trunk Ry., has purchased a site and plans to build a petroleum refinery and pipe line from Wood River to the Mississippi River. Estimated cost, $300,000.

Iowa

FAIRPORT—The Commissioner of Fisheries, Department of Commerce, Washington, D. C., received bids for the construction of a laboratory building at the Biological Station here, from the Walsh Construction Co., 114½ West 3rd St., Davenport, $82,000; J. W. Hopp, 403 Granby Bldg., Cedar Rapids, $84,000; J. Solar, 5th and Cedar Sts., Davenport, $88,000. Noted May 15.

Kansas

ARKANSAS CITY—The city will soon award the contract for the construction of sanitary sewers and a disposal plant. C. E. McCrae, Republic Bldg., Kansas City, Mo., engineer.

Maryland

BALTIMORE—Johns Hopkins University, 321 Druid Hill Ave., has awarded the contract for the construction of a 1-story, 50 x 150-ft. addition to its chemical laboratory on Charles Street Ave., to Frainie Bros. & Haigley, 18 Clay St. Estimated cost, $55,000.

CURTIS BAY (Baltimore P. O.)—The Associated Chemical Co., Pennington Ave. and Cabin Branch, has awarded the contract for the construction of a 1-story, 96 x 100 x 155-ft. fertilizer factory, to W. G. Gischel & Co., South Baltimore. Estimated cost, $9600.

SALISBURY—The Farmers & Planters Co., c/o W. P. Ward, 406 Main St., plans to build a 1- and 2-story, 70 x 225-ft. fertilizer plant and warehouse; bone grinders and other fertilizer plant machinery will be installed in same. Estimated cost, $20,000.

SPARROWS POINT—The Bethlehem Steel Corp. plans to double the size of its tinplate plant here, increasing the number of sheet mills by twelve; also build an additional open-hearth furnace. Estimated cost, $25,000,000.

Michigan

SAGINAW—The McNally Vulcanizing Co., 408 Germania St., is having plans prepared by Cowles & Mutcheller, architects, Chase Block, for the construction of a 1-story, 25 x 60-ft. factory on North Park Ave. Plans include the installation of modern machinery for vulcanizing and tire repair work.

Minnesota

INTERNATIONAL FALLS—The city will soon receive bids for the construction of a hydrogen gas plant. Estimated cost, $75,000. W. Glenn, Minneapolis, engineer.

SHERBURN—E. E. Risley, village recorder, will receive bids until June 27 for the construction of a sewage disposal plant, etc. A. Fick, Boone, Ia., engineer.

ST. PAUL—The city will soon receive bids for a septic tank for the sewage disposal plant at Field and Sheridan Aves., 70 x 120-ft., 17 ft. below grade, walls 3 ft. 6 in. thick at bottom, 16 in. thick at grade. C. A. Hausler, City Hall, engineer.

WALNUT GROVE—D. A. Malloy, city clerk, will receive bids in July for the construction of a sewer and a disposal tank. Estimated cost, $50,000. Druar & Smith, 513 Globe Bldg., St. Paul, engineers.

Missouri

LOHMAN—The American Barytes Co., incorporated by W. C. Irwin, J. Hays and others of Jefferson City, plans to build a mill. Estimated cost, $10,000.

ST. LOUIS—The Scullin Steel Co., 6700 Manchester Ave., will build a steel rolling mill at 6700 Knox Ave., having a monthly capacity of 10,000 tons. Estimated cost, $2,000,000. Peril & Marshall, 2 Rector St., New York City, N. Y., engineers.

ST. LOUIS—The United Drug Co., 63 Leon St., Boston, Mass., plans to build an 8-story factory for the manufacture of rubber goods, drugs, etc., at San Francisco Ave. and Kings Highway. Estimated cost, $2,000,000. F. N. De Rosset, general manager.

Montana

CUT BANK—The City Council will soon award the contract for the construction of a sewerage system, to include two sewage disposal plants, septic tank, etc. Estimated cost, $48,000. H. P. Walter, Minot Bldg., Great Falls, engineer.

New Jersey

KEARNY (Arlington P. O.)—The White Tar Co. will soon receive bids for the construction of a 2-story, 100 x 200-ft. office building and factory. Estimated cost, $60,000. J. W. Cowper Co., Fidelity Bldg., Buffalo, N. Y., engineer.

LAMBERTVILLE—The Chemung Iron & Steel Co., 39 Cortlandt St., New York City, plans to build a 1-story, 100 x 380-ft. steel rolling mill here. Estimated cost, $100,000. E. F. Quirk, c/o owner, engineer.

NEWARK—The Patton Paint Co., Chester Ave., plans to build a 2-story, 61 x 121-ft. factory. Estimated cost, $65,000. J. H. & W. Ely, Fireman Bldg., architects and engineers.

New York

BROOKLYN—The Germania Importing Co., 41 Union Sq., New York City, will build a 2-story, 40 x 90-ft. chemical factory at 46th St. and 2nd Ave. Estimated cost, $20,000. O. Ullrich, 371 Fulton St., architect.

BROOKLYN—H. Kohnsten, 537 Columbia St., manufacturer of chemicals, has awarded the contract for the construction of a 1-story, 60 x 100-ft. factory on Columbia St., to Post & McCord, 101 Park Ave., New York City. Estimated cost, $30,000.

EASTWOOD—The Syracuse Rubber Co., Thompson Rd., Syracuse, recently incorporated with $3,000,000 capital, has awarded the contract for the construction of a 3-story, 60 x 200-ft. plant for the manufacture of cord tires for automobiles, to the Shane Steel Construction Co., 2109 Midland Ave., Syracuse.

JOHNSON CITY—Cook, Holland & Russell will soon award the contract for the construction of a factory on Grand Ave. for the manufacture of concrete building blocks. Complete equipment will be installed in same. Estimated cost, $40,000.

PHILADELPHIA—F. X. Baumert Co., Antwerp, is having plant prepared for the construction of a modern milk testing plant and cheese factory. Laboratory equipment will be installed in same. Estimated cost, $30,000.

North Carolina

NAVASSA—The Morris Fertilizer Co., Third National Bank Bldg., Atlanta, Ga., has awarded the contract for the construction of a fertilizer plant, mill building, niter house, etc., to the Elliott Building Co., Hickory. Estimated cost, $450,000.

STATESVILLE—The city plans to extend the water and sewer mains, to include the installation of additional filters, etc. Estimated cost, $150,000. L. B. Bristol, Mayor.

WILMINGTON—The Morris Fertilizer Co., Third National Bank Bldg., Atlanta, Ga., has awarded the contract for the construction of a fertilizer plant, having a capacity of 75,000 tons a year, to the Elliott Building Co., Hickory. Estimated cost, $125,000. Noted March 15.

Ohio

COLUMBUS—The board of trustees of the Ohio State University will soon award the contract for the construction of a 1-story, 140 x 205-ft. chemistry building on the campus. Estimated cost, $85,000. J. N. Bradford, c/o Ohio State University, architect.

COLUMBUS—The Columbus Tire & Rubber Co., Hayden Bldg., plans to build a 1-story, 100 x 340-ft. rubber factory on West Goodale St. Estimated cost, $92,000. Austin Construction Co., East 152nd St., Cleveland, architect.

COLUMBUS—The Henderson Tire & Rubber Co., Bucyrus, has awarded the contract for the construction of a 2-story, 100 x 300-ft. rubber factory on Goodale St., here, to Moor Bros., 1358 Franklin Ave. Estimated cost, $100,000.

ST. PARIS—The city will soon receive bids for the construction of a sewage disposal plant, to include a filter bed and septic tank. Estimated cost, $10,000. P. Lethig, Springfield, engineer.

Oklahoma

OKLAHOMA—The Hazelrigg Laboratories, recently incorporated with $50,000 capital, by J. E. Harbison, treasurer, 310 Mercantile Bldg., and others, plans to build a plant for the manufacture of chemicals.

TULSA—The Hofstra Manufacturing Co., manufacturer of insect powder, plans to install machinery in its plant. Estimated cost, $30,000. J. B. Gibbons, engineer.

TULSA—Dr. L. D. Latham, Bliss Bldg., plans to install a chemical laboratory in connection with the 3-story, 40 x 120-ft. hospital which he plans to build at 18th

and Quincy Sts. Total estimated cost, $100,000. Thompson & Fleming, 222½ Iowa Bldg., architects.

Oregon

CORVALLIS—J. Myers, secretary of the Board of Regents of the State Agricultural College, will soon award the contract for the construction of a 2-story, 56 x 220-ft. engineering laboratory on the college campus. Estimated cost, $130,000. J. V. Nennes, 1040 Chamber of Commerce Bldg., Portland, architect.

PORTLAND — The Portland Rubber Mills, Inc., 368 East 9th St., has awarded the contract for the construction of a 1-story, 75 x 200-ft. factory in South Portland, to T. Muir, Henry Bldg. Estimated cost, $20,000.

SALEM—The Oregon Pulp & Paper Co. will soon receive bids for the construction of a two-machine paper and sulphite pulp mill on the Willamette River. Estimated cost, $1,000,000. C. E. Eaton, Sherman Bldg., Watertown, N. Y., engineer.

Pennsylvania

DEAN—The Haws Refractories Co., Johnstown, plans to build a large firebrick plant here, having a capacity of 100,000 bricks per day. H. L. Tredennick, Johnstown, president.

PHILADELPHIA — The Hess-Bright Manufacturing Co., Front and Erie Sts., plans to build a 2-story, 42 x 105-ft. laboratory. F. R. Watson, 1211 Walnut St., architect.

WISSINOMING—The Quaker City Rubber Co., 629 Market St., has awarded the contract for the construction of a 2-story, 140 x 160-ft. factory, to J. S. Rogers, Drexel Bldg., Philadelphia.

Texas

DALLAS—The State Refining Association, 1403 American Exchange National Bank Bldg., plans to build a skimming plant having a capacity of 500 barrels. S. Bonner, treasurer.

NORTH FORT WORTH—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of a helium production plant, to the Central Contracting Co., 520 Beatty Bldg., Houston. Estimated cost, $448,000.

WICHITA FALLS—The committee on Northwest Texas Insane Asylum will soon award the contract for the construction of four buildings for the asylum here, including disposal plant, etc. Estimated cost, $350,000. C. H. Page & Bros., Austin National Bank Bldg., Austin, architect.

Washington

HOQUIAM—The Western Rolling Mills Corp. will soon award the contract for the construction of the first unit of its steel rolling plant to be 70 x 300 ft. J. Johnson, manager.

West Virginia

CAMP HUMPHRIES — The United States War Department, Washington, D. C., will soon receive bids for the construction of an artificial gas plant and distribution system to serve 10,000 people. Lieutenant G. A. Caine, Camp Humphries, engineer.

FAIRMONT—The West Virginia Metal Products Corp., incorporated with $2,500,000 capital stock, plans to build a large brass rolling mill. J. E. Watson, president.

Wisconsin

SHEBOYGAN—The North Star Rubber Co., c/o L. Hoffmaster, 176 16th St., Milwaukee, plans to build a 2-story, 60 x 95-ft. rubber plant on Michigan Ave., here. Estimated cost, $45,000.

Alberta

CALGARY—The City Council has appropriated $350,000 for the construction of a sewage disposal plant.

Ontario

BANCROFT—The Canada Marble Co. plans to build a plant. Estimated cost, $500,000. Architect not selected.

DUNDAS—A. W. Draeseke, chairman of the sewer committee, will receive bids until June 23 for the construction of sewage disposal works, sewage pumping station and force main, out fall sewer, sewage pumping machinery, sprinkler equipment, etc. J. S. Fry, town, clerk. Noted May 1.

HAMILTON—The National Paper Goods Co., Ltd., plans to build a 56 x 100-ft. factory. Estimated cost, $80,000.

KITCHENER—The Imperial Oil Co., Ltd., 181 Brock St., Sarnia, has awarded the contract for the construction of an addition to its oil plant, here, to Shulte Bros. & Co., 35 Albion St., Brantford. Estimated cost, $20,000.

PORT COLBORNE—The Canada Cement Co., 273 Craig St., W., Montreal, Que., plans to build a potash recovering plant. Estimated cost, $150,000.

WELLAND—The Imperial Oil Co., 56 Church St., Toronto, has awarded the contract for the construction of an oil plant, to Schutz Bros., 35 Albion St., Brantford. Estimated cost, $40,000. Noted June 1.

WESTON—The K. & S. Canadian Tire & Rubber Co. is having plans prepared by Hynes, Feldman & Watson, architects, McKennon Bldg., Toronto, for the construction of a 1-story factory. Estimated cost, $80,000.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold its Fall meeting in Philadelphia, Pa., Sept. 2-6 inclusive.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its Fall meeting in Chicago, Sept. 23-25 inclusive.

THE AMERICAN ELECTRO-PLATERS' SOCIETY will hold its 1919 convention in Philadelphia, Pa., July 1-3.

THE AMERICAN FOUNDRYMEN'S ASSOCIATION will hold its 1919 convention in Philadelphia, Sept. 29 to Oct. 4.

THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its Summer meeting at Boston, Mass., June 18-21. A symposium is planned on electric furnaces.

THE AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its Fall meeting in Chicago, Ill., Sept. 22-27.

THE AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 22nd annual meeting at Atlantic City, N. J., June 24-27. The headquarters will be at the Hotel Traymore.

THE AMERICAN STEEL TREATERS' SOCIETY will hold its first annual convention in Chicago, Ill., Sept. 22-27.

THE FIFTH NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES will be held in Chicago, Ill., Sept. 22-27 inclusive.

THE INSTITUTE OF METALS DIVISION of the A. I. M. E. will hold its next meeting in Philadelphia, Pa., Sept. 29 to Oct. 4.

THE INSTITUTE OF METALS will hold its Autumn meeting in Sheffield, England, Sept. 24-25.

THE INTERALLIED CHEMICAL CONFEDERATION will hold its next meeting in London, July 15-18, 1919.

THE NATIONAL FERTILIZER ASSOCIATION will hold its 26th annual convention the week of June 23 at the Hotel Griswold, Eastern Point, New London, Conn.

THE SOCIETY FOR THE PROMOTION OF ENGINEERING EDUCATION will hold its 27th annual meeting at Johns Hopkins University, Baltimore, Md., June 25-28.

Industrial Notes

THE CHICAGO PNEUMATIC TOOL CO. has moved its Milwaukee office from Room 1305, Majestic Bldg., to Room 1418 in the same building, where more convenient quarters have been obtained.

THE PRATT ENGINEERING & MACHINE CO., Atlanta, Ga., has been awarded a contract for the erection of a complete fertilizer plant for the Southern Fertilizer & Chemical Co. at Savannah, to cost approximately $500,000. This new plant is to take the place of one recently destroyed by fire and will be ready for operation in September, 1919.

THE BLAW-KNOX CO., Pittsburgh, Pa., manufacturers of steel products, announces the appointment of Mr. J. E. Mason as manager of field sales. For the past four years Mr. Mason has been connected with the McGraw-Hill Co., having been in charge of the Chicago office of *Engineering News-Record* since July, 1917.

THE ANNISTON STEEL CO., Anniston, Ala., announces the appointment of W. W. Tarleton as director of the salvage division, sales department. Mr. Tarleton will be in charge of the sale of iron and woodworking machinery, engines and boilers and miscellaneous equipment recently acquired from the Illinois Car & Equipment Co.

THE BOOTH-HALL CO., designer and builder of electric furnaces, announces removal of the executive and sales office to Rooms 1007-1008 Hearst Bldg., 326 W. Madison St., Chicago, Ill.

THE ELECTROLABS CO., New York, announces that the Paschall Oxygen Co., Philadelphia, will increase the capacity of its plant 25 per cent, making a total of 1,000 Levin cells in operation.

THE AMERICAN STEAM CONVEYOR CORP., Chicago, Ill., announces the appointment of Mr. Charles H. Florandin, formerly of the National Electric and Welding Co., New York, as general manager of its Eastern territory, with headquarters at 110 W. 40th St., New York.

THE MARLAND REFINING CO., Ponca City, Okla., has recently advised its employees that it has determined on a plan for paying labor dividends based upon amount of salary or wages received. The management regards the labor of its employees as an investment by them in the business and will pay them a dividend of its earnings made by capital and their labor. This is said to be the first time that a plan of labor dividends has been tried in the oil business.

SCHAAR & CO., Chicago, Ill., announces the removal to larger quarters at 556-560 W. Jackson Blvd., where the manufacturing, selling and executive departments will be under one roof.

THE UNITED FILTERS CORP., New York, announces the appointment of Mr. C. B. Oliver as manager of the Chicago office with headquarters in the Peoples' Gas Building.

MR. JAMES INGLIS, president of the American Blower Co., sailed from New York on May 15 as a member of a commission appointed to confer with European cotton interests on post-war conditions in the cotton industry throughout the world and with special reference to the proposed world cotton conference to be held in New Orleans next October.

THE COMMITTEE OF THE AMERICAN INSTITUTE OF CHEMICAL ENGINEERS, of which Dr. R. F. Bacon, director of the Mellon Institute, is chairman, is assisting the Government in disposing of chemical plants and surplus stocks of chemicals and apparatus. Much of this material is difficult to store and must be sold at once.

MR. M. H. JONES, who has been connected with the Westinghouse Electric & Manufacturing Co. for the past fifteen years as assistant to the manager of the Philadelphia district, has resigned his position to become sales manager of the Standard Electric & Elevator Co. of Baltimore.

THE ALLIED MACHINERY CO. OF AMERICA has increased its capital stock to $5,000,000, the step being necessitated by the decision of the American International Corp. to group all of its machinery export selling subsidiaries under one head. The Allied Construction Machinery Corp. will be absorbed by the American Machinery Co. of America. The Allied Machinery Co. de France and the Allied Machinery Co. d' Italia will retain their corporate entities, but their parent corporation will be the Allied Machinery Co. of America rather than the American International Corporation as before. This is also true of the Horne Co., Ltd., of Japan, which was purchased early in the year by the American International Corporation. Mr. J. W. Hook will continue as president of the Allied Machinery Co. of America, in general charge of the business. Messrs. F. A. Monroe, S. T. Henry and T. G. Nee have been elected vice-presidents. Mr. Monroe is in charge of the administrative affairs of the company. Mr. Henry is in charge of sales and advertising and Mr. Nee is at present in Japan, devoting his attention to the affairs of the Horne Co., Ltd. Mr. R. P. Redier is general sales manager of the company, with headquarters at Paris.

HAMILTON & HANSELL, INC., New York City, announces the selling of the following electric furnaces: One 1000-lb. Rennerfelt furnace, 400 k.v.a., to the Steel Alloys Co. of America, to be erected at its plant in Bayway, Elizabeth, for the reduction of tungstic acid to metallic tungsten. One 1000-lb. Rennerfelt furnace, 200 k.v.a., to the British American Nickel Co., Ottawa, Canada, to be erected at its Deschene plant in Quebec, for melting nickel. One 150-k.v.a. single-phase pot furnace with its complete

equipment, sold to the Government of the Netherlands, Colonial Department, to be erected at the experimental station in Batavia, Java, Dutch East Indies.

LEEDS & NORTHRUP CO., Philadelphia, Pa., has opened a pyrometer sales and service department at 1304 Monadnock Block, Chicago. A complete standardization equipment will be maintained and certification of thermocouples and of pyrometer equipments will be furnished in terms of standards certified by the United States Bureau of Standards. Particular attention will be given to maintaining equipment after installation. The office will be in charge of Mr. Henry Brewer.

MARDEN, ORTH & HASTINGS, INC., of New York City, moved its dyestuff and intermediate department to Bound Brook, N. J. An office at 136 Liberty Street, New York City, will be maintained for the metropolitan salesmen of the dyestuffs and intermediates department, and also considerable stocks will be carried in New York for the quick deliveries to trade in that vicinity.

THE STANDARD ELECTRIC & ELEVATOR CO., INC., Baltimore, Md., has opened a New York office at 280 Broadway, in charge of C. A. Harrington, formerly sales manager of the company.

Directors of the E. I. du Pont Powder Co. have elected the following new vice-presidents: Charles A. Meade, W. S. Carpenter, Jr., J. B. D. Edge, A. Felix du Pont, William C. Spruance and Charles A. Patterson. These are the recently appointed members of the new executive committee, and their election as vice-presidents follows the custom of the company, which gives the title of vice-president to the active heads of departments.

THE BLAW-KNOX CO., Pittsburgh, Pa., has taken over the manufacture and field operation of the Unl-Form System of reinforced concrete floor and roof construction, which is now incorporated in the steel forms department of the Blaw-Knox Co. and will be known as "Blawforms."

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., East Pittsburgh, Pa., announces the appointment of Mr. H. L. Garbutt as manager of the supply division of the San Francisco office of the company.

THE CARBON STEEL CO., Pittsburgh, Pa., announces the return from the aviation service in Italy of Mr. Harry S. Finkenstaedt as Western sales agent.

THE ALKALI EXPORT ASSOCIATION, INC., New York, is composed of five companies: The Pennsylvania Salt Mfg. Co., Philadelphia; The Solvay Process Co., Syracuse, N. Y.; The Michigan Alkali Co., New York; Columbia Chemical Co., Cincinnati; The Hooker Electrochemical Co., Niagara Falls, N. Y.

THE BUFFALO FORGE CO. announces that Mr. C. C. Cheyney has returned to take charge of its Chicago office and store. Lieut. Cheyney was commissioned in the Navy and had charge of the mechanical repair shops at the Naval Aviation Station, Pensacola, Fla. Capt. H. H. Downes, 12th U. S. Engineers (Railway) has returned from France, and expects that after receiving his discharge he will take charge of the Buffalo Forge Co.'s interests in the St. Louis territory.

THE WHEELER CONDENSER & ENGINEERING CO., Carteret, N. J., manufactured and shipped during the month of April 879,900 lb. of seamless drawn brass, copper and tungsten tubes.

THE INTERNATIONAL OXYGEN CO., Newark, N. J., announces the appointment of Mr. Preston Belvin as district sales engineer, in charge of the Pittsburgh district sales work, with headquarters at 1310 National Bank Bldg. The Chicago office of this company has been moved from 223 Railway Exchange Bldg. to 817-820 Chicago Stock Exchange Bldg., with Mr. Philip G. Wesley in charge.

THE SCIENTIFIC UTILITIES CO., INC., New York, manufacturer of laboratory glassware and metal apparatus, with offices at 84 East 10th St., has raised its capital to $30,000.

THE BETSON PLASTIC FIRE BRICK CO., Rome, N. Y., elected Mr. Frank J. Jewell as president and secretary and Mr. Nelson Adams, vice-president and treasurer. The company's products are plastic firebrick for boiler furnace linings and baffle walls and Hi-heat cement for use in the boiler room.

THE CELITE PRODUCTS CO., New York City, announces the appointment of Mr. Edward F. Davis as sales engineer in Northern New Jersey on the application of Sil-O-Cel insulation and Filter-Cel for filtration.

Manufacturers' Catalogs

THE KINITE CO., Milwaukee, has issued a 4-page folder entitled "Kinite, A Patented Alloy Steel."

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., calls attention to a six-page folder on melting metal with electrically heated pots.

THE GRISCOLM-RUSSELL CO., New York: Bull. No. 230 illustrates and describes the Reilly water heater.

THE DENVER FIRE CLAY CO., Denver, Colo., calls attention to two new bulletins. Bull. No. 125 on firebrick, metallurgical tile, fire clay, etc., illustrates and describes these products. Bull. No. 100 treats metallurgical clay goods, muffles, crucibles and scorifiers.

THE BUCKEYE DRYER CO., INC., Columbus, Ohio: Cat. No. 3 is a new 44-page booklet which deals with Buckeye dryers for organic and inorganic materials. Many illustrations are given together with descriptive matter.

THE MERRILL CO., San Francisco, Cal., has issued a booklet which gives the comments of the technical press on the Crowe vacuum precipitation process, which is a new method of precipitating cyanide solutions in conjunction with either the Merrill precipitation process or with zinc boxes.

THE AMERICAN LAVA CO., Chattanooga, Tenn., announces a new publication entitled "Lava for Mechanical and Electrical Purposes." This 16-page booklet illustrates and describes nature and physical properties, mechanical properties, electrical properties, uses and cost and composition lava.

THE CHAS. A. SCHIEREN CO., New York City has just received from the press Cat. No. 10, issued April, 1919, on Schieren leather beltings. It is an attractive 40-page booklet dealing with tanning methods, the different qualities of belting, general price list on Duxbak leather belting, leather link belting with price list, round leather belting, wire-screwed solid round belting, cut lacing, hydraulic leather, belt cement wafers, waterproof cement and flyfoot belt dressing. Many illustrations are given in color to illustrate these products. Schieren Engineering Service is a section which give a definite plan for making belting cost less and go further.

New Publications

STANDARD SPECIFICATIONS FOR PURITY OF RAW LINSEED OIL FROM NORTH AMERICAN SEED. Industrial Standards No. 57, published by the Bureau of Foreign and Domestic Commerce.

NEW BUREAU OF STANDARDS PUBLICATIONS: Tech. Paper No. 126. A study of the Goutal method for determining carbon monoxide and carbon dioxide in steels. By J. R. Cain and Earl Pettijohn; No. 76. Aluminium and Its Light Alloys.

NEW UNITED STATES GEOLOGICAL SURVEY PUBLICATIONS: 1:1 Cadmium in 1918. By C. E. Siebenthal (Mineral Resources, 1918, Part 1), published May 8, 1919; 1:21. Gold and Silver in 1917. General Report. By H. D. McCaskey and J. P. Dunlop (Mineral Resources, 1917, Part 1), published May 9, 1919; 1:22. Antimony in 1917. By Edson S. Bastin (Mineral Resources, 1917, Part 1), published May 13, 1919; 11:28. Clay-Working Industries and Building Operations in the Larger Cities in 1917. By Jefferson Middleton. (Mineral Resources, 1917, Part 11), published May 12, 1919; 11:29. Lime in 1917. By G. F. Laughlin. (Mineral Resources, 1917, Part 11), published May 13, 1919.

U. S. DEPT. OF LABOR PUBLICATION on Treatment of Industrial Problems by Constructive Methods. A pamphlet and chart on methods of redesigning labor turnover and improving morale in plant organization.

SUGGESTIONS FOR IMPROVING PLANT ORGANIZATIONS. A report of a survey of 200 plants and works with suggestions for their improvement.

THE CALIFORNIA STATE MINING BUREAU, San Francisco, has issued Bull. 84, which is the third annual report of the State Oil and Gas Supervisor of California for the fiscal year 1917-18.

THE UNITED STATES NATIONAL MUSEUM, Bull. 102, Vol. 1. The Mineral Industries of the United States: The Energy Resources of the United States; A Field for Reconstruction. A survey of the situation in domestic fuels, petroleum and power, made in anticipation of the time when the United States must more systematically employ its energy resources.

Technology, The Journal of the Manchester Municipal College of Technology, Manchester, England. A record of investigations undertaken by members of the college.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 144. Report of a Joint Committee Appointed from the Bureau of Mines and the United States Geological Survey by the Secretary of the Interior to Study the Gold Situation; Tech. Paper 214. Motor Gasoline Properties, Laboratory Methods of Testing, and Practical Specifications. By E. W. Dean; War Minerals Investigations Series No. 12. The Jones Process for Concentrating Manganese Ores, Results of Laboratory Investigations. By Peter Christianson and W. H. Hunter; Minerals Investigations Series No. 13. Cost of Producing Ferro-Grade Manganese Ores. By C. M. Weld and W. R. Crane.
